MAXWELL, GEO. T., 133.
MILLARD, F. R., 163, 515.
MILLEN, S. R., 387.
MILLER, N. C., 754.
MILLS, C. K., Clinic, 174, 202, 286.
MISKIN, HANE, 486.
MITCHELL, W. F., 81.
MOORE, J. H., 81.
MOORE, R. L., 483.
MORRISON, W. H., Report, 63, 174, 202, 286, 313, 343.
MORTON, T. G., Clinic, 719.

NANCREDE, C. B., Clinic, 681.
NEFF, J., 530, 687.

OGDEN, W. M., 193.
OWINGS, J. H., 312.

PALMER, C. D., 146.
PARCELS, W. H., 25, 461.
PARISH, W. H., 529, 686.
PARK, A. V., 492, 498.
PARVIN, THEOPHILUS, 29, 494.
PEEBLES, H. P., 579.
PEPPER, W., Clinic, 313, 343, 591.
PINKSTON, J. M., 285.
PORTER, W., 556.

RAVOGLI, A., 654.
REAMY, T. A., 310, 620.
REYNOLDS, W. W., 219.
RILEY, F. C., 554.
RILEY, H. A., 276.
ROBINSON, O. C., 192.
ROOK, C. W., 431.

SEELYE, W. H., Report, 8.
SEGUIN, E. C., 650.
SIMPSON, GEO. B., 709.
SMITH, J. S., 169.
SMITH, SAMUEL W., 717.
SMITH, T. CURTIS, 55.
SNIVELY, I. N., 228.
STAMPS, JNO. A., 25, 197, 457.
STANLEY, T., Report, 120, 593.
STEWART, J. S., Report, 260.
STEWART, R. B., 331.
STEWART, W. S., Clinic, 260.
SUTTON, R. S., 147, 484.
SWARTZ, G. N., 284.
SWERINGEN, H. V., 132.

THOMAS, CHAS. HERMAN, 649.
THOMAS, J. J., 192.
TURNBULL, C. S., Report, 21, 47.
TURNBULL, L., 577, 610.
TYSON, JAMES, 549.

VARIAN, W., 451.
VAUGHAN, V. C., 200.

WALKER, J. B., 561.
WASHBURN, I. B., 709.
WAUGH, W. F., 172.
WEBER, LEONARD, 653.
WHITE, J. W., 687.
WILLARD DE FOREST, 85, 113.
WOOD, H. C., Clinic, 494.

YOUNG, J. G., 168.

ZENNER, PHILIP, 119.
ZINKE, E. G., 141.

INDEX.

Abdominal; surgery, 13, 624, 629; muscles, paralysis of, 464.
Ablation of half of tongue, 120.
Aborigines of South Formosa, habits and diseases of, 645.
Abortion, cases of, 722.
Abscess; hepatic, 63; of brain, 100; of breast, 135; perinephritic, 300; supra-orbital, 321; popliteal, 433; strumous, 434; syphilitic, of tibia, 564; mammary, 688; of liver, 697; hepatic, causes of, 704.
Abscesses; multiple, 719; hepatic, in Peru, 743, 755.
Absinthe, 389.
Absorption of mercury, 156.
Academy of Surgery of Phila., 756.
Acid; sulphurous, poisonous qualities of, 187; salicylic, in rheumatism, 328; in urticaria, 609; in diarrhœa, 673; pyrogallic, for psoriasis, 512.
Accident, singular, 607.
Accidents; during coition, 636; during coitus, 703.
Aconite poisoning, 192.
Acute; affections, cocaine in, 105; coryza, treatment of, 150; albuminuria, 131; dysentery, epidemic of, 197; nephritis, heart and pulse in, 329; diarrhœa, treatment of, 329; rheumatism, treatment of, 378, 438, 671, 676; idiopathic spinal myelitis, 474; Bright's disease, 493; croupous pneumonia, 504; meningitis following removal of cancerous cervix uteri, 506; gangrene of foot, 562; coryza, atropia in, 738.
Accoucheur resume practice, how soon? 90.
Adaptation of dietary, 195.
Addison's disease, 91.
Adherent secundines, treatment of, 722.
Administer medicine to swine, how to, 502.
Adolescence, cardiac disease in, 393.
Adulteration of food, 276.
Adventure of barber doctor, 517.
Albumen, testing for, 274, 482.
Albuminuria; acute, 131; puerperal convulsions without, 216; intermittent, without disturbance of health, 236; of syphilis, 267; cyclic, 637; post-mortem, 731.
Alcohol; habit, coca for, 510; in snake-bite, 547.
Alcoholic, 107; consumption in Belgium, 223; paralysis, 242; insomnia, pilocarpine in, 482.
Alcoholism; chronic, 481; monobrated camphor in, 576; vomiting in pregnancy due to, 630.
Alexander's operation, 681.
Alimentation of consumptives, 668.
Alkaloid in pickled cabbage, 616.
Amanitine and its antidote, 684, 713.
American literary work, aid from Germany to continue it, 324.
Amputation; of breast, 121; of toe, 532.
Ammonia: carbonate, use of, 442; in snake-bite, 547.
Amyl, nitrite for gout, 708.
Anæmia, arsenic in, 567.
Anæmic dropsy, 625.
Anæsthesia; through cauterization, 274; failure of cocaine to produce, 360; cocaine, 575, 606.
Anæsthetics in normal labor, 546.
Anæsthetic; water a local, 515; new, 669.
Ancient libraries and hygiene, 580.
Anatomy; of pericardium, 35; morbid, of pneumonia, 122.
Anchylosis, 593; of knee, 432.
Aneurism: obscure popliteal, 106; popliteal, 173; probable aortic, 403; of aorta, 403; of subclavian, 466; of common carotid, 475; gastric, 670.
Angioleucitis of leg, 466.
Angioma pigmentosum et atrophicum, 303.
Angustifolia yucca, examination of, 301.
Animation, suspended, 159.
Ankle; compound dislocation of, 404; joint, traumatic erysipelas at, 429.
Annual Report of Surgeon-General, 734.
Anomalous coronary artery of heart, 106.
Anorexia, 448.
Ante-mortem probate of wills, 276.
Antidote; for resorcin, 449; bag, 647; for amanitine, 684, 713.
Antiphlogistic touch of therapeutic knife, 574.
Antipyretic, latest, 736.
Antipyrin; a styptic, 477; in phthisis, 575; in hectic fever, 610; eruption after use of, 673.
Antipyrine; in sunstroke, 234; an incompatible of, 576.
Antiseptic; surgery, 53; system in obstetric practice, 219; the new, 553.
Antiseptics in midwifery, 739.
Anti-vaccination riots in Montreal, 388.
Antrum, sarcomatous tumor of, 404.
Anus mistaken for undilated os, 517.
Aorta; aneurism of, 403; aspiration of, 705.
Aphasia, syphilitic, 333.
Aphonia from inebriety, 601.
Apomorphine in croup and bronchitis, 547.
Apparatus, Franz Staffel's, for scoliosis, 225.
Arm; paralysis of, 464; contusion of, 466; presentation, expulsion of fœtus in, 640.
Arrested fœtal development, 698.
Arrow, injury of eye by, 696.
Arsenic; in burial soil, 140; in malarial fevers, 607; therapeutic value of, 567.
Arsenical wall-papers, jaundice from, 447.
Arteritis in typhoid fever, 707.
Artery; anomalous coronary, of heart, 106; subclavian, ligature of, 109; meningeal, treatment of, 599.
Arthritis of knee, 432.
Artificial; teeth in trachea, 67; may do damage, 678; nipples, 369; respiration in sunstroke, 575; joint, 593.

Artificially-fed infants, 386.
Aseptol, 610.
Aspergillus glaucus, 149.
Asphyxia, death from, 67.
Aspiration; of gall-bladder, 634; bladder, for retention, 675; of aorta, 705.
Aspirations, daily, in empyema, 72.
Asthma, 257; Germaine Sée on, 327; and bronchitis, 434; relief of, 639.
Astragalus; compound fracture of, 467; fracture of, 741.
Ataxia, locomotor, rare symptoms of, 546.
Ataxy from syphilis, 181.
Athletic judge, 421.
Athletics at University of Pennsylvania, 335.
Atlas, congenital dislocation and fracture of, 634.
Atrophicum, angioma pigmentosum et, 303.
Atropia in acute coryza, 738, 753.
Atropine, herpes following external use of, 707.
Atropo-morphia solutions, 505.
Aunt Betsy's "simpsons," 82.
Auscultation of vessel wounds, 410.
Axillary glands, removal of, 121.

Babies, mixed up, 307.
Baby milk, secretion in, 369.
Bacteria; in parturition, 34; and wells, 196.
Bag, an antidote, 647.
Balsam of fir, a dressing, 417.
Barber Doctor, adventure of, 47.
Baths, potash, permanganate of, 47.
Battey's operation, 289.
Bean, Calabar, 694.
Beard, wearing of, 582.
Beef, extract, poisonous? 541.
Beer kegs, dregs from, 421.
Beer, preservative, peroxide of hydrogen a, 549.
Belladonna, herpes following external use of, 707.
Beneficence of nature, 605.
Berlin, letter from, 643.
Beverages, twelve old-fashioned, 451.
Bichloride solution, suicide by, 358.
Bihydrobromate of quinia, 477.
Biliary colic, treatment of, 21.
Bill of fare, cow-boy's, 278.
Bilious fever, malignant, 133.
Biniodide of mercury, 10.
Binaural stethoscope, 663.
Birth, premature, 420.
Bismuth, subnitrate for dressings, 514.
Biting his tongue, 455.
Bladder; rupture of, 68; perforating ulcer, 183; tumors of, 272; removal of calculi from, 351; pencil in, 416; litholapaxy with cocaine, 543; supra-pubic aspiration of, 675.
Bled to death, 455.
Blindness, recovery of sight after, 98.
Blood; in urine, 263, 576; germs in healthy, 513.
Blunders, examination, 677.
Boils, boy's composition on, 677.
Borax an internal disinfectant, 547.
Boro-glyceride in skin diseases, 514.
Boulimia, 448.
Bowel, occlusion of, 434.
Boys, doctor, talks to, 679.
Brain; concussion of, 435; echinococci of, 480; wound of base of, 534; fungus of, 719.
Breast; amputation of, 121; abscess of, 135; cancer of, 707.
Bright's disease, 745; lemons in, 21; physiognomy of, 371; acute, 493; chronic, 625; prognosis in, 727.
Brightness, on vision, effects of, 710.
Bromide of ethyl, 374.
Bronchitis; and asthma, 434; chronic, hygiene of, 448; apomorphine in, 547.
Broncho-pneumonia, 321.
Bronchus, foreign body in, 414.
Bruises, ointment for, 642.
Buboes, opening, cocaine in, 47.
Buccalis leucoplakia, 356.
Bullet wound of heart, 742.
Bunion splint, 244.
Burial; soil, arsenic in, 140; *vs.* cremation, 579.
Burn; cicatrization due to, 433; extensive deformity after, 730.
Burns, 655.

Cabbage, pickled, alkaloid in, 616.
Calabar bean in treatment of traumatic tetanus, 694.
Calculi, removal from, 351.
Calculus; latent vesical, 184, an enormous, 223; renal, 631; prophylaxis of, 708.
Calomel, on conjunctiva, action of, 162.
Camphor; in Japan, 487; in alcoholism, 576.
Cancer; rectal, 397; of stomach, 406; gastric, diagnosis of, 515; hereditary; 674; of breast, 707.
Cancerous cervix uteri, 506.
Cannabine, tannate of, 21.
Capsicum in hemorrhoids, 574.
Carbonate of ammonia, use of, 443.
Carbuncle; sponge grafts for, 329; cure of, 635.
Carcinoma of uterus, 124; physiognomy of, 371; of knee, 497; disease of, 594; of neck, 594.
Cardiac disease in adolescence, 393.
Caries of both tibiæ, 121.
Carotid, common, aneurism of, 475.
Cascara sagrada, evidence for, 386.
Case; a remarkable, 238; a peculiar, 312; of empyema, 527; of pyrophobia, 694; spontaneous delivery, 696; abscess of liver, 697; placenta previa, 718; compound epiphysial diastasis, 730; exophthalmic goitre, 741; an interesting, 710.
Casein in cow's milk, 386.
Cases; rare in practice, 396, 429; of fracture of upper extremity, 717.
Catalepsy cured by perineorrhaphy, 703.
Cataract, operation for, 425.
Catarrh; chronic nasal, 319; vesical treatment of, 450.
Catheter; introducing, 24; catheters, metal, cleaning of, 676.
Catholic surgeons, to craniotomy, relations of, 222.
Cattle cars, disinfection of, 645.
Causes and prevention of insanity, 381.
Cauterization, anæsthesia through, 274.
Cautery-galvano, uses of, 172.
Caution about cocaine, 413.
Cellar ventilation, importance of, 679.
Cellars, damp, 702.
Cellulosis cysticercous, 563.
Cellulitis, pelvic in, 132.
Cephalalgia, treatment of, 375.
Cephalhæmatoma, intra-cranial, 715.
Cerebral localization, 126; surgery, 245; hemorrhage, carbonate of ammonia in, 442; infantile pneumonia, 508; palsies, 595.

Cerebro-spinal fever, 188.
Cerium, oxalate in vomiting of pregnancy, 545.
Cervical vertebra, fracture of, 463; glands, removal of, 594.
Cervix uteri; laceration of, 263; post partem, 380; laceration of, 496; cancerous, 506; Emmet's operation, 546.
Chancre; indurated of eyelid, 218; diagnosis of, 245.
Chest; cold sponging of, 504; development of, 558.
Chicken pox, 243
Child; living in lungs without air, 240; birth, vaginal injections after, 246; infected with diphtheria, 445.
Children; night cough in, 360; spasmodic paralysis in, 594.
Childhood, lymphatic leukæmia in, 617, 627.
Chinese emigration; restriction of, 163; problem, 269; materia medica, 454.
Chloride; of methyl, in neuralgia, 708; of rubidium, 708.
Chlorine, disinfection with, 447.
Chloroform; poisoning from, 130; cessation of respiration under, 440; insomnia produced by, 706.
Cholecystotomy, 731.
Cholera; treatment of, 42, 274, 416, 472, 507, 580, 632; infantum, 133; in Spain, 138; inoculations, 139, 334, 584; preventive measures, 1, 92; in Europe, 251; case of, 270; in Paris, 317; prophylaxis of, 325; morbus re. homicide and suicide, 509; imported by reapers, 711.
Chorea; case of, 601; treatment of, 633.
Chronic; eczema of, 257; nasal catarrh, 319; entero-colitis, treatment of, 360; endometritis, 350; diarrhœa, 417; bronchitis, hygiene of, 448; vesical catarrh, 450; alcoholism, 481; gastritis, 506; Bright's disease, 625.
Cholecystostomy; duodeno, 281; natural and ideal, 559.
Choroid, sarcoma of, 208.
Cigars, coca leaf, 483.
Cicatrization due to burn, 433.
Cirrhosis and perihepatitis, 719.
Clavicle; fracture of, 466; clean metal catheters, 676.
Climatic treatment; of pulmonary consumption, 735; of phthisis, 737.
Clinical notes on psoriasis, 302.
Clitordis epithelioma, 243.
Club system of medical attendance, 636.
Cobweb, tincture of, 740.
Coca leaf; therapeutical effects of, 415; cigars, 483; for alcohol habit, 510.
Cocaine; in ophthalmic surgery, 21; in opening buboes, 47; in acute affections, 105; in snuffles, 131; muriate of, 157; menstruum to dissolve, 161; for opium habit, 177; in operations for, 212; in ingrowing toe-nail, 217; use of, 219, 246; for healing of wounds, 301; failure of, 360; hydrochlorate of, 365; caution about, 413; in opium poisoning, 417; debauche, 484; pure, 487; in cracked nipples, 514; treatment with, 524, 534; in surgery, 543; litholapaxy with, 543; anæsthesia, 575, 606; in hay fever, 642; on stomach, effects of, 639; in gynecology, 649; for sea sickness, 675; in hydrocele, 705; poisoning, 708, 737; menstruum for, 708; in hyperæsthesia of, 709; in fractures and dislocation, 739; toxic action, 742.
Cod-liver oil emulsion, 450.
Coition, accidents during, 636.
Coitus; serious accidents during, 703; rupture of male urethra during, 707.
Cold bandaging of leg, 739.
Colic; biliary treatment of, 21; flatulent, in horses, 362.
Collodion for psoriasis, 512.
Colors on vision, 710.
Comma bacillus, the Koch, 513.
Complete absence of urethra, 379.
Composition on boils, 677.
Compound; dislocation of ankle, 404; fracture of humerus, 466; of astragalus, 467; epiphysial diastasis, 730.
Compression; and concussion, 404; treatment of hiccough by, 417; in common carotid, 475.
Conception without menstrual flow, 159.
Concussion; and compression, 404; of brain, 485.
Congenital; malformations of, 393; deformity, 482; dislocation and fracture of atlas, 633.
Congress; about the international, 573, 733; preliminary organization of, 742.
Conjunctiva; action of calomel on, 162; gumma of, 675.
Conservative ovariotomy, 190.
Constrictor loop and knot, 588.
Consumption; pulmonary, high altitudes on, 44; alcoholic, in Belgium, 223; prevention of, 700; treatment of pulmonary, 735.
Consumptives, forcible alimentation of, 668.
Contract services, 276.
Contraction of flexors of leg, 464.
Contusion; of arm, 466; of liver, 575.
Convalescence, typhoid, foot, pain in 706.
Convulsions; puerperal, without albuminuria, 216; during pregnancy, 237.
Copper oleate in tinea capitis, 154.
Cord; spinal, diseases of, 118; umbilical, traction on, 246; ligating, 260; navel, 330; hemorhage from, 331.
Corn, treatment of, 641.
Cornea; perforation of, 321; inflammation of, 555.
Corpse not property, 418.
Corpus spongiosum, rupture of, 707.
Corrosive sublimate; toxic enteritis due to, 359; a surgical dressing, 605; peculiar effect of, 752.
Corsets, 369; compression from, 485.
Coryza, acute; treatment of, 150; atropia in, 738, 753.
Cosmophobia, 484.
Cotton-reel in vagina, 710.
Cough; night, in children, 360; whooping, vaccination for, 609.
Coughs, wisdom about, 609.
Courtship, floral, in Japan, 613.
Cow-boy's bill of fare, 278.
Cracked nipples, cocaine in, 514.
Cramp, writer's, 209.

Insensible man, how to carry, 679.
Insensibility of decapitated heads, 550.
Insomnia; alcoholic, pilocarpine in, 482; produced by chloroform, 706; cold bandaging of leg in, 739.
Instrument, a new, for hearing, 419.
Interesting case, 710; for diagnosis, 471; of pneumothorax, 478; of monomania, 503.
Intermittent albuminuria in, 236.
Internal disinfectant; borax, 547.
International; Sanitary Conference, 25; Medical Congress, 247, 271, 335, 517, 733; preliminary organization of, 742.
Intestinal; stricture, 124; obstruction, 329, 705; treatment of, 415.
Intestines; gunshot wounds of, 492, 498; wound of, 514.
Intra-; pulmonary injections, 78, 705; cranial syphilis, 235; cranial cephalhæmatoma, 715; capsular fracture of femur, 720.
Intravenous injection of milk, 47.
Intra uterine erysipelas communicable? 328.
Intubation of larynx, 499.
Inutility of alcohol, 107.
Investigation, collective, 27.
Inveterate ozæna, 257.
Iodic purpura, 663.
Iodide; of potassium in common carotid, 475; huge dose of, 515; methyl, a vesicant, 671.
Iodine, tincture, in diphtheria, 416.
Irritation; spinal, treatment of, 72; urethral, 306, 672.
Irritability, vesical, 640.
Iris, inflammation of, 555.
Iritis, syphilitic, 257.
Irregular sexual development, 241.
Ischuria, hysterical, 469.

Jaborandi in erysipelas, 431, 676.
Jaw, lower, disarticulaton of, 593.
Jaundice from arsenical wall-papers, 447.
Jequirity in granular lids, 676.
Joint; diagnosis of fractures near, 479; artificial, 593.
Jugular vein, external venesection of, 664.

Keloid, conditions, which precede, 155.

Kidney, granular, 263.
Kidneys; surgery of, 54; primary tuberculosis of, 123.
Kill, hard to, 331.
Killing a woman, case of, 286.
Kissing, medical reflections on, 516.
Knee; anchylosis of, 432; arthritis of, 432; effusion around, 463; carcinoma of, 497.
Knife, cure of carbuncle without, 635.
Koch; testimonial to, 453; comma bacillus, 513.
Krao, 215.

Labor; complicated with, 329; complicated by, 360; at seventh month, 387; results of prolonged, 533; normal anæsthetics in, 546; premature, induction by electricity, 738.
Laboratories for State Boards of Health, 420.
Lacerated; perineum, 369; wounds, a dressing for, 417; wound of scrotum, 465; meningeal artery, treatment of, 599.
Laceration of cervix uteri, 263, 496.
Lacerations, detecting of, 380.
Lactart, 455.
Lacteal secretion, control of, 183.
Lancets, vaccine disinfection of, 247.
Laparotomy; operation of, 232; in gun-shot wound, 492, 498.
Laryngeal hemorrhage, 191.
Larynx; excision of, 247; lupus of, 379; stenosis of, 432; intubation of, 499; and trachea, 564; lupus involving, 726.
Latent vesical calculus, 184.
Law and professional evidence, 711.
Laws; of maternity, 297, 333, 417; medical, of Indiana, 604.
Lay advice to doctors, 647.
Lead-poisoning, 178; at sea, 582.
Leg; contraction of flexors of, 464; angeio-lencitis, 466; ulcers, 562; cold bandaging of, 739.
Lemons in Bright's disease, 21.
Leprosy, treatment of, 467.
Letter from Berlin, 643.
Leucitis, angeio-, of leg, 466.
Leucoplakia, buccalis, 356.
Leukæmia, lymphatic, in childhood, 617, 627.
Licenses to practice medicine in Japan, 388.
Lichen; treatment of, 192; sulpho-carbolate of soda in, 608.
Lids, granular, jequirity in, 676.
Liebreich treatment of syphilis, 480.
Life of Dr. J. L. Little, 627.
Lifeless, Paris Morgue, 223.
Ligament; inflammation of, 532; suppurating cyst of, 606.
Ligating umbilical cord, 260.
Ligaments, round, shortening of, 681.
Ligature, elastic, 451.
Light in front of the horse, 360.
Lightning; stroke, 385; on paralyzed woman, effect of, 637.
Lip, epithelioma of, 465, 531.
Litholapaxy, 563; with cocaine, 543.
Lithotomy, nephro- and nephrotomy, 706.
Liver; movable, in women, 525; distoma hepaticum on, 563; probable contusion of, 575; multiple abscess of, 697.
Living with a bullet in her brain, 754.
Localization, cerebral, 126.
Locomotor; ataxia, rare symptoms of, 546; hemiataxia, 664.
London hospital scandal, 710.
Longevity and riches, 518.
Lunacy in Paris, 582.
Lunatics, farm for, 276.
Luncheon habits of prominent men, 387.
Lungs, no air, could child have lived? 240.
Lupus vulgaris; relations of, 304; treatment of, 304, 608; of larynx, 379; involving the larynx, 726.
Luxations; of humerus, reduction of, 507; recurring, 735.
Lymphatic leukæmia in childhood, 617, 627.
Lymphoma, removal from, 66.

Machinery, scalped by, 647.
Macular or pigmentary syphilide, 673.
Maggots in ear, 475, 482, 613.
Malaria, relations of forests to, 484.
Malarial; fever, pathology of, 191; strychnia in, 219, 483; physiognomy of, 371; arsenic in, 607; affections, treatment of, 411; puerperal fever, treatment of, 514; sources of, 665.
Male; hysteria in, 160; sex, disease peculiar to, 230; urethra, congenital deformity of, 482; urethra, rupture of, 707.
Malformations, congenital, of heart, 393.
Malleus, external, inflammation of, 548.
Malignant; bilious fever, 133; pustule, recovery from, 190; scarlet fever, 744.
Mammary abscess, 688.
Man; after syphilis, sterility in, 153; young, senile change in, 409; insensible, how to carry, 679.
Maniacal excitement, treatment of, 406.
Management of pregnancy, 386.
Mania, the disinfecting, 680.

Parasiticides, treatment of lupus by, 304, 608.
Paresis, 433.
Paris, erysipelas in, 216.
Parturifacient, mistletoe as, 731.
Parturition; bacteria in, 34; shock and nervous influence in, 507.
Parovarian cysts, 373.
Pasteur's; inoculation for hydrophobia, 581; cases sent to, 744; inoculations for rabies, 718; patients, 750.
Patella, fractures of, 502.
Patent medicine paradise, 516.
Pathogenic germs in healthy blood, 513.
Pathological results of mimicking passion, 454.
Pathology; Dutch account of, 111; of malarial fever, 191; in Egypt, 335; of tenesmus of rectum, 468; of hemianopsia, 650.
Payment of medical men by results, 421, 479.
Peculiar case, 312.
Pelvic; cellulitis, in child, 132; hæmatocele galvano puncture in, 674; injuries in women, medico-legal bearing of, 737; hæmatocele, 740.
Pelvis; fracture of, 68; unilateral deformity of, 529.
Pencil in bladder, 416.
Penitentiary food, 387.
Pennsylvania; State Board of Health, 82; hospital, items of interest about, 755; University of, 755.
People, an out-door, 223.

Perforating ulcer of bladder, 183.
Perforation of cornea, 321.
Pericardial effusions, paracentesis in, 450.
Pericardium, topographical anatomy of, 35.
Perihepatitis, cirrhosis and, 719.
Perinephritic abscess, 300.
Perineorrhaphy, catalepsy cured by, 703.
Perineum; ruptured, 260, 688; lacerated, 369; protection of, 620.
Periosteum grafting, 569.
Peritonitis; fatal, 46; following typhoid fever, 77; ovarian cystoma with, 346; infectious, in virgins, 385.
Perityphilitis and typhilitis, 491.
Permanganate of potash baths, 47.
Peroxide of hydrogen a beer preservative, 549.
Phimosis, fatal cystitis due to, 665.
Phlebitis, 64; cause of, 161.
Phlegmasia alba dolens, 346.
Photography, microbic, 251.
Phthisical farm laborers, 55.
Phthisis; glycosuria in, 46; strychnine in, 111; heredity of, 358; antipyrin in, 575; inhalations in, 672; climatic treatment of, 737.
Physical; organism, diagnosticator of, 505; diagnosis, errors in, 556.
Physicians; are treated in Spain, 361; hospital duty of, 383; Clinical Record, a gift, 753.
Physiognomy of disease, 371.
Physiological; action of hydrochlorate of cocaine, 365; basis of diabetes mellitus, 377; effects of coca, 415.
Pianists, digital tenotomy in, 191.
Pigmentary or macular syphilide, 673.
Pill, how to take, 108, 162, 193, 302.
Pilocarpine; in loss of hearing, 96; injections of, 237; in croup, 312; in tooth-ache, 449; in alcoholic insomnia, 482; in puerperal eclampsia, 661.
Pin, swallowing a, 547,
Placenta, retention of, 244, 457.
Placenta prævia; treatment of, 482; case of, 718.
Plants; for window culture, 362; poisonous, 419.
Platypodia, 464.
Flatulant colic in horses, 362.
Plebitis, 64.
Pleural effusion, case of, 472.
Plum-stone in trachea, 575.
Pneumo-thorax, 403; interesting case of, 479.
Pneumonia, 719; morbid anatomy of, 122; case of, 207; broncho-, 321; gouty, 439; treatment of, 450, 664; acute croupous, 504; infantile cerebral, 508; reduction of temperature in, 740.
Pneumogastric nerves, compression of, 417.
Poisoning; septic, 45; from chloroform, 130; by tincture of digitalis, 159; lead, 178; aconite, 192; by sausages, 307; by hyoscyamin, 368; opium, cocaine in, 417; by oil of tansy, 417; with rhus toxicodendron, 417; lead, at sea, 582; opium, 609; cocaine, 708, 737.
Poisonous; doses, 79; qualities of sulphurous acid, 187; plants, 419; effect of urine, 446; is extract of beef? 541.
Police surgeons, 270.
Popliteal aneurism, 173.
Polycystic ovarian tumor, 347.
Polypus, uterine fibroid, 374.
Polyuria, 345.
Popliteal; aneurism, simulating sarcoma, 106; abscess, 433.
Populations, nomadic, health of, 194.
Port-wine mark, treatment of, 304.
Possible mistakes, 214.
Postage-stamps, do not lick, 455.
Post-mortem albuminuria, 731.
Post-partum; hemorrhage, 257; cervix uteri, 380.
Potash baths, permanganate of, 47.
Potassium iodide, huge dose of, 515.
Pott's disease, paralysis from, 595.
Power, the waking, 82.
Practice; rare cases in, 396, 429.
Practitioners, registration of, 549.
Precipitation, sewage, new process for, 676.
Pregnancy; extra-uterine, 38; mole, 42; convulsions during, 237; complicated with, 329; management of, 386; suspected, 496; after double ovariotomy, 515; oxalate of cerium in vomiting of, 545; unsuspected, 574; vomiting in, 630; hygiene of, 702.
Prehistoric dentistry, 485.
Premature; rearing, infants, 385; birth, 420; labor, induction by electricity, 738.
Prescriptions; renewing, 251; write legible, 486.
Presentation, brow, spontaneous delivery of, 696.
Prevention; of insanity, 381; of bad teeth, 613; of consumption, 700; of septicæmia, 709.
Procidentia uteri, 369.
Production of phantom tumor, 106.
Profession, medical, its relation to the public, 398.
Professional evidence, law and, 711.
Professional, too, 550.
Progenitor to progeny, transmission from, 380.
Prognosis in Bright's disease, 727.
Progress in medicine, 558.
Progressive locomotor hemiataxia, 664.
Prolapsed uterus, labor with, 387.
Prolapsus uteri, 350.
Prophylaxis; of cholera, 325; of calculus, 708.
Prostate, enlarged, 405.
Prostatic, massage in, 328.
Prostatistis, 230.
Protection of perineum, 620.
Pseudo-hypertrophic paralysis, 595.
Psoriasis; clinical notes, 302; pyrogallic acid and collodion for, 512.
Psychical research, 306.
Psychological aspect of suicide, 601.
Puberty in Finland, age of, 301.
Puerperal; convulsions without albuminuria, 216; state, symptoms in, 473; fever, treatment of, 514; eclampsia, pilocarpine in, 661; diphtheria, 740.
Pulmonary; consumption, high altitudes upon, 44; intra-, injections, 78; phthisis, nutrition and growth in connection, 540; syphilis, 626.
Pulse; character of, 285; in acute nephritis, 329.
Puncture, galvano, in pelvic hæmatocele, 674; intra-, injections, 705; consumption, treatment of, 735.
Purification; of drinking water, 55; of waste waters, 455.
Purpura iodic, 663.
Pustule, malignant, recovery from, 190.
Pyelitis, idiopathic, 370.
Pylorectomy, partial, 192.
Pyloric obstruction, 634.
Pyonephritis and hydronephrosis, 632.
Pyrexia, neurotic, 300.
Pyridine, 189; notes on, 656.
Pyrogallic acid for psoriasis, 512.

Pyrophobia, case of, 694.

Quillaja bark in emphysema, 707.
Quinia, bihydrobromate of, 477.
Quinine; in pneumonia, 664; and typhoid fever, 695.
Quinsy, treatment of, 515.

Rabbit's eye, transplantation of, 384.
Rabies, Pasteur's inoculations for, 710.
Rachitis, paralysis from, 595.
Railroad, contract for services with, 276.
Ranula, location and treatment of, 750.
Rape, alleged, by a boy, 481.
Rare cases in practice, 396, 429.
Raynaud's disease, 99.
Razors to sharpen, 518.
Ready for business, 615.
Rearing premature infants, 385.
Recovery of sight after blindness, 98.
Rectal cancer, 397.
Recto-labial or vulvular fistulæ; their causes and treatment, 753.
Recto-labial or vulvular fistulæ, 738.
Rectum; stricture of, 16; hair-pin in, 232; undeveloped, in infant, 430; imperforated, 434; tenesmus of, 468.
Recurrent vesicular eruption, 447.
Recurring luxations, 735.
Reducing luxations of humerus, 507.
Reduction; false, of hernia, 70; of shoulder dislocation, 564; of temperature in pneumonia, 740.
Reflexes, observations on the cutaneous and deep, 247.
Registration of practitioners, 549.
Regurgitation, mitral, 8.
Re-infection, syphilitic, 332.
Relations; of forests to malaria, 484; of development to use, 751.
Remarkable case, 238.
Remedy; for hay fever, 610; for galvanic taste, 708.
Removal; of lymphoma from neck, 66; of needle, 219; of whole tongue, 292; of deep cervical glands, 594; of superior maxilla, 594; of ovaries, 596; of entire tibia, 698.
Renal calculus, 631.
Renewing prescriptions, 251.
Repairing of hypodermic syringes, 645.
Requirements of sick-room and nursery, 300.
Research, psychical, 306.
Resection of bone after burn, 730.
Resorcin; antidote for, 449; in diarrhœa, 673.
Restoration of respiration under chloroform, 440.
Respiration; under chloroform, restoration of, 440; on artificial, in sunstroke, 575.
Respiratory, upper, passages, cocaine in, 105.
Retention; of placenta, 244; of urine, 328; of placenta, 457; aspiration of bladder, for, 675.
Retraction of testicle, 465.
Retro-uterine hæmatocele, 228.
Retroversion of uterus, 66, 494.

Sexual, irregular, development, 241.
Sharpen razors, 518.
Shock, influence in parturition, 507.
Shortening of round ligaments, 681.
Shoulder dislocation, reduction of, 564.
Sick; feeding, 272; diet for, 273; room, requirements of, 300.
Sickness, sea-, cocaine for, 675.
Sight, tobacco injure? 263, 416.
Silk-worm, gut suture, 483.
Simulo in epilepsy, 80.
Singers, voice in, 61.
Singular case, 217.
Sitiophobia among insane, 359.
Skeletons, curious collection of, 363.
Skin; multiple sarcoma of, 69; diseases, to marriage, relations of, 151, 536; diseases, boroglyceride in, 514; grafting, 565.
Skull; fracture of, 435, 466, 548, 576; very tough, 421.
Sleeping apartments, disinfection of, 388.
Sloughing, scrotitis with, 548.
Small-pox, 334; disinfection after, 387; vaccination, a preventive of, 565.
Smoking; in bed, 336; Huxley on, 362.
Snake-bite, treatment of, 547.
Snuffles, 561; cocaine in, 131.
Soda, sulpho carbolate, in lichen, 608.
Sodæ, chlorate liquor, in enteric fever, 641.
Sodium; ethylate, in nævus, 513; nitrite, in gout epilepsy, 675.
Solution, atropo-morphia, 505.
Special; features in Reporter, 413; *vs.* general study in medicine, 436.
Special Reports—
Ophthalmology, 21, 47.
Progress of otology, 577, 610.
Spleen, rupture of, 465.
Spasmodic paralysis in children, 594.
Specific ulcerations, 435.
Spermatorrhœa, 257; salix nigra in, 547.
Spinal; irritation, treatment of, 72; cord, dis-

eases of, 118; sclerosis of, 591; cerebro-, fever, 188; myelitis, acute, idiopathic, 474.
Spine, dislocation and fracture of, 243.
Splint; new bunion, 244; a new hip, 462.
Sponge; grafts for carbuncle, 329; tent in uterus, 570.
Sponging, cold, of chest, 504.
Spontaneous; rupture of membranes, 190; dry gangrene of toe, 467; delivery, 696.
Squint, operation for, 111.
Starvation and suspended animation, 159.
State Board of Health, 307, 606.
Stenosis; of larynx, 432; dysmenorrhœa due to, 547.
Sterility, 721; in man after] syphilis, 153; by vaginal secretion, 218.
Sternum, necrosis of, 465.
Stethoscope, new binaurial, 663.
Stomach; encephaloid disease of, 94; cancer of, 406; effects of cocaine on, 639; scirrhus of, 726.
Strangulated; hernia, 495; femoral hernia, 633; inguinal hernia, 729.
Strangulation, death by, 491, 726.
Strength, drugs deficient in, 222.
Stretching the supra-trochlear nerve, 674.
Stricture, 372; of rectum, 16; intestinal, 124; and cystitis, 372.
Stroke, lightning, effects of, 385.
Structure of derma, 305.
Strumous abscesses, 434.
Strychnia; in malarial fevers, 219, 483; in diphtheritic paralysis, 246.
Strychnine; in phthisis, 111; in delirium tremens, 672.
Styptic, antipyrin as, 477.
Subclavian, aneurism of, 466.
Subcutaneous injections of urea, 514.
Subnitrate of bismuth, a dressing, 514.
Sugar in exhaustion, 638.
Suicide; by bichloride solution, 358; psychological aspect of, 691.
Sulpho-carbolate of soda in lichen, 608.
Sulphurous acid, poisonous qualities of, 187.
Summer complaint, treatment of, 102.
Sunstroke; antipyrine in, 234; sequelæ of, 493; and heat exhaustion, 521, 534; artificial respiration in, 575.
Superstition, a queer, 485.
Suppression of urine, nephrotomy for, 736.
Suppurating cyst of broad ligament, 606.
Suppuration, rheumatism terminating in, 257.
Supra-; vaginal removal of uterus, 596; trochlear nerve, stretching the, 674; pubic aspiration of bladder, 675.
Surgeon General, annual report of, 734.
Surgeons, police, 270.
Surgery; abdominal, 13; ophthalmic, cocaine in, 21; antiseptic, 53; orthœpedic, 109; cerebral, 245; of tenesmus of rectum, 468; cocaine in, 543; abdominal, 624, 629.
Surgical; treatment of epilepsy, 69; of infants, 85, 113; cases, 430; of gall stones, 441; practice in Bellevue Hospital, 502; meteorology, 583; dressing, corrosive sublimate as, 605.
Suspected pregnancy, 496.
Suture, silk-worm gut, 483.
Swag-belly in women, 525.
Swalling; a nail, 296; scarf-pin, 547.
Swollen testicle, 466.
Symmetrical gangrene of finger, 671.
Symptoms, rare, of locomotor ataxia, 546.
Syphilide, macular or pigmentary, 673.
Syphilis; transmission of, 79; sterility in man, 153; case of, 181; intra-cranial, 335; albuminuria of, 267; hereditary, 432; Liebreich's treatment of, 480; treatment of, 436, 511; in Cape Colony, 545; pulmonary, 626; warning about, 669.
Syphilitic; hepatitis, 101; infection, 188; iritis, 257; re-infection, 332, 340; aphasia, 333; abscess of tibia, 564; foci, foundlings, as, 615.
Syringe, hypodermic, repairing of, 645.
Systematic examination of wet-nurses, 79.

Tabes dorsalis, 107.
Tænia echinococcus, 563.
Tallow-rendering a nuisance, 335.
Tænia, 337.
Tannate of cannabine, 21.
Tænia, medio-canellata, 563.
Tansy oil, poisoning by, 417.
Taste, galvanic, remedy for, 708.
Teeth; zymotic diseases on, 415; heredity and development of, 449; bad, prevention of, 613; artificial, may damage, 678.
Telegraph, life saved by, 755.
Telephone, a novel, 389.
Temperature; on muscles at rest, influence of, 600; in pneumonia, reduction of, 740.
Tenesmus of rectum, 468.
Tenotomy, digital, in pianists, 191.
Terpine and terpinol, 218.
Terpinol and terpine, 218.
Testicle; hæmatocele of, 406; retraction of, 465; swollen, 466; tumor of, 662.
Testicles; removal of, 19; new, 641.
Testimonial to Professor Koch, 453.
Testing for albumen, 274.
Tests for albumen, 482.
Tetanoid epilepsy, 494.
Tetanus, 652; idiopathic, 76; urari in, 161; typhoid fever with, 203; traumatic treatment of, 694.
Therapeutic; knife, antiphlogistic touch of, 574; value of arsenic, 567; agent, electricity as, 628.
Therapeutical; inventions, 83; hints, 328; effects of coca, 415.
Thigh, fracture of, 403.
Thoracentesis and paracentesis, 733.
Thorax-pneumo, 403.
Throat, foreign bodies in, 673.
Thrombosis, carbonate of ammonia in, 442.
Thyroid gland, function of, 187.
Tibia; syphilitic abscess and necrosis of, 564; necrosed, 655; removal of, 698.
Tibiæ, both, caries of, 121.
Tincture; of digitalis, poisoned by, 159; of iodine in diphtheria, 416; of cobweb, 740.
Tinea; capitis, oleate of copper in, 154; favosa, mycological studies in, 304; tonsurans, treatment of, 440.
Tissue, development of, 305.
Toads, a tonic, 518.
Tobacco, injure sight? 263, 416.
Toe; nail, ingrowing, cocaine in, 217; ingrowing, painless removal of, 641; spontaneous dry gangrene of, 467; amputation of, 532.
Tongue; ablation of half of, 120; removal of,

292; man's natural, 451; biting of, 455; glycerine in dryness of, 609.
Tonic, toads as, 518.
Tonsilitis, 367.
Tonsurans, tinea, treatment of, 440.
Toothache, pilocarpine in, 449.
Toxic; enteritis, 359; action of cocaine, 742.
Toxicodendron, rhus, poisoning with, 417.
Trachea; artificial teeth in, 67; and larynx, 564; plum stone in, 575.
Traction; on umbilical cord, 246; conduits, 279.
Transfixion of scrotum, 704.
Transplantation of rabbit's eye, 384.
Transmission; of syphilis, prevention of, 79; of alcoholic diseases, 108; from progenitor to progeny, 380; of infectious diseases, 584.
Traumatic; epilepsy, 69; origin, possibly, 131; erysipelas at ankle joint, 429; tetanus, treatment of, 694.
Treatment; of biliary colic, 21; of cholera, 42, 274, 416, 472, 507, 580, 632; of gastric affections, 45; surgical, of epilepsy, 69; of multiple sarcoma of skin, 69; of empyema, 72; of spinal irritation, 72; surgical, of infants, 85, 113; of dysentery and summer complaint, 102; of phthisis, 111; of neuralgia, 131; of acute coryza, 150; of cystic tumors, 169; of melancholia, 174; of lichen, 192; of writer's cramp, 209; of gout, 211; of nephritis, 218; of whooping cough, 219; of convulsions during pregnancy, 237; of gall-stone, 247, 441; of syphilis, 267, 480; of tumors of bladder, 272; of infantile eczema, 291; of venereal diseases, 301; of port wine mark, 304; of lupus, 304, 608; of indigestion, 320; of acute diarrhœa, 329; of chronic entero-colitis, 360; of poisoning by hyoscyamine, 368; of cephalalgia, 375; of acute rheumatism, 378, 438, 671, 676; of maniacal excitement, 406; of rachitis, 409; of malarial affections, 411; of intestinal obstruction, 415; of cystitis, 416; of hiccough, 417; of syphilis, 446, 511; of tinea tonsurans, 440; of pneumonia, 450, 664; of leprosy, 467; of typhoid fever, 470, 530; of hyperidrosis, 474; of wounds of fingers, 478; of placenta prævia, 482; of fractures of patella, 502; of dyspepsia, 506; of acute croupous pneumonia, 504; of chronic gastritis, 506; notes, 506; of nævus, 513; of puerperal malarial fever, 514; of quinsy, 515; of rose cold and hay fever, 524, 534; of masturbation, 547; of snake bite, 547; by Oertel's method, 585; of cerebral palsies, 596; of lacerated meningeal artery, 599; of earache, 609; of chorea, 633; of hysteria, 638; of nervous complications of typhoid fever, 640; of rebellious corn, 641; of frost-bitten fingers, 642; of obesity, 646; of disease in India, 646; of traumatic tetanus, 694; of expulsive gingivitis and osteo-periostitis, 703; of catalepsy, 703; of placenta prævia, 718; of adherent secundines, 722; of deformities after burn, 730; climatic, of phthisis, 737; of recto-labial or vulvular fistulæ, 738; of dysentery, 739; of pelvic hæmatocele, 740; of pulmonary consumption, 735.
Tremens, delirium, strychnine in, 672.
Trigeminal neuralgia, nitro-glycerine in, 238.
Trigger finger, 514.
Triplets, case of, 569.
Tubercle, direct inoculation of human being by, 104.
Tubercle, case of, 302.
Tubercular meningitis, 433; nephritis, 609.
Tuberculosis; meningitis, 57; primary of kidneys, 123; lupus vulgaris to, 304; of retro-peritoneal glands, 726.
Tumor; phantom, production of, 106; removal of, 206; polycystic ovarian, 347; sarcomatous of antrum, 404; fibroid, removal of, 596; of testicle, 662; cystic, of ovary, 724.
Tumors; cystic of jaw, 169; of bladder, 272.
Twelve old-fashioned beverages, 451.
Twin in bad company, 25.
Tying the navel cord, 330.
Tylosis of hands, 305.
Tympani membrana, rupture of, 654, 692.
Typhlitis and perityphlitis, 491.
Typhoid fever, 401, 454, 608; periostitis following, 77; with tetanus, 293; physiognomy of, 371; ox-oil in, 470; treatment of, 530; case of, 561; modified form of, 634; nervous complications of, 640; fever and quinine, 695; convalescence, foot-pain in, 706; gangrene and arteritis, 707.
Typhus, epidemic of, 389.

Ulcer, perforating of bladder, 183.
Ulcers; leg, 562; should old be cured? 663.
Ulcerative syphilide, 302.
Ulcerations, specific, 435.
Umbilical cord; hemorrhage from, 162; traction on, 246; ligating, 260; hemorrhage, 331; hernia, 561.
Undeveloped rectum in, 430.
Undilated os, anus mistaken for, 517.
Unfiltered water and disease, 711.
Unhealthy meat, 335.
Unilateral deformity of pelvis, 529.
Urates, the, 5.
Urari in tetanus, 161.
Urea, subcutaneous injections of, 514.
Urethrocele, case of, 265.
Urethra; rupture of, 245; complete absence of, 379; male, congenital deformity of, 482; male, rupture of, 707.
Urethral irritation in the male, 306, 672.
Uric acid, an eliminator of, 211.
Urie, blood in, 576.
Urine; hydatids passed with, 231; blood in, 263; after nephrectomy, 300; retention of, 328; poisonous effect of, 446; nephrotomy for total suppression of, 736.
Urticaria, salicylic acid in, 609.
Uteri; cervix, laceration of, 263; post-partum, 380; laceration of, 496; cancerous, 506; prolapsus, 350; procidentia, 369.
Uterine; extra, gestation, 228; appendages, removal of, 266; dilator, 372; fibroid polypus, 374; diseases, hydrastis in, 675.
Utero-gestation, vertigo from, 457.
Uterus; hyperæsthetic condition of, 24; sarcomatous gestation in, 38; retroversion of, 66; carcinoma of, 124; recovery from rupture of, 160; normal position of, 179; prolapsed labor with, 387; retroversion of, 494; sponge tent in, 570; supra-vaginal, removal of, 596; inner surface of, 600.

Vaccine; lancets, disinfection of, 247; Ferran's, 486; farms, State, 573.
Vaccination, 355; gangrene after, 245; riots in

Montreal, 388; in Canada, 420; riots, 446; a preventive of, 565; for whooping cough, 609.
Vagina, foreign bodies in, 29; cotton reel in, 710.
Vaginal; wall, posterior cyst of, 178; secretion, sterility from, 218; fistula, 219; injections, use of, 246; cyst, 309; injections, morphia habit by, 579.
Valvular disease of heart, 435.
Vegetarianism, 306.
Venereal diseases, treatment of, 301.
Venesection of external jugular vein, 664.
Ventilation; drain, danger from, 244; cellar, importance of, 679.
Vertebra, cervical fracture of, 463.
Vertigo produced by utero-gestation, 457.
Vesical; tenesmus, 132; calculus, latent, 184; explorations, 295; irritability, 640.
Vesicant, methyl iodide as, 671.
Vesicular eruption, recurrent, 447.
Vessel wounds, auscultation of, 410.
Veterinary hospital of university, 278.
Virgins, infectious peritonitis, 385.
Vision, effects of brightness and colors on, 710.
Vitiligo, 155.
Vivisection; bill, failure of, 186; in Austria, 453.
Voice in singers, 61.
Vomiting; oxalate of cerium in, 545; in pregnancy, 630.
Vulvular fistulæ or recto-labial, 738.

Waking power, 82.
Wall papers, arsenical, jaundice from, 447.
Water; drinking, purification of, 55; Blue Lick, in lichen, 192; supply, 278, 382; of ancient Roman cities, 248; is fattening, 383; mineral, of Peru, 454; Opperman's patent purification of, 455; a local anæsthetic, 515; unfiltered and disease, 711.
Watery discharge of dead subjects, 45.
Wells and bacteria, 196.
Wet nurses against, 644.
Whooping cough; treatment of, 219; vaccination for, 609.
Wills, ante-mortem, probate of, 276.
White lead paint for erysipelas, 449.
Wind-pipe, foreign body in, 642.
Wire suture; in fractures, 502; in Paris, 516.
Women; doctors in India, 277; gonorrhœa in, 467; movable liver in, 525; in medicine, 572; pelvic injuries in, 737; American, menstruation of, 740.
Wound; of diaphragm, 50; lacerated, of scrotum, 465; of intestines, 492, 498; of small intestines, 514; at base of brain, 534; bullet of, heart, 742.
Wounds; of eye-ball, 136; cocaine upon healing of, 301; auscultation of vessel, 410; lacerated, a dressing for, 417; of fingers, treatment of, 478; a dressing for, 514; incised, 676.
Write legible prescriptions, 486.
Writer's cramp, treatment of, 209.

Yellow fever; inoculations for, 583; researches on, 641.
Yellowstone Park a winter sanitarium, 83.
Yucca angustifolia, examination of, 301.

Zymotic diseases on teeth, effects of, 415.

LOCAL AND NATIONAL PREVENTIVE MEASURES AGAINST CHOLERA.*

BY EZRA M. HUNT, M. D.,
Of Trenton, N. J.

The April speech of Mr. Gladstone in Parliament has several sentences in it quite as applicable to our relation to cholera as it was to the relation of England to Russia. Let me, with very slight abbreviation, quote a few lines of his language.

"Let us consider," he says, "what is the present position, and what is the mode of conduct adapted to that position. It is not a case of attack. The question before us at this moment is a simple and very narrow one. What we present to you is a case for *preparation*. Is there or is there not any case for preparation? Look at the facts before us. Try them by that test and by no other. Enter only into that part of the case which is prudential. Upon that aspect of the case and that alone—we say it is a case for preparation. The facts within your knowledge are enough to make it your bounden duty to prepare."

It is, I presume, because of such sentiments and convictions, that this Society has this evening invited papers and discussions about Asiatic cholera.

It goes without the saying, that the first measure for preventing the spread of cholera is to prevent its arrival in the country. The best way of doing this is to prevent its setting sail, or so guard against it during the voyage of vessels from infected ports to this country, as that any risk therefrom shall be greatly diminished. For this purpose, the employment of competent medical officers, versed in all the details of inquiry and inspection at each hazardous port of departure, is a measure which should meet with the approval of all authorities.

Next to it is the securement of that kind of roll-call or sick-list inspection on the passage (not common at sea), which shall know of and attend to any case of sickness, and so prevent a spread of disease.

An extended system of such guarding and strict discipline and application of detail of method, followed by a quarantine system like that of the port of New York, faithfully carried out, is equal to the prevention of any case of cholera in this country, except by the rarest accident. It is at least the radical, and so much the most efficient way for reducing the possibility of the occurrence of Asiatic cholera in this country, that its advocacy on the part of all medical men and its methodical carrying out by the National government cannot be too urgently pressed as indispensable. I purposely pass this part of the subject with a brevity out of all proportion to its importance, because it does not need argument, but only statement and such application as can only be given to it by national activity and precision.

As, however, governments, like individuals, as to what is expedient to be done, often have more forethought than foreact, and more of afterthought than either, it is wise to consider what ought to

*Read before the Philadelphia County Medical Society, May 25, 1885.

be done by *us* beforehand, in the prospect of a possible or probable invasion.

I shall not occupy your valuable time by expanding what is now an axiom, that there is such a thing as local and individual susceptibility to the disease, which largely determines the places most affected, and the persons most likely to suffer. The susceptibility of locality is to be overcome by putting it, and keeping it, in the best hygienic condition—a direction no longer diffuse in its meaning. But as time and financial ability may not be equal to all the details of the service, chief attention must be directed to the removal of all accumulated filth, the more prompt and complete removal of all organic matter capable of undergoing decomposition, and such correction of all defects in house-drains or soil-pipes of any kind as will insure their essential completeness. Such measures taken beforehand are far more important than most that can be done in this line after the disease is present in a place, since there is a limit to the disturbance of accumulated filth at certain seasons, or in the actual presence of a deadly disease.

Next to this is the attention to water-supply. For although the system does seem to establish a certain kind of toleration of an imperfect water-supply under its usual use, to those accustomed to it, water containing decayed or decayable organic matter has seemed to afford *special carriage* for those diseases to which the mucous membrane of the digestive apparatus is susceptible.

While it is true, as Dr. Simon has put it, that "a single case of cholera may, *if local circumstances coöperate*, exert a terrible infective power on considerable masses of population," it is equally true, and has been verified in multitudes of instances, that a single case, or cases in a single house, if local circumstances do not coöperate, is not likely to have extension, if all proper methods to prevent the spread of the disease are used. We have the definite statement that in the epidemics of India something else besides arrival determined both the quality and quantity of the disease. In four late epidemics, 1877–8–9–80, there were 154,986 villages attacked. In 58,972 of these there was only one death, and in 20,596 only two deaths, and yet in these years the total mortality was 1,380,226.—(Surgeon-General John Murray.)

As to the individual, to a more limited and yet practicable degree it is possible for him to have a clearing up and conform himself to those hygienic conditions which are also well understood, and which include correct habits, good food and water, well-sustained nutrition, and a contented mind. And if for any reason he has not or cannot have these, inasmuch as susceptible localities and susceptible individuals, when kept together, are far more apt to show results injurious to the locality and deadly to the individual than either alone, if the individual cannot or will not be improved, he should at least make arrangements for sojourn in another place, where the hygienic conditions of his surroundings will compensate for the defect in himself. It is sometimes easier to remove susceptible individuals, and all individuals in fact, than it is to correct surroundings.

In view of any deadly disease, which, getting virulence from the combination of foul localities and foul persons, may and does become a pestilence, reaching out to those less susceptible, it is well for us to consider how far it is wise to be prepared with *refuge stations* for those whom it may become a public policy quickly to separate from all their surroundings.

The only other thing, perhaps, that just here we need to notice as to be done in advance, is that we should have very definitely agreed upon the course to be pursued as to any first cases that may occur. While this could hardly be expected of the local boards of smaller towns, it is due to the chief cities, and to the country, that the boards of great cities like this should have prepared and published their syllabus, both as a guide for others and that they may profit by suggestions made. The admirable extent to which this was done in Great Britain, summer before last, in apprehension of a possible visitation last summer, is in every way worthy of imitation. For the prompt and effective dealing with the first case is far less likely to happen than with the hundredth case, and yet no case in the hundred begins to have the importance attaching to its management that the first one has. And if on the first day of June a case of cholera should occur in this city, the Board of Health ought now to be able to tell us that, with no loss of time more than if it were an alarm of fire, they would dispatch a physician and a nurse for the patient, a medical man to look after the rest of the household, and a sanitary inspector to be in charge of the building, and to do whatever the board had directed.

We now come to a consideration of the means to be used, when cholera has actually come to be in a city.

The mode of its management will very largely depend upon the views we have as to its method

of spreading. Until we determine with some definiteness whether it is, or in what sense it is, a contagious or transmissible disease, we are not prepared to adopt methods suited to its limitation. If we hold to the view that it is not a disease which one person can acquire by contact with another; that even the secretions can give it only when not quickly removed, or when they affect water or food; that it is never simply air-breathed; that there is no risk except from garments to which cling particles of anal or oral discharges, our action will be different from that needed if it is transmissible in a more general sense. We believe there are at least two reasons why, in practical attempts at prevention, we are not to stand upon nice opinions as to contagion or infection, but to speak of it and deal with it as communicable. While the view is entertained that the vomited or voided discharges are media of the contagion, we know of no high authority who says positively that they are the only media. The language of Simon and Buchanan is, "Probably, under ordinary circumstances, the patient has no power of infecting other persons, except by means of these discharges" (from the stomach and bowels). The language of Chaumont is, "A majority of those in this country hold that there is a disease-poison, but that it *chiefly* is to be found in the material ejected from the body of the sick, in the rice-water stools, and the vomit of the sick," etc.

We have looked in vain for any one who absolutely excludes air as a possible medium. Where the contagion is said to attach to fomites, and to relate to things rather than persons, we have to remember that, in a sense, the skin may be a thing as much as the light flannel which is the covering next to it, and so such a distinction may be without a difference, and the person be the real carrier.

While we believe it not to be communicable to the extent or degree, or in the sense, that some other diseases are, and that, with proper precautions, those who know what to do and how to do it will not contract the disease, we nevertheless believe that arrangements for dealing with it must assume its communicability. This being the case, *isolation* of the sick from the well should be at the basis of all skilled management. Because in any method of attempting to secure the isolation by the removal of the person from the place where the sickness occurs, there is involved exposure and congregation instead of separation, the rule should be to remove the well from the room, or—better still—from the house. *Leave the sick, remove the well*, is the rule which must make the first deep impression on the mind of the sanitary superintendent; but with the recognition that the rule is only a standard from which there must necessarily be many deviations. These will be recognized and arranged for where it is totally impracticable to apply the rule.

If to-day a person is taken sick with cholera in any house, and is at once provided with proper medical and nurse attendance; another medical attendant placed in charge of all others in the same house, to watch and meet any case of diarrhœa, and a skilled sanitary inspector is placed in charge of his department to furnish and apply whatever is needed in his line, as to inspection and disinfection, most of the first cases will have no following. If they do, then removal of all well persons from the building, and sometimes from adjacent ones, under direction and inspection, both in the act of removal and afterward, is the feasible plan. Where the case occurs at some public place, where removal is necessary, the galvanized-iron or other metal ambulance should be used under direction of the sanitary inspector. It should reach a case just as at present the hospital ambulance reaches a case in a city, the removal not being attempted in an unskilled way by others, and the place to which removal is made being duly chosen beforehand. Great Britain, without its quarantine, has often illustrated, as it did last summer in Liverpool, how persons from infected ships, after proper cleansing of vessel and attention to baggage, may come into a city under surveillance, so that a case of choleraic diarrhœa or cramps, as occurred in that instance, is speedily met, and no death or focus of contagion results. Over and over again, cities under well-governed sanitary police are now showing that not only cholera, but yellow fever, diphtheria, typhus, scarlet fever, etc., ought always to be met in just this prompt way. The attendance of a proper nurse and physician to such persons being secured, and a medical watcher for all the rest of the family, or those closely adjacent, the sanitary inspector and his aids cannot be too busy in putting that house, and the street, and the neighboring premises, in the very best condition. It must be fully understood beforehand just what disinfectants will be used, and how house-cleaning shall be done, and to what extent any accumulated foul material shall be either covered or removed. The skilled disinfecting corps of New York city so well understand this as to need no directions, and a full outline of their plan is easily secured.

In addition to this thorough attention to all surroundings, and this circumspection over individuals, it is known that I hold to the view that in all these diseases, introduced from without by a specific contagion, we can do much by quick prophylaxis for the individuals exposed or in the same house. Potassium chloride, tinc. ferri chloridi, quinine, and some other sterilizing substances, maintained as present in the blood, as they may be by frequent administration of small quantities, and topically on the throat and exposed mucous surfaces, have for me saved many a family from diphtheria and scarlet fever, and will modify the susceptibility of most of those exposed. As I have before sufficiently insisted upon this view, and as it is gaining strong support from others, I do not need to enlarge upon it here. It is probably as possible to put an individual in a temporary state of prophylaxis as it is for a time at least to change the susceptibility of a locality.

We have thus far supposed cases where cholera has occurred only to a circumscribed degree, which, with proper precautions, will be the chief actual way in which we will have to meet the disease if it come. But what shall be done if, as does occasionally occur, it all at once appears in a city, and, owing to unusual favoring conditions of atmosphere and circumstances, as at Niagara Falls (1854),* it shows great spreading tendency. Here, as before, we believe most depends upon a corresponding rapidity of a well-organized corps of physicians, nurses, and sanitary police, to reach each new case, and each case of prodromal diarrhœa, immediately.

This means prompt isolation of the *well*, house-to-house inspection, treatment, and disinfection. The removal, under observation, of all the unaffected people of a block or neighborhood might become the wisest measure. On the other hand, occasional, but exceptional, instances do occur, where it is better to remove the sick, and leave the well under the closest observation, and their homes under the most active sanitary administration. The experience of England in 1866, and of New York city, go very far toward showing that organization and discipline are the best combatants of the disease. In re-examining with care the testimonies in India, Great Britain, and in the United States and Canada, as also the Western experience of 1873, we find that the fact and the controllability of an initial stage is the one hopeful element, which must be matched by such readiness of administration, and such close inspection, *as will not let any case of diarrhœa occur without attention.*

*2 Vol., A. P. H. Assoc., S. B. Hunt, M. D.

We have the recent statement of Surgeon-General Murray, that "the practice in India is the general distribution of remedies to meet any tendency to flux. They are distributed through the police, with instructions for their use, and an earnest command for their early application. The success of these measures is reported by all the civil authorities as most satisfactory, whilst any want of success is equally attributed to delay in their use till the disease had advanced to the stage of collapse."

With such methods and precautions as we have noticed, with preventive cleanliness, thorough isolation and disinfection, attention to first symptoms and first localities and all that inhabit them and the quick disposal of all excreta and all soiled clothing, and the avoidance of eating and drinking in a house in which there is cholera, we believe we have reason to feel that we are fully equipped, as never before, to contend with this foreign foe.

Whatever else is obscure, we have settled that the foe has no spontaneous outbreak within the system, but that it goes in through the throat; that its critical act is the very rapid multiplication of infinitesimal life, the initial stage starting in the stomach, and the profoundest effect being upon the nervous centres, and in the rapid reduction of the watery element of the blood and tissues. Our work is rapid counteraction, viz.: such equivalent to spraying as will protect the nose, mouth, and throat, as really as we now protect a wounded surface; such anti-culture condition of the stomach as will do just the opposite for bacilli to what a culture-field does for them; such stimulation of the nervous system, and such introduction of fluids as will suspend the devitalization which is going on and the mechanical phenomena with which it is accompanied. Talk as we do about our empirical treatment of Asiatic cholera, no one can compare the treatment in Asia, or Europe, or America, without seeing how uniform is the agreement as to checking early the diarrhœa, and as to the use of such internal means as will insure quick response from the stomach and the nervous system. The Asiatic pill of opium, assafœtida, and black pepper, has its counterpart in almost every combination used elsewhere. The patient and the physician who begin at the very start, and contend against both exposure and symptoms, in this antagonistic line, will seldom be baffled. With a fair chance, the medical profession is ready and equipped to prevent epidemics, as never before, and to satisfy all, except that too great multitude which is willing

to neglect *slight* prevention and first symptoms, and then, when all the peril is upon them, wonder why the doctors cannot cure this or that disease.

In closing this outline, allow me to say that should cholera visit us, some obligations are placed upon the medical profession, such as they have never had occasion to meet before. Since 1866, the last time any such widespread epidemic visited the Northern States, a great advance has been made in modes of investigation. Besides the kind of organization I have spoken of, there is need of a system of *collective* investigation, as applied to cholera, such as has not yet been definitely applied to any widespread epidemic.

No fear but that there will be enough post-mortems and enough biological and laboratory investigations. But what I desire to emphasize is the need of accurate investigation, by practitioners, of all the phenomena of cholera, and accurate record thereof at the time. For it is being pressed upon us that as to number of cases and as to virulence there are other determining factors than arrival, and also others than even locality. Temperature and dew-point, suddenness of changes and other climatological phenomena, need more close observation and record. Whether a diarrhœal tendency is widespread some days before an outbreak is another matter, as to which there are so many testimonies that we cannot afford to be without the most precise record of diarrhœal cases this summer; as to the day and hour of start, and the special or general symptoms.

Can it be true that diarrhœa in some of its forms is an attenuated virus of cholera? Read the section in the recent "Life and Labors of Pasteur" on "The Return to Virulence," and on the circumstances under which the attenuated germs which *constantly abound*, "weakened to such a degree as to have lost all virulence," are restored to a deadly virulence and again become capable of living and multiplying in the body (p. 246). Consider another fact stated by Pasteur (p. 226), "that the virulence may be entirely gone while yet the microbe lives," and then test by it some of those experiments in the Johns Hopkins laboratory, which would claim fully to decide the value of a disinfectant by its power to kill a microbe *in the laboratory*.

I believe this precisely recorded clinical observation must be pushed up closer alongside of these other observations which, with profound respect for laboratories, I must think are getting to be too much disjointed from those greater laboratories or experiment stations that are also in the hands of the experts in daily practice.

The British Medical Association and the International Medical Congress, at their last sessions, brought international collective investigation into prominence. But what we want just now is such a predetermined plan of recorded observations as shall give us the *minutiæ* antecedent to the dangerous stage of cholera, and all other details of a great many closely observed cases. Trusting, believing, as we all do, gentlemen, that our very precautions will be the best preventive of any epidemic if it does come, we thus seek to be ready to save all we can from attack or from fatal sickness, and, by a matured plan for observation and record of all cases, to add much to our information as to the prevention of this and other conveyable diseases.

THE URATES—THEIR EXCESS AND HOW TO REMOVE THEM.

BY T. C. SMITH, M. D.,
Of Aurora, Indiana.

One of the manifestations of imperfect assimilation on the one hand, or of excessive tissue-waste on the other, is often noted by what in former years was denominated the "lateritious deposit" in the urine. Such an imperfect assimilation is very often met with in the daily rounds of practice. It may be the result of too free an indulgence, habitual or incidental, at the table, especially in a highly nitrogenous course of diet, or by insufficient exercise after the free use of such diet, or by what is commonly spoken of as "catching cold."

It may, with much consistency, be claimed that our normal diet is of a mixed character. It is partly vegetable and partly animal, and as long as the balance between these two forms of diet is kept fairly adjusted, and the processes of constructive and destructive metamorphosis are kept about equal, there is little expectation of seeing any considerable deposit of the urates in the urine. The conditions are not favorable to cause their presence. But an excess of rich food, composed largely of the nitrogenous varieties, throws upon the liver an increased amount of labor in order to prepare such food for assimilation by the tissues of the body, and thus prepare it to favor the constructive metamorphosis. If the immoderate use of the nitrogenous variety of foods is carried beyond the capacity of the liver to carry out fully its part in the process of digestion, and the complete metabolism of the albuminoids, it then throws a part of its work on the kidneys, or rather it manifests the fact of the overburdened

condition of the digestive organs by an attempt to eliminate from the blood, through the kidneys, the partially-prepared nitrogenous elements that are floating in excess in the blood, floating there because the liver is unable to fully prepare them for assimilation and appropriation by the tissues of the system.

The remedy for such a condition is readily seen, viz., a less nitrogenous diet, or the complete exclusion for a time of all animal food.

A similar condition may be produced in any one who habitually takes a free amount of exercise, especially in the open air, but who, upon occasion, consumes his usual quantity of animal and other food, and then, instead of taking the usual amount of free exercise or labor, spends the hours after such hearty meals in sedentary quiet. The destructive metamorphosis is not as rapid as usual, the demand for constructive material is not as great as usual, and so an over-supply is left for the stomach and liver to dispose of. Not being able to maintain the balance between the two processes of supply and demand, it, in this case as in the other, throws the excess into the blood-current, to be eliminated by the renal emunctories, and thus free the system of material not needed in maintaining the normal standard of health, and which, by its decomposition, would cause disease. In this instance, we find the urine loaded with the urates, the same as in the first one named.

An exactly similar condition is produced by "catching cold." In this instance there may be no excess of food taken, but there is interference with the elimination of waste material by way of the skin, and the process of retrograde metamorphosis is for a time more or less retarded, according to the degree of interference the "cold" has produced. If such "cold" is contracted at a time when the blood and liver are already surcharged with an excess of the nitrogenous elements of food, or, if at the beginning, or in the early stage of such "cold," the subject takes an immoderate quantity of animal food, he will stand well in for an attack of so-called biliousness and some considerable pyrexia. I believe such surcharged conditions of blood may render the subject much more liable to an attack of pneumonitis or bronchitis, rheumatism, etc., than he would be if the reverse condition of the system was present. However, from this basis, any one can see the utter folly of the old advice which is still so often sounded in our ears, that we should "feed a cold." The very opposite of this course will always hold good in treatment. Especially will this prove beneficial when we withdraw all articles of nitrogenous food.

A similar condition of the urine may now and then be met with when the quantity of food taken is not immoderate or is even too small in quantity to maintain perfect health, and where at the same time the supply of drinking fluid is insufficient. In such instances the urates are in proportionate excess for want of enough fluid in the system to make the quantity of urine normal, and so dilute it to a normal standard.

It will be seen that the interference in the assimilative process occurs in the advanced stages of digestion. The stomach has done its duty, the process has continued in the small bowels, the bile and pancreatic juices have done their work, the absorbents have taken the food and carried it into the circulation. It reaches the liver ready to be further reduced and prepared for assimilation by the tissues of the body. As long as a healthy balance maintains, there is no excess thrown into the blood-current, and none thrown into it not fully prepared to go on up to the higher stages of constructive metamorphosis. But if too much work of this kind is cast upon the liver, the fact is at once made known by the appearance of the urates in excess in the urine. This is quickly discovered by the lateritious deposit, or better by the usual chemical tests now known to nearly every tyro.

We often meet with such a condition in old people who indulge freely in foods rich in quality, and who take but little exercise. We often meet with it in the subjects of sedentary employment and habits. These cases are brought to this state of system by a more or less complete failure of the metabolism of the albuminoids of the food eaten. The great hepatic organ has the lion's share of this part of digestion to perform. They may be and are thoroughly emulsified in the stomach, and their reduction is further advanced by the bile, and action of the pancreatic and intestinal fluids, so that they are adapted to the absorbent glands, made ready to be taken up by them. But digestion is not yet complete, or at least not complete enough to make the proteids completely ready for building up the tissues of the body. This is accomplished by that largest gland of the body, the liver. All the albuminoids have their final reduction completed there. If too much albumen is ingested, it soon appears in the urine in the form of the urates. If the amount of albumen taken is very immoderate in quantity, albumen, little if at all changed, appears in the urine, and is readily detected by the usual chemical tests.

The line of treatment in most of these cases must be governed by the conditions present and the causes underlying the same. An immoderate quantity of the urates floating in the blood is often attended with very serious and dangerous symptoms, and nearly always by considerable feeling of depression, general malaise, aching, soreness, headache, foul breath, large, flat, indented tongue, covered with a thick white fur or yellow coating. This condition long maintained leads to a gouty state of the system, and to more or less free lateritious deposit in the urine. Often, however, the urine seems clear and normal, but its specific gravity is found to be high. A few drops of nitric acid added to a small quantity of it, and then set it in a cool place, will soon develop the presence of a large amount of these salts. These placed under the microscope will place them just where they belong chemically. In hot weather it is needful to set the receiver on ice after the nitric acid is added in order to fully develop these salts, even if present in considerable quantity. The microscope will detect them very often when the urine seems to the eye to be clear of them.

To attend to the diet of the patient is one of the points in treatment that cannot consistently or safely be overlooked. To give the subject the proper remedies and still allow him to go on using freely of nitrogenous food is almost useless. Every article of this class should be cut off until there is no excess of the urates found in the urine.

To expedite the elimination of this effete material from the blood and general system rapidly and easily, I know of nothing superior to sulphate of soda—Glauber salts. They are very harsh to take unless properly prepared. Then they are as easy to swallow as are the Epsom salts, so much in common use. The following formula is a fairly good one to use:

℞. Sodæ sulphas, ℥j.
Acid sulph. arom., ♏xxx.
Sacchar. alb., ℥iij. M.

Sig.—Put this in a teacup, pour on boiling water until the cup is two-thirds or more full; stir until cool enough to drink, then swallow all at one dose. It should always be taken on an empty stomach.

This will be readily taken, operates quickly, easily, and gives large, free, watery discharges. It is sometimes needful to repeat the dose in two to three hours. This remedy, as stated by Fothergill, has a special action for and on the liver, and stimulates it to prompt action. Besides this, it seems to eliminate the urates freely from the blood, and to prepare the way for future treatment. It occasionally produces nausea or vomiting, but not often, if well prepared.

I have noted that many authorities recommend the free use of alkalies in this state of the system, and apparently for rational reasons. These alkaline salts do clear the urine of the lateritious deposit, and the patient improves; but if we have a case in which we cannot afford to greatly increase the destructive metamorphosis, we can hardly be willing to produce a further reduction of strength by their very free or continued use.

If the urine is excessively acid, the soda or potassa salts will be well enough to use for a while, but generally such urine will not be excessive in acidity, and will, I believe, be found to have become alkaline in quite a short time after it has been drawn off. Very frequently it is alkaline to a marked degree when first evacuated; and an alkali, under such circumstances, could only add to the trouble already present. This class of remedies, however, indirectly stimulates the digestive organs, and in addition to a withdrawal of all nitrogenous articles of diet, will thus accomplish the end in a few days in many cases, while in a few who are already greatly reduced in strength they have not acted happily for me. This is especially true in old subjects.

Very small and frequently-repeated doses of colchicum will act finely in those cases that have a very marked gouty tendency. Its administration should be accompanied with a very free administration of water.

Indeed, in many of these cases, the best possible remedy we can administer is water. We often find these cases—as we do many others—where the amount of fluid ingested is not sufficient to supply the demands of the tissues. The volume of the circulating medium is diminished because there is not a sufficient supply of fluid contributed to the system to meet the common demands. The patient is costive; urine high-colored, throws down a thick sediment; skin is dry and harsh; there is headache, languor, and mental hebetude. A dose of physic will make the case feel better for a brief time. But to such a patient—they are generally very small drinkers of water—give a little harmless remedy to be taken every hour or two in a glassful of good, pure, soft water, and he will soon feel quite a favorable change. The bowels will open, the urine become free and clear, the mind regains its elastic buoyancy, and the man that before was stupid and half-sick, now has all his machinery running as merrily as a marriage-bell.

The blood and lymphatic channels in such a system are much in the condition of some of the sewers of our large cities when they have not sufficient water flushings to keep them clean. They become foul, fetid, and pestilential. So the effete and decaying material that floats in the blood-channels of the animal economy causes all manner of ill symptoms, and often diseases of a low and disorganizing type.

In this free use of water lies much of the power of the mineral springs of the world. People go there in a state of ill health, many of them in conditions similar to that above described. They drink and drink and drink of the mineral waters until every artery, vein, and lymphatic channel is flushed with the excess of fluid. Water rushes out through the kidneys, out at every pore of the integument and every excretory gland. In this manner the whole system becomes thoroughly washed out, every particle of tissue has the effete, waste material all soaked out of it and flooded away. Of course the patient feels better, and is better. He therefore praises the virtues of the mineral spring as a boon to suffering humanity and a great blessing divinely given. It really and indeed is so to those who have not wisdom enough to use the pure water of their own cisterns or pure springs to the full free extent that common-sense internal cleanliness naturally demands. Some of the most noted mineral springs in the world—so-called—are almost absolutely free from any trace of any and every mineral substance. Yet these same springs have a world-wide reputation for the cure of some forms of diseases.

In the class of cases in hand, and where the urine is loaded with the urates in heavy excess, it will be well to open out the blocked-up sluiceways by the production of pretty free catharsis. The sulphate of magnesia is excellent for this purpose, but the sulphate of soda is preferable if properly administered. Any good cathartic will answer. A mercurial is not indicated unless there be a marked specific taint present.

After free evacuations have been procured, the use of hydrochloric or nitric acid will serve a most excellent purpose. The latter is preferable, but its action on the mucous lining of the alimentary tract is too sharp unless very thoroughly diluted. This is not so to the same degree with the hydrochloric acid. But either of these should be given with an abundance of water, and with as much sugar as the patient may desire. If the patient will not drink as much water as needed, he should have diluents given in large abundance, as these will serve a similar purpose. Acetic acid will often answer the same purpose in many cases.

Case I. A young married lady came to me some time ago complaining of great debility, constipation, dysmenorrhœa, dysuria, and of great scantiness of urine, very high-colored. The appetite was poor, headaches frequent and severe. The sediment in the urine was abundant and of a pinkish tint. It was also strongly alkaline. The tests showed a large amount of the triple phosphates present. She was put upon the use of hydrochloric acid in two-drop doses to be taken in a glassful of water every three or four hours and ordered to drink very freely of water. Was given a common bitter tonic, and all nitrogenous articles of diet were ordered to be stopped. Her recovery was prompt and readily accomplished. I should have stated that before coming to me she had passed several small calculi, perhaps of the phosphatic variety. I did not see them. She had been for some weeks on the alkaline treatment before this without receiving any benefit or relief from her symptoms.

Case II. Was called to see a gentleman some months ago, who at first, I thought, might be suffering from enlargement of the prostate gland. A closer inspection proved it to be one where the system was being poisoned by the retention within the system of the salts of the urine that ought to be excreted. The quantity of urine voided was quite deficient, quite red, very alkaline, very scalding, and had seemed to cause a very marked cystitis. He was feverish, greatly depressed, quite weak; breath had a readily noticeable urinous odor; skin dry and husky. A cathartic was administered; hydrochloric acid in large quantities of fluid was given; afterward acetic acid was substituted. Cinchonidia was used in tonic doses. All nitrogenous foods were cut off. In this case a good and prompt recovery was had, where death from uræmic poisoning was threatened, and little was to be hoped for in the way of complete restoration.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER, M. D.

Reported by W. H. Seelye, A. M., M. D.

Mitral Regurgitation.

Patient is 27 years of age, and a baker by occupation. Was admitted January 24. He gives no family history of any pulmonary difficulties, ex-

cept that his grandfather was subject to attacks of asthma. His parents were both healthy. He has never had any venereal disease, and only uses alcohol sparingly. He has always enjoyed good health until two years ago, when he suddenly became short of breath and had a dry cough, and complained of sharp lancinating pains in the chest. At this time he was confined to bed for two weeks. Since then he has kept at his work, but the shortness of breath and the cough have continued. He has never expectorated any blood. He also has been much troubled with headaches and with cardiac palpitations. His bowels and micturition are normal. During the present winter he has had attacks of rheumatism in the shoulder. Has not been troubled with nausea or vomiting. Two days ago he became so embarrassed for breath that he had to give up work, and then he applied for admission at the hospital in Chambers street, and he was sent from there to this hospital. On admission his pulse was 92, respiration 26, and temperature 99.6°.

Gentlemen, inspection shows you here a plainly visible cardiac pulsation, which is not confined to the præcordial space, but is diffused over the left chest as low down as the seventh intercostal space, and in the epigastrium even to the right of the median line, and the pulsation is rapid and wavy in character. Furthermore, there is considerable diaphragmatic movement in the respiration, and the breathing is largely abdominal. You see here some marks upon the anterior portion of the chest and belly, which were made by the doctor in his examination to indicate the position of the apex beat and the lower margin of the liver. The apex is three inches below and one inch to the left of the nipple, and the margin of the liver is considerably below the ordinary line of hepatic dullness. All these things you note by the inspection.

Upon palpation I find the expansive movement as well as the elevation movement of the chest very limited, and the respiratory movement is chiefly diaphragmatic. I can also perceive very distinctly the apex beat at the point marked in the sixth intercostal space, and at least one inch outside the nipple line. Still further, I feel that the sense of resistance in the abdominal region is especially marked in the right hypochondrium, and this indicates either an enlargement or a displacement downwards of the liver.

Upon percussion of the chest in front I get the upper margin of præcordial dullness at about the place where it is ordinarily found, at the fourth rib, and it extends down in a vertical line to the sixth interspace, and the outer margin is one inch outside of the nipple line. The area of præcordial dullness is therefore considerably enlarged, and he consequently has a very great hypertrophy of the heart. There is nothing very marked about the percussion over the lungs on either side, but there is a slight diminution of dullness upon the right side as compared with the left. The upper margin of hepatic dullness is at the upper border of the sixth rib, and it extends downwards in the abdomen to a line one inch below the umbilicus. We have here, therefore, a very considerable enlargement of the liver. I find also a very considerable increase in the area of splenic dullness.

Posteriorly, upon inspection while in the sitting posture, I find that with the aid of considerable voluntary effort he expands the chest very well. There is a very decided difference in the percussion note of the two sides. The left side is more resonant from the supra-spinous fossa down to the base of the lung. But there is not sufficient dullness upon the right side to indicate any extensive condensation of the lung, or the presence of any fluid. Upon auscultation I find the breathing good, and I get the respiratory murmur all over the chest posteriorly, but not quite so loud or free upon the right as upon the left side. This slight difference in the two sides may be due to the presence of old pleuritic adhesions on the right side, or to some persistent variation in the amount of blood circulating in the two lungs.

I also find upon auscultation a loud blowing murmur, which is most distinct over the apex, and it is carried to the mitral orifice, and even to the base, and in fact it is to be heard with some intensity all over the præcordial region. And I can also hear it towards the axilla, as is common with these mitral regurgitant or indirect murmurs. I can also hear it behind, though not very distinctly, at the junction of the seventh and eighth ribs with the spinal column, as is not infrequently the case. The late Dr. Cammon, and following him Dr. Clark also, believed that the transmission of a murmur to this location on the back was an indication of some organic defect of the valves, in contradistinction from simple blood murmurs. But then we are not dependent here upon this sign to determine the question of diagnosis, for the other evidences of an organic valvular disease are sufficiently clear without this.

Now, for a few words in reference to the history. This man is twenty-seven years of age, and gives no family history of importance. He is a baker by occupation. There is no history of any of those acute diseases which are apt to be complicated by cardiac disease; but he first had his attention called to his chest two years ago by reason of shortness of breath, and difficulty of breathing on exertion; and at the same time he had some cough. But the palpitation and the dyspnœa were the symptoms that especially attracted his attention, and they have existed ever since. Now, this is not the history of the great majority of these cases, for you are able, ordinarily, to find a history of an acute cardiac affection, originating it may be from some infectious fever, or in the course of an attack of Bright's disease, endocarditis, or pericarditis. Or what is even more common, is a history of a former rheumatic fever complicated with an endocarditis. But here there is nothing to fix the date of the beginning of this trouble. Now, it is entirely possible for this disease to have developed itself gradually. The insufficiency of the valvular orifice may have been going on, increasing slowly, without attracting the attention of the patient or stopping him from pursuing his daily occupation. There are many cases of cardiac disease of this description, and this is especially true of adults and of persons well on in life. In many cases in adults there are slow changes going on in the cardiac valves, as the result of senile degeneration. But it is just possible that in early life this man may have had an acute illness, in the course of which there

occurred an acute endocarditis. And the fact that he does not give any such history is owing to the imperfections of the memory, or "to the anamnesis of the disease," as the Germans would say. It is, therefore, possible that he may have had in early childhood a disease of which this is the consequence; and two years ago was that time which finally comes in the history of all cases of heart disease, when the compensation is not equal to the demands of the circulation. Often the patient's attention is not drawn to the heart until the heart muscle can no longer overcome the obstruction of the circulation in the lungs. But whether the true history in this case is one of senile change, or of an early disease, is not, perhaps, a question of very great importance. What we have to deal with here is evidently an extreme hypertrophy of the heart with mitral insufficiency, and a condition where compensation is no longer taking place. The effect of this loss of compensation here has been to produce some difficulty in breathing, and an enlargement of the liver and spleen. There is no systemic dropsy, but simply a congestion of the lungs and abdominal viscera.

The clinical management of cases of this sort involves the consideration of two separate conditions. First, the condition in which you find this man, for the relief of which very active measures are required; and second, a less severe condition, such as exists after all the urgent symptoms have subsided. Both these conditions require the special attention of the doctor. I hove spoken to you many times about the clinical management of patients with great dyspnœa and congestion of the lungs and liver, and with systemic, ascitic, and pleuritic dropsy, and you know very well already the course of treatment in such cases. So I will rather speak now of the management of those cases in which everything is in the best possible condition already. I maintain these people are entitled to the most explicit directions and the most thoughtful consideration of the doctor. In the first place you should lay before the patient the necessity of having an occupation which will make no great strain upon the circulation. And this involves also the avoidance of all undue emotional excitement, and of everything which is disturbing to the equilibrium of the circulation. Then again you will find that it is of extreme importance that you should give the most strict injunctions about the food. This is often a thing of so much inattention and carelessness that I insist upon it as a matter of primary importance. A great deal of the distress in heart disease is the result of irregularities of diet. If these patients are allowed to become dyspeptic they will surely have to suffer for it. The general management of the diet therefore should be such as shall secure the patient against dyspeptic troubles, and especially against that variety known as acid dyspepsia. And you should select such food as will avoid this trouble. They should not take any considerable quantity of carbonaceous foods, or any food that they know does not ordinarily agree with them. Thus sweet and farinaceous foods, and all fatty foods, are often found to disagree. And there is still another reason why you should not give them, and that is because this class of food is calculated for the diet of those persons who have to exert a great deal of muscular energy in their business. But here you want to diminish the muscular energy, and to keep them from physical exertion. But they may engage in intellectual occupations, or do the lightest kind of work. The animal foods, with fruits and green vegetables and well-cooked bread as the only starchy elements of the food, make up the diet best fitted for them. Again, they are almost always made worse by alcoholic stimulants, and so they should not be allowed to take wine or beer, or any other fermented liquors. These are details of vastly greater importance than the administration of drugs.

The drugging of these patients is always to be rational, and for a special purpose. Here the lungs, and liver, and the chylopoietic viscera are much congested, and you can do something to relieve this by purgation, and occasional diuresis. It is often necessary to relieve general congestion as well as localized stasis; and this may be accomplished by allowing them to drink freely of fluids which shall encourage diuresis. Again, it is often necessary in these cases to stimulate the heart's action, and you can do this with heart tonics. And the one of greatest value in this form of disease is digitalis. But there are others which act in very much the same way as digitalis, and still others which act in a different way. I will not say any more about drugs, however, for I only want to impress upon you to-day what I said in regard to the hygienic management of cardiac disease.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, June 4, 1885, the president, B. F. Baer, M. D., in the chair.

Biniodide of Mercury as a Disinfectant in Obstetrics,

by Dr. E. R. Bernardy.

My attention was first attracted to the use of the biniodide of mercury as a germicide by Dr. Miguel, who published in *L'Annuaire Meteorologique de Mentsonn's* the results of some experiments made to determine the minimum amount of a disinfectant necessary to prevent fermentation in a litre of sterilized beef-broth. His experiments show that the mercurials are the best antiseptics, the biniodide being nearly three times as strong as the bichloride. In his table of disinfectants he places the bichloride the fourth on the list. To a litre of sterilized beef-broth, he found it required 0.025 grammes of biniodide of mercury to keep the broth pure; while 0.070 grammes of the bichloride of mercury was necessary to produce like effects. This shows that bacterial life is impossible in a solution of one forty-thousandth part of the biniodide, while of the bichloride it requires the $\frac{1}{14000}$ part. I was so fimly impressed with his experiments that I determined to give the biniodide of mercury a trial in obstetric cases where it would be necessary to use an antiseptic. The following are the cases in which it was used.

Case 1. On February 7, 1885, I was requested

to take charge of Mrs. D., who had been confined about six weeks previously. It had been her second confinement, the duration of labor had been short, and delivery natural, but an extensive laceration of the perineum had occurred. No attempt had been made to bring the parts together by suture. On the third evening she had been attacked with severe frontal headache and chills, followed by fever with great tenderness over the region of the uterus. There being no improvement in her condition, her medical attendant was discharged, another called in who gave such an unfavorable prognosis that he, also, was requested to cease his attendance. I was finally called in on the above date. The patient had well-marked symptoms of septic poisoning; pulse 130 to 140, small and thready, and disappearing under pressure of the finger; temperature 104° to 105°; slightly delirious; constant vomiting; abdomen swollen and excessively tender; uterus enlarged, extending fully three inches above the pubis. In the right side there seemed to be a growth extending up into the abdomen, tender on pressure. On making a vaginal examination, I found the os dilated so that my index finger could readily enter the uterus. Its withdrawal was followed by a gush of highly-offensive matter. The uterus was surrounded by organized lymph, and was immovable. The mass on the right side was easily detected, and was continuous with the lymph surrounding the uterus. The vagina was hot. The perineum was torn to the anus; the surface raw and secreting an acrid matter which scalded the surrounding parts. The urine was dark; on standing, a reddish material settled to the bottom; it looked like blood corpuscles. Dr. A. E. Roussel examined the specimen, and reported it to be slightly acid, no albumen nor sugar; under the microscope, occasional pus corpuscles, and swarming with bacteria. In conjunction with internal treatment, intra-uterine injections were made three to four times a day. I first used a solution of bichloride of mercury, 1 to 2000. This was continued for three days without any marked results. The discharge continued as offensive. On the fourth day the bichloride was substituted by a 1 to 4000 solution of biniodide of mercury. Within twenty-four hours an amelioration of all symptoms took place, the pulse fell to 100, temperature, 101°; urine became clear, and the discharge odorless. The injections were continued for ten days, their frequency being gradually reduced. The uterus returned to almost its normal size, and the lymph was gradually absorbed. The patient recovered.

Case 2. March 19, 1885, I was called to attend Mrs. W. in her first confinement. On my arrival, found she had been in labor several hours. Examination showed the os perfectly dilated; bag of waters protruding; vertex presentation, first position, ruptured the amnion. The vagina, near its outlet, was roughened with venereal warts; these spread, also, over the vulva. Labor progressed rapidly, and the second stage was happily ended. After wasting nearly an hour making compression on the uterus, I made slight traction on the cord, and while doing so, felt, with my hand upon the uterus, a cup-like depression of the fundus take place. This convinced me that I had an adherent placenta to deal with, and it would be folly to wait any longer. On introduction of the hand I found the placenta completely adherent; one could hardly say which was uterus, which placenta. After considerable trouble, I at last succeeded in detaching the placenta; it took fully three-quarters of an hour. On making a second examination to ascertain if all had been removed, my hand came in contact with long shreds hanging from all sides of the uterus; the more I scraped, the more there seemed to be. I gave the patient f. ʒij. of the extract of ergot. The patient did well for two days, when toward evening, she complained of a chill and severe frontal headache. I gave her quinia sulph., gr. x., with morph. sulph., gr. ¼, at one dose; washed out the uterus with 1 to 4000 solution of biniodide of mercury. The pulse was 115 and temperature 102°. The discharge was highly offensive. The injections were repeated every four hours. On the evening of the next day the pulse was 98, temperature 100°, discharge odorless, and the patient was perfectly well in ten days more.

Case 3. April 23, 1885, I was requested to call at once to see Mrs. K. who was reported in imminent danger of death. This was her ninth confinement. The history of the previous ones, with one exception, was not good. Her labors were natural, but were followed by terrible flooding and protracted convalescence. I found the patient in an attack of puerperal convulsions. I gave at once grs. xxx. of potass. bromide, and grs. xx. of chloral hydrate; this dose was repeated in half an hour; ten minutes later another convulsion occurred. I then bled the patient freely. The os uteri was somewhat enlarged, the cervix soft and dilatable; vertex presentation. Dr. Curtin, whom I had sent for, having confirmed my opinion, and considering that the patient's time was quite up, we decided to etherize, dilate the cervix, and deliver. The forceps were applied, and traction made at intervals. A living child was safely delivered. Continuous pressure was maintained over the uterus, but after the expulsion of the placenta the uterus did not contract until it had been washed out with hot water. The bromide and chloral was continued every two hours, and no more convulsions occurred. The patient did well up to the fourth day, when the discharges became very offensive, the pulse accelerated, and slight tenderness existed over the uterus; no chill or fever. The uterus was thoroughly washed out with a solution of one to four thousand biniodide of mercury. Within twenty-four hours the discharge became odorless, and the tenderness over the uterus had disappeared. The patient recovered after a tedious convalescence.

In these cases it will be seen that the biniodide was prompt in its action, markedly so in Case 1, where the bichloride and the biniodide were both employed, the result being decidedly in favor of the biniodide. Naturally it will be said, here are only three cases from which deductions are to be drawn, and it is only after it has been carefully used in a large number of cases that its efficacy can be proven. It is for this reason that I call the attention of the members of this society who are in a position to give it a fair and impartial trial, and at some future time give the results of their investigations. I have found the 1 to 4000 solu-

tion of the biniodide non-irritating. I have used it extensively in my gynecological practice, and in washing out pus cavities, with good results. In it we have a preparation where the smallest amount of drug is used, with results far exceeding those of any other antiseptic. On account of the small quantity of mercury there will be less chance of salivation.

The method I have pursued in making the solution is: Take three and a half grains of the salt well triturated in a mortar and rubbed, with one quart of boiling water slowly added, giving a solution of 1 to 4390.

Since writing the above, I have seen in the *Philadelphia Medical Times*, May 16, 1885, that Dr. Panas, Eye Surgeon of the Hotel Dieu, used the 1 to 25,000 solution of biniodide of mercury in eye cases. He makes the following statements: "After a number of experiments, I have convinced myself that a solution in water 1 to 10,000 of the bichloride, or a similar solution 1 to 25,000 of the biniodide of mercury is much superior to any other antiseptic solution employed in eye surgery." Here again we have a statement that the biniodide in a smaller quantity is as good an antiseptic as the bichloride.

Dr. Montgomery's experience has led him to the conclusion that the bichloride of mercury is far more effective as a disinfectant than carbolic acid. Its introduction into the Philadelphia Hospital was due to Dr. Parvin, who found it very satisfactory. In eighteen cases of puerperal fever that were treated with bichloride injections, only three deaths occurred. This success was attributed by the hospital staff to the use of the bichloride. Dr. Montgomery in private practice follows the plan of Dr. Garrigues, of New York, and avoiding intra-uterine injections after labor, but applies pledgets wet with a bichloride solution over the vulva, after carefully cleansing away clots and washing the external parts with a similar solution. This sponging is repeated twice every day. In his last term at the Philadelphia Hospital he had only two cases of puerperal fever, one of which commenced twelve days after delivery. The history of Dr. Bernardy's cures shows an equal if not better antiseptic in the biniodide of mercury.

Dr. J. V. Kelly some years ago had several fatal cases of puerperal fever, and almost twenty-five cases that got well. The trouble commenced in a case of abortion, in which he did not succeed in removing all of the placenta. He was at the same time attending a bad case of erysipelas; and at that time the relationship of puerperal fever and erysipelas was not known to him. He was on the point of giving up his practice and leaving the town, and consulted Dr. Goodell on that subject. Dr. Goodell discountenanced such action, but advised him when attending an obstetric case, to remove his coat and roll up his sleeves, and wash his hands and arms well with turpentine, using the nail-brush thoroughly. Since that time he washes his hands in turpentine every day and again before every case of labor. He also uses a wash of vinegar or carbolic solution before touching a puerperal patient. He has had no puerperal fever or other septicæmic symptoms since that time.

Dr. Parvin said as a reference has been made by Dr. Montgomery to my having used corrosive sublimate vaginal injections in the cases of puerperal septicæmia under my care in the Philadelphia Hospital in my term of service last year, I will refer to the antiseptic treatment in the cases occurring the present year. When I took charge of the obstetric ward on the first of January, I found five recent cases of septicæmia; two of these patients died; one of the two had apparently recovered, and then was attacked by pneumonia; quite possibly this pneumonia had a septic origin. Then there was at least seven other cases, but all these, as well as three of the original five, recovered. Injections of a solution of corrosive sublimate, 1 to 5000, were used in all cases immediately after labor; the external parts were washed, too, with a similar solution. This injection was repeated twice a day in all cases for the first week after labor, while it was used oftener in those having septicæmia; intra-uterine injections were used only when vaginal injections failed to correct the offensiveness of the discharge, but as is well known, there may be serious, even fatal, cases of septic disease, though the lochial flow is not at all offensive.

In private practice, after once washing out the vagina thoroughly with the antiseptic solution immediately after labor, this need not be repeated unless symptoms demand it, but the bathing of the vulva twice a day with the solution ought not to be omitted. Add, if you please, to this treatment, the use of antiseptic napkins, a practice pursued by Dr. Montgomery at the Philadelphia Hospital so successfully, and I think we have taken the most important means to guard against the entrance of septic germs after labor.

He has had no experience with the biniodide of mercury, and does not know that it will supersede the bichloride. The argument in its favor is as strong as three successful cases can make it; but these are entirely too few, as Dr. Bernardy justly says, to prove its value and its superiority. In one of the doctor's cases labor was induced, apparently, on account of eclampsia. Now, is this the best treatment? Obstetricians are by no means agreed, some of the best condemning such treatment. But the subject is not properly before us now, and therefore no further remarks will be made upon it.

Dr. Montgomery uses the bichloride solution as an external wash only, not as an injection. He thinks that the records of the hospitals in which injections are used will not show as good results as those in which they are omitted, if septicæmia be not present.

Dr. Willard had a warning to sound with regard to the use of bichloride solutions of stronger grades. He had been using washes and antiseptic dressings made with a 1 to 1000 solution of bichloride, but in consequence of what was written about the advantages of stronger solutions, he increased the strength of his dressings to 1 to 500, and within twenty-four hours the stools contained bloody mucous, and were small and griping; there was vesication about the wound and around the limb under the dressings. Entirely dry dressings had been used, but they had been moistened by pus and serum from the wound. He does not see the advantage of strong solutions in serum as 1 to 100 or 75. The serum is a decomposable sub-

stance, and an uncertain portion of the antiseptic agent is destroyed by it; weak solutions in boiled water seem more reasonable, and answer every purpose.

Dr. Longaker has been much interested in the third stage of labor, and would like to hear how Dr. Bernardy removed the placenta in the adherent case narrated by him. He has been using Crede's method with great satisfaction. He thinks the hand should be kept out of the parturient canal as much as possible. He does not need vaginal injections after labor, but depends upon outside washes. He finds that the temperature rarely rises during the puerperal period, even after instrumental delivery. He thinks care during the third stage will avoid the necessity for antiseptics.

Dr. Parish agrees with Dr. Parvin's views. He has found a solution of 1 to 1000 of bichloride irritating, and he now uses 1 to 2000 or 5000. Strong solutions cause an appearance resembling erysipelas or inflammation of the derm. Injections are not necessary in every case where the surroundings are cleanly, and the patient a multipara, he does not use them; but in primipara, with contusions or lacerations, and when version or instruments have been employed, he is in the habit of injecting a weak solution of bichloride immediately after delivery, but he does not repeat it, but simply washes out the vagina. Cleanliness of hands, instruments, and nurse is the most important point. He has never had any trouble in private practice.

Dr. Bernardy, in closing the discussion, remarked that he thought he had a far better antiseptic in biniodide than the bichloride. He had used the former in surgical cases also, washing out pus cavities, and always with good results. He does not use intra-uterine washes in every case of labor. He has attended since the first of the year about seventy cases of labor, and he has employed the intra-uterine injections in only the three cases detailed. In every case of labor he uses carbolic acid soap to cleanse his hands and arms, and the external genitalia of the patient. The eclamptic patient had reached or passed her full term, and there was no reason why the child should not be removed. In the case of adherent placenta, it was pulled off forcibly, and a shreddy lining was left in the uterus, as no line of separation had formed. He believed the dangers consequent on passing the hand and arm into the uterus and vagina are much exaggerated, and he does not hesitate to do so when the exigencies of the case demand it.

(*To be continued.*)

—Dr. Fleischl, of Vienna, declares that morphinism, alcoholism, and similar habits, can now be cured rapidly and painlessly by means of cocaine chloride. The method is very simple—a withdrawal, either gradual or abrupt and complete, of the habitual intoxicant, and treatment of the nervous and other symptoms which arise therefrom by means of hypodermic injections of the cocaine. He claims that in ten days a cure may be effected in any case. The dose of cocaine chloride hypodermically is from $\frac{1}{12}$ to $\frac{1}{4}$ grain, dissolved in water, repeated as necessary.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, February 27, 1885. The president, Edward E. Montgomery, M. D., in the chair. Dr. Montgomery reported several cases of

Abdominal Surgery.

No. of Patient.	Age, Years.	Disease.	Operation.	Hospital or Private Practice.	Date.	Result.	Remarks.
1.	28	Ovarian tumor. Left ovary.	Ovariotomy.	Hospital.	May 17, 1879.	Recovery.	Right ovary contained *two* small cysts. Since been pregnant.
2.	35	Cancer of uterus and rectum.	Colotomy.	Hospital.	April 28, 1880.	Recovery.	Survived one year. Was able to attend to herself, and had no discomfort.
3. Col'd.	53	Multiple fibroid.	Hysterectomy.	Hospital.	May 5, 1880.	Death.	Fifty-three hours. Peritonitis and exhaustion. Tumor weighed 12 pounds, partly calcified. Aorta atheromatous.
4. Col'd.	46	Fibroid.	Hysterectomy.	Hospital.	March 17, 1882.	Death.	Shock 27½ hours. Ureters dilated. Kidneys sacculated. Tumor weighed 16 pounds.
5.	46	Epithelioma of larynx and œsophagus.	Gastrostomy.	Private practice.	December 17, 1882.	Death.	On fourth day beginning peritonitis. Had been supported three weeks on injections.
6.	17	Menstrual epilepsy.	Oöphorectomy.	Hospital.	September 13, 1881.	Recovery.	Convulsions less severe. An interval of three months between epileptic attacks.
7.	30	Cyst of broad ligament.	Laparotomy.	Private practice.	October 9, 1884.	Recovery.	Cyst was enucleated and the right ovary removed.

Cases 1, 3, and 4 were done under antiseptic precautions; 6 and 7 without. He objected to the spray, saying it increases the peril of the patient, by the prolonged chilling of the peritoneum, by absorption of a deleterious agent, and by the increased organic matter washed into the wound from the impure air of the room.

Dr. L. Brewer Hall presented the following case: "Mrs. S. applied to the Philadelphia Dispensary February 17, 1885, seeking relief for a rapidly-increasing loss of vision. She has always had excellent health, has given birth to five children, and is now pregnant for the sixth time, and thinks she is now in the eighth month. At present she feels perfectly well, except her eyesight, which has failed rapidly during the past few weeks; has no aches nor pains anywhere, and has a good appetite.

"Her vision upon entering the Dispensary was R. $\frac{1}{60}$, L. $\frac{2}{60}$; read Jæger with difficulty. The exterior of the eye appeared perfectly healthy. The ophthalmoscope, however, revealed the existence of *retinitis*, and that peculiar form characteristic of kidney disease, *retinitis albuminurica*. The urine, upon examination, on the 18th inst., showed a moderate amount of albumen ($\frac{1}{5}$ to $\frac{1}{3}$ bulk), with a few large granular tube-casts, mingled with much squamous epithelium, confirming the diagnosis made upon the appearances in the eye."

Dr. Montgomery questioned the importance of the induction of premature labor.

Dr. Hall, in reply, said: "That would depend on the amount of inflammation and the stage of pregnancy. This deposit of fat in the retina is generally absorbed rapidly. *Exudation* of lymph into the retina near the disc, is not so rapidly taken up. If the disc is being choked rapidly, the induction of premature labor should be considered. In this case the patches are diminishing, the inflammation seems to be subsiding, so there is no indicatfon to induce premature labor."

(March 1, the patient was delivered of a still-born fœtus, and there was a marked improvement in her eyesight immediately.

Periscope.

Manganese as an Emmenagogue.

Dr. Frank H. Martin thus writes in the *Chicago Med. Jour. and Examiner*, February, 1885:

"From my observation I have been led to consider manganese in any form a direct stimulant to the uterus and its appendages. It may exert this influence by acting as a direct vaso-motor nerve stimulant to the vascular system of the parts, and in consequence of the improved circulation directly increase the tone and nutrition of the organ, as it may exert its whole force through stimulation of the sexual nerve ganglia, or even possibly the sexual nerve-centres, thereby bringing the organs to their normal state of action." At any rate its action is prompt, and direct in bringing the uterus and appendages to a normal state of menstrual tonicity, when the lack of tone is dependent upon some previous depression of innervation.

It will be seen by the following typical cases, that even when the cause of the depressed innervation is still acting, this remedy will exert its stimulating power over the menstrual mechanism. A young woman, eighteen years of age, in consequence of phthisis, had not menstruated in four months. Experimentally I gave her manganese. Menstruation occurred within a week. "Another young woman, twenty-four years of age, with an aggravating digestive trouble of some years' standing, had become very irregular, flowing profusely for a week or two, then scantily for an equally irregular time, again followed, perhaps without warning, by a profuse flow, or as likely complete cessation. This state of affairs had been going on for more than a year. There was no dysmenorrhœa. She was very weak and anæmic from the effects of indigestion and loss of blood. This patient was given two grains of the permanganate or potash dissolved in one-half glass of hot water every night on retiring. It was kindly received in this way by the irritable digestive organs. In a very short time there was a decided improvement in the menstrual trouble, and the patient has since menstruated three times normally."

"In young girls who are irregular in the early months of menstrual life, where it is simply caused by the natural weakness of the partially-developed organs of generation, or where, from an overworked nervous system, the organs are robbed of their natural nerve force, this remedy seems to possess the stimulating properties requisite to bring them into healthy action. A remarkable case of this kind was that of a young girl who had menstruated once. Eight months had passed and the menstrual flow had failed to appear again. The mother of the girl being alarmed sought advice. The permanganate was given in two grain doses twice a day. Within a week the girl menstruated the second time in her life. In two other cases of 'missing' in young girls, without any apparent cause or any other symptoms, the remedy given in the same doses a few days before the next regular period was expected, stimulated the organs to a normal flow. The action of the manganese was so prompt in these cases that I am convinced it was no coincidence." Since the above report was made I have been able to add many similar cases to my list, and the results have been invariably as gratifying.

"It is well known that from exposure to cold the weakest organs of the body are the ones most liable to suffer. A woman who, when exposed to cold, immediately suffers suppression, cessation, or excess of the menstrual flow, will invariably

be found to possess susceptible and weak menstrual organs. In cases of this kind, viz.: suppression, cessation, or excess of menstrual flow, caused by catching cold, with no other apparent cause, the most gratifying and prompt results are obtained from manganese. The above variety of cases are of so frequent occurrence that in them I have had numerous opportunities to test the new remedy, and I have yet to see it fail in either amenorrhœa or menorrhagia, when due to irritation of cold alone. In several cases where the flow was a week or ten days overdue from catching cold, the permanganate was given in large doses, and its almost magical effect demonstrated by the flow appearing within twelve hours."

My principal object in making *this report* is to emphasize the fact that manganese is a general stimulant of the menstrual organ, and in consequence of its stimulating power is an efficient remedy in certain forms of *menorrhagia* and *metrorrhagia*. In my report one year ago, I mentioned this point, but at that time my opportunities for testing the drug in that direction had been somewhat limited. I said at that time:

"Although I have had greater opportunities for testing the value of manganese in *amenorrhœa* than in *menorrhagia* or *metrorrhagia*, I have received unmistakable evidence of its power in the latter forms of menstrual trouble."

"Menorrhagia and amenorrhœa in their outer manifestations are exactly opposite in nature, but they are very often dependent upon the same causes. When the cause is anæmia, or any depressing constitutional disease, producing a perversion of the functional activity of the menstrual organs, and their *perverted* action consists of an *irregular* or *excessive* flow, this condition will as readily succumb to the stimulating effects of manganese as when the opposite condition exists. The following cases are of interest: A woman, aged twenty-six, sought advice for excessive and irregular flowing. She had been married two years, and had one child, twelve months old. The child was large and strong, the mother physically slight. The mother nursed the child, and for ten months stood the strain very well, when she commenced to fail, suddenly grew weak and anæmic, and began to flow excessively. This continued with but a few short irregular remissions, until I saw her at the dispensary. She was given two-grain doses of the permanganate of potash four times a day. At the same time all other treatment was withheld. In three days the patient returned, saying that the flow had stopped the next day after receiving her medicine. I then discontinued the manganese, prescribed iron and nourishing food, and she continued to improve. By digital examination nothing abnormal was revealed in the above case. Another case was that of a large, stout woman, thirty-five years of age, who came to the dispensary suffering from menorrhagia. Her menstrual periods were regular as to *time*, but the quantity of blood was alarmingly excessive, and would last for two weeks. She was married, had three children, the youngest three years of age. This abnormal condition of menstruation had been coming on by degrees for a year. The uterus was a little enlarged, and soft to the touch; otherwise, by physical examination, nothing abnormal. Four days before the expected flow, she commenced taking the permanganate in two-grain doses, three times a day. Menstruation came on at the expected time, and after a normally free flow for four days, passed off naturally. Before the next period the same treatment was repeated, with the same marvellous result." The above histories were written a year ago. Since then I have seen a great many cases of menorrhagia and metrorrhagia succumb to the effects of manganese. I have complete histories of a number of these cases which might be of interest, but will be content to mention a few typical cases taken from the case-book of Dr. S. F. Bradley, of this city, a gentleman who has taken considerable pains to test the value of manganese in menstrual troubles.

1. "Mrs. D——, aged thirty-three. Treated during winter and spring of 1883 for chronic endocervicitis and endo-metritis; and enjoyed good health until August 10, when she was taken with menorrhagia, which lasted six days before medical advice was sought. Gave in succession ergot, gallic acid, hot injections, injected tincture of iodine into uterine cavity, and finally plugged cervical canal with sponge tent which remained twenty hours. Hemorrhage still continued. Then ordered capsules, each containing two and one-half grains of permanganate of potash, one to be taken every three hours. Flow ceased shortly after taking the second capsule.

2. "Mrs. F——, aged thirty. Made first visit January 19, 1884. Three weeks before had a miscarriage at three months, and was attended by a midwife. January 19, began flowing excessively, and suffered much pain in uterine region. Detected by digital examination a piece of placental tissue about size of hen's egg in uterine cavity. Removed with fingers, and flow ceased. From this time until February 24, she improved rapidly from her anæmic condition, but at the above date menorrhagia began and was excessive. Ergot (℥ j. fl. extract every two hours) was given during the night with no cessation of flow. The following day ordered two-grain capsules of permanganate of potash. Hemorrhage ceased in two hours after taking first capsule.

Case 3. "Mrs. McF——, age thirty. Two children, youngest one and a half year old. Began flowing in the middle of September, 1883. She sought no medical advice until October 15. The hemorrhage had rendered her exceedingly weak and anæmic. Gave ergot and elixir ferri quin. et strych. She continued this prescription for ten days with no benefit. Ergot and gallic acid were then used with no amelioration. Careful examination revealed no enlargement of uterus—no tenderness—very slight laceration of cervix. On the 28th of October ordered two-grain capsules of permanganate of potash, one every four hours. One hour after first capsule had been taken the flow ceased suddenly. The capsules were continued until three or four had been taken. Saw her a few weeks ago, and her health had been excellent.

Case 4. "Mrs. B——, age thirty-five. Five children, youngest two years. Laceration of cervix (bilateral). Uterus four inches in depth. Chronic endo cervicitis and endometritis—slight prolapsus. Treated her for uterine trouble a couple of months previously, and had advised operation.

During the middle of October was taken unwell; flow never so profuse; had continued several days before seeking medical advice. Ergot, mineral and vegetable astringents had no effect. Gave the permanganate in two-grain doses. Shortly after first capsule was administered the flow began to diminish, and ceased entirely after the third had been given."

As has been demonstrated in the foregoing cases, the action of the drug is very prompt where indicated, and if discriminately given I am sure similar gratifying results will be obtained by others.

A Short Note on Two Cases of Stricture of the Rectum.

Dr. Oscar J. Coskery thus writes in the *Maryland Med. Jour.*:

In August, 1884, I was requested to see Mr. J. B., aged 43. The history of his case was, that during the last war in this country, while serving in the army, he became afflicted with hemorrhoids. Later, in 1877, an abscess made its appearance in the buttock, which, bursting at different points, left several sinuses; as these closed, it seems, with very little treatment, symptoms of difficulty in defecation came on, together with occasional discharges of blood *per anum*. These symptoms steadily increased until, when I first saw him, his condition was as follows: A tall, spare, dark-complexioned man, with dark hair and eyes, and an expression of countenance suggestive of habitual suffering. He had been complaining for a few days of what he called diarrhœa, but what, upon investigation, proved an almost incessant call to stool, though very little passed at each time, with great pain and some blood. By digital examination several distinct nodules were discovered, partially occluding the lower part of the rectum, and, at about two inches above the anus, a hard ring, which prevented the finger from penetrating further, even although considerable force was used. On this account, the extent of the constricting band could not be made out. Great pain was elicited by the examination, but very little bleeding followed. From the smooth feel of the stricturing band, though the patient was above suspicion, it was decided to put him upon specific treatment. This was faithfully carried out, but, in despite of occasional remissions, the patient steadily emaciated, the rectal symptoms increased, and upon making a second digital examination the obstruction was found to be greater. Believing that I had a case of malignant disease of the bowel to deal with, I advised colotomy. The patient only consented when his trouble had so increased as to make life unbearable. On November 7, 1884, I operated. The operation was exceedingly long and tedious, occupying fully an hour, because of the descending colon being, as I had not found it in former colotomies, contracted to the size of the little finger. It was not until, when from its anatomical position and relation to the kidney, I felt it could be no other portion of the intestinal canal, that I brought it out and stitched it to the skin. When the gut was opened, no fæcal matter escaped. The wound was dressed in the usual way, and next morning a small quantity of fully-formed fæces was found to have escaped. During the night of the second day a very large quantity came away. The wound at first did well; the patient, however, never did; a low form of peritonitis made its appearance, and on November 14, exactly one week from the date of operation, the patient died.

On January 22, 1885, I was called to see Nellie B., aged 14, the youngest of three children of the above. The history of the case was as follows: Ever since she could remember she had had pain and difficulty in defecation; that about four years ago the nurse had first noticed a decrease in the size of the stool. These symptoms had lately become much worse, and now she spends an hour and upwards in the closet before she can feel that she has relieved herself. She, also, now suffers from occasional attacks of "cramps," irrespective of the efforts at stool. Her stools consist of bands of solid matter, generally with a small quantity of blood, sometimes only streaked, at other times there passed as much as a tablespoonful of free blood. The quantity varies with the difficulty in defecation, and is referred, by her, to the straining. The ribbons of fæcal matter are about one-quarter of an inch broad by one-eighth thick. The child was sallow, undersized for her age, had never menstruated, and was thin. Her general condition was what might be considered moderately good, but she was old-fashioned and "Paul Dombeyish" in her ways. Upon attempting a digital examination, great pain was elicited, with spasm of the sphincters, and about one inch and a half above the anus a strong circular band was found, which would not admit my finger, perfectly smooth to the touch, and pressure upon which with the tip of the finger caused the child to scream (I should mention that she was very hysterical and very nervous under the examination). No blood or fæcal matter was found upon the finger when withdrawn, but a small quantity of blood was passed by the patient very soon after. To allay the great irritability, a very small suppository of opium and belladonna was ordered. After continuing this alone for some weeks, with no improvement, the child was put upon cod-liver oil. On March the 5th I found her wonderfully improved in general appearance. She is much stouter, has a good color, the rectal trouble has improved. Both she and her nurse state that the size of the *ribbon* has increased, and that she has passed no blood since taking the oil.

—At a meeting of the St. Louis Medical Society (*Weekly Medical Review*), Dr. Williams presented the history of the following interesting case: A young man in Carondelet had been deaf for several years, and during all this time he had dizziness to such a degree that sometimes he would fall. Besides this he had convulsions which were regarded as epileptic. On examination of his ears, they were both found to be plugged up with wax; and when this was removed, not only did the deafness disappear, but the dizziness and epileptic symptoms also went away. It is well known that affections of the drum may be the cause of the decided dizziness.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

DON'T SEND ME TO THE HOSPITAL!

Every one who comes in contact with the sick poor must be struck with their reluctance to enter a hospital. No matter how miserable the room, how bad the nursing, how indifferent the medical attendance, they decline, or, at all events, accept with great reluctance, the best skill and care the profession can provide, aided by abundant means, in hospital wards.

This behavior we often hear ascribed to ingratitude, to prejudice, to stupidity, or to pride. There is another consideration, however, which in recent years exerts still greater influence upon the poor patients with whom we have come in contact ourselves, and that is, a dread of becoming subjects for experimentation rather than patients for cure. They very naturally are not eager to enter an institution that is chiefly used, as they suppose, as a school for training students and demonstrating operations. The men of science in these institutions are, moreover, believed by them to make but little distinction between a helpless pauper and an animal for vivisection. They think, in their ignorance, that those who are in the daily habit of performing agonizing experiments upon living creatures, deliberately intended not to heal but to mutilate, may carry their habits with them to the hospital wards. Many of these poor people, too, read the newspapers, and are struck by learning that in other lands the Sisters are driven out of the hospitals, the religious symbols are torn down, and the wards are named Salle Gambetta, or Magendie, instead of Saint Mary or Saint Francis, as they were formerly called—for the great charitable institutions with which the world abounds were founded and had means left for their support by men who were more full of human pity and charity than of love of science, and thought more of the relief of suffering than of the acquisition of medical facts.

There have been published, too, in journals and works of undeniable authority, reports of experiments which, to say the least, are quite intimidating. In the *Lancet*, for example, for 1875, are indisputable cases of horrible experiments with

the virus of the foulest of diseases, recorded in Henry Lee's *Hunterian Lectures on Syphilis*. In Ringer's *Hand-book of Therapeutics*, the results of painful and even dangerous experiments with poisonous drugs, administered with no other motive than that of a purely scientific curiosity, on men, women, and children, are freely cited. In a medical journal of this city,* some few years ago, were published some experiments on the functions of the lobes of the brain, in which needles were passed at various points into the dura mater and into the brain of a poor woman, admitted into the ward of a hospital called *The Good Samaritan*. In observation 3, we read: "When communication was made with the needles, her countenance exhibited great distress, and she began to cry. Very soon the left hand was extended as if in the act of taking hold of some object in front of her; the arm presently was agitated with clonic spasms; her eyes became fixed, with pupils widely dilated; lips were blue, and she frothed at the mouth; her breathing became stertorous; she lost consciousness, and was violently convulsed on the left side. The convulsion lasted five minutes, and was succeeded by coma. She returned to consciousness in twenty minutes from the beginning of the attack, and complained of some weakness and vertigo."

Observation 4 was the same as the preceding, except that the strength of the current was not sufficient to produce the epileptiform attack.

In observation 5, the proposed experiment was abandoned; Mary was in too desperate a condition. "The next day Mary was decidedly worse. She remained in bed, was stupid and incoherent. In the evening she had a convulsive seizure, lasting about five minutes, confined to the right side. After this attack she lapsed into profound unconsciousness, and was found to be completely paralyzed on the right side," etc., etc.

At the autopsy the track of the needles in the brain could be distinctly traced on both sides: on the left, the needle had penetrated a depth of one inch, on the right, one and a half inches; the track being marked by a line of diffluent cerebral matter.

The reporter in this case says it seems to him most desirable to present the facts as he observed them, without comment, and we have no wish ourselves to make any, except to say that there are comparatively few in the lower classes of society who would care to be exposed to such practices.

Sylvius, in his preface to the *School of Salernum*, says: *Si dare vitam proprium munus Dei est, certè datam tueri, et jam oppressam pene restaurare, aut fugientem retinere, quod medicorum est, Deo proximum fateamur oportet.*

A modern man of science, like the *insipiens* of ancient days, is generally believed "to say in his heart, there is no God,"* so that whether or no He be nigh to Him may not cost him a thought; but those who do believe in Him, must be excused for an unwillingness to entrust themselves to any one who regards mind as a mere outbreak of matter, and man a mere animal developed from irrational stock.

We believe that we have given here the principal reason why so many show dislike to entrusting themselves in institutions founded and maintained in pure benevolence and kindness towards the sick and suffering, and where they certainly can and, moreover, generally do, receive the most skillful and careful attention.

THE DIFFICULTIES THAT BESET SANITARIANS.

One of the most remarkable illustrations of the survival of the superstitions of the "dark ages," and one that seems almost incredible in the light of the nineteenth century, comes to us from Spain. We read that in the cholera-ravaged districts of that fair country, the sanitary officials, while endeavoring to perform their duties of disinfection, etc., were set upon by infuriated mobs and driven from their labor, the ignorant populace preferring to rely *solely* upon prayers for the staying of the epidemic. This action has two

* See the American Journal of the Medical Sciences for April, 1874.

* There are other resemblances between such men and the *insipiens* (or *agnostic*) of olden time, for we read, "*corrupti sunt, et abominabiles facti sunt in studiis suis.*

strong parallels; that of the masses in Naples last year who interfered, absolutely interfered (think of it), with the physicians in their ministrations to those sick of cholera, and that of some ignorant colored persons in Washington, who recently interfered forcibly with the performance of a necessary surgical operation upon one of their race, for the alleged (and no doubt honestly conceived) opinion that the design of the doctors was to kill the patient, and, we might add, to make cod-liver oil of the corpse, since this is a favorite superstition among the Washington darkies.

We do not mean to belittle the efficacy of prayer—far from it; but we do unhesitatingly assert that intelligent clergymen of all denominations freely admit and teach that prayers and sanitation should go hand-in-hand; neither should be relied upon to the exclusion of the other.

Again, in addition to this superstition, we have the ignorance, or duplicity, or carelessness of presumably intelligent men to contend with. This fact is well illustrated in the following extract from the Cairo correspondent of the *Brit. Med. Jour.*, who says:

"The following story illustrates the impossibility of any general sanitary reform as long as the capitulations practically exempt Europeans from the regulations which apply to natives. A short time ago Surgeon-Major Green was informed by a lady that she had reason to believe there existed a case of small-pox at the laundry where her clothes were washed. The sanitary sub-director immediately proceeded to the house in question, in company with the lady, and found, as she said, a young man with small-pox, exhibiting a well-marked pustular symptom of several days' duration. In the very room where he lay was some of the linen taken in to wash. The patient had been attended by two medical men, the one an Austrian, the other a German subject. They had given the friends of the patient a written statement that he was suffering from 'wind' pox (*sic*), and accordingly led them to believe that there was no need for precautions to be taken. This paper was shown to Surgeon-Major Green. The latter obtained a confirmatory opinion as to the case being one of true variola, and then wrote to the attending medical men, requesting them to come to him at the Sanitary Directorate, and explain their conduct. They went. The Austrian subject simply excused himself on the ground that the case was modified small-pox. The German subject, who is a medical man of considerable practice and established position in Cairo, disputed the right of the Sanitary Directorate to interfere with him, and took the matter to his consul. Surgeon-Major Green blamed them for misleading the patient as to his true condition, and not advising the friends to take proper precautions. The German Consul wrote to Nubar Pasha, accusing Surgeon-Major Green of "furtively" entering the house of the German's patient, and interfering with him in the treatment of the case. He disputed his right to interfere with a German subject in any manner whatever, and asked that reparation may be made for the insult endured by his *protégé*. Surgeon-Major Green has replied, pointing out the great danger that would ensue to the public health if medical men were allowed to act in such an unprincipled way, and asking that the case may be referred to the German Medical Faculty for arbitration. There the matter rests for the present."

It required the terrible lesson taught by the Plymouth epidemic to give us a State Board of Health, and it will require a frightful visitation of cholera to cause our masses to realize the importance and necessity of sanitary science.

Enough of a decisive nature has been already accomplished by the apostles of hygiene to entitle this science to a high place in the estimation of the people, but, notwithstanding all this, the great obstacle of non-coöperation of the people still stands in the way of sanitarians.

Notes and Comments.

Case of a Hermaphrodite Aged Nine Years, with the External Appearance of a Female, in Whom Both Testicles were Removed from the Labia Majora.

Dr. George Buchanan thus writes in the *London Med. Times*, February 14, 1885:

Before giving you the particulars of this extraordinary case, I may recall to your mind the classification of hermaphrodites, and although it may be open to some criticism, I shall adopt that contained in Sir James Simpson's paper in the "Cyclopædia of Anatomy and Physiology," viz.: into spurious and true.

The spurious comprehend those in which mal-

formations of organs of one sex make them have somewhat the appearance of those of the opposite sex; the true, those in which there exist in the same individual some of the organs of the two opposite sexes. Without entering into any detail, I shall simply give the following list founded on cases actually recorded, viz:

Spurious hermaphrodites. Females have been mistaken for men in consequence of excessive development of the clitoris; also long continued prolapsus uteri. Males have been mistaken for females in consequence of extraversion of the bladder; of adhesion of the penis to the scrotum; of hypospadias.

True hermaphrodites have been divided into *lateral*, with an ovary on one side and a testicle on the other; *transverse*, *i. e.*, with the external organs male and the internal female, or *vice versa*, the external organs female and the internal male; and *vertical* with male and female organs on the same side in the same plane.

The case I have to bring before you is one of the transverse kind. I shall shortly relate the circumstances as they occurred.

Christina ——, aged nine years, was admitted into my ward in the Western Infirmary, complaining of uneasiness in the region of the pudendum, but without any history of injury.

On examination, I found the right labium somewhat swollen, and evidently containing a small movable body the size of a Spanish nut. It was connected to the inguinal region by a small process, and ont racing that up I could feel that it emerged from the external abdominal ring. Precisely the same state of affairs existed on the left side, but the little body was further down, and there was a distinct external abdominal ring, so large as to admit the point of the little finger.

I had at first great doubts as to the nature of the case, conceiving it possible that it might be one of double hernial sac, each containing an ovary. But that seemed so improbable that the other alternative suggested itself, that it might be a hermaphrodite, externally a female, with testicles in the labia.

The child had the hair cropped short; it was of a sandy red color; the whole aspect gave one the idea more of a boy than a girl, and a stranger approaching the bed would naturally suppose it was a boy.

But the external organs were female; the vagina, nymphæ, clitoris, meatus, and hymen were normal—just the appearance they would have in a girl of nine years.

I was in great doubt, so I got Professors Leishman and Cleland to examine the parts along with me. Their impression was that the little bodies were ovaries, but how they had got into the labia it was difficult to understand.

After further observation, I became certain they were testicles; for on touching the skin on the front of the thigh they were immediately drawn up close to the inguinal ring, thus proving the existence of a cremaster muscle.

I therefore determined to excise one of the bodies, being satisfied that in either case it was justifiable and necessary. If it proved to be an ovary, the operation would remove it from a situation where at the period of menstruation nothing but discomfort and trouble could be looked for. If a testicle, it was even more necessary; for the approach of puberty in a male, with all the external organs of a female, would have been attended with most complicated results. Morally as well as physically it was prudent to unsex the person, so far as that can be done by removing the most characteristic sexual organs.

On the 24th of November, 1884, the patient was put under the influence of chloroform, and I cut down into the left labium in exactly the same way as is done for the radical cure of hernia. The testicle was found in an unclosed tunica vaginalis, and was removed. The pillars of the ring being apart, two silver wire sutures were introduced, and the aperture closed.

The testicle proved to be perfectly normal. Professor Cleland was present, and examined it along with me. It was healthy and well developed, and rather larger than one of that age.

The wound rapidly healed.

Being quite convinced of the propriety of removing the other, this was done in the same way a few weeks after, and the parts are now quite healed.

During the time the patient was under the influence of chloroform, a complete examination of the external organs was made. Now we could see more definitely the perfectly normal condition of the clitoris, nymphæ, and meatus. The vagina extended the usual depth, but when the finger reached the extremity, instead of the os uteri there was a vertical septum, on each side of which was a little *cul de sac*, like a very small thimble. The only other condition dissimilar to the normal female organs was the existence of a narrow slit at each side of the meatus, large enough to admit the point of a probe.

The little *culs de sac* are probably the analogues of the cornua uteri; the little slits probably the orifices of the ejaculatory ducts.

The patient was brought in, and the members had the opportunity of observing the external organs. The testicles, which had been dissected by Professor Cleland, and preserved in spirit, were also shown.

The Treatment of Biliary Colic.

The *Dublin Journal of Medical Science* tells us that among the other purposes for which Kussmaul's procedure of washing out the stomach has been suggested, is biliary colic, due to impacted gall-stones. At a recent meeting of the Berlin Medical Society, Rosenthal reported two cases treated in this manner. One was that of a woman of thirty-three, who had been six months under his care with successive attacks of biliary colic, for which all the usual measures had been resorted to, morphine alone giving her relief. He then washed out the stomach, with a view to obtaining the sedative effect to which attention had already been called by Senator. As an apparent consequence, the vomiting, which had been troublesome, ceased. She returned almost daily to have the operation repeated, and on the fourteenth day she brought with her two gall-stones, each about as large as a hazel-nut. Since then she has had no recurrence of the symptoms. The second case was also that of a woman who suffered from very severe attacks of hepatic colic with obstinate vomiting, and after washing out her stomach for a few days, not only did the vomiting cease, but the stones were also passed. Rosenthal did not undertake to explain the *rationale* of this treatment.

Lemons in Bright's Disease.

Before the Medical Society of Otsego County, April 21, 1885, this subject was discussed. It was shown that patients who have the symptoms of the disease strongly marked not only in many instances live for a long time, but make an apparent recovery.

Dr. H. W. Boorn (A. M. C., '66,) cited the case of a man who had, as he thought, all symptoms of the disease last autumn, his urine under heat showing that it consisted almost wholly of albumen. This patient having a desire to eat lemons, began eating them to an extravagant extent, eating as many as six or eight a day. "At the present time he is about his business as a small peddler, and his urine examined this day shows no albumen whatever."

Tannate of Cannabine.

In the *Therapeutic Gazette*, Dr. H. C. Wood says that he has to thank Mr. Merck, of Darmstadt, for some grammes of the tannate of cannabine, whose alleged hypnotic virtues he has thus been able to test. It is evident from the dose which is habitually given of this drug that it does not represent the activity of the cannabis indica as has been claimed for it. An active preparation of the cannabis is efficient in doses of a fraction of a grain. He has given of the tannate to a number of patients twenty grains a day, and has not been able to perceive any distinct effect other than in some cases slight drowsiness, and in one or two cases of chorea an apparent lessening of the movements. The powder is readily taken in doses of ten grains; and, possibly, given in very large amount might have some feeble soporific influence. No disturbance of the stomach or bowels or other symptoms were produced by it.

Special Report.

OPHTHALMOLOGY.—NO. XIX.

BY CHAS. S. TURNBULL, M. D.,

Of Philadelphia.

On Cocaine and its Use in Ophthalmic and General Surgery.

By H. KNAPP, M. D., Arch. Ophthal., Vol. xii., No. 384.

"No modern remedy has been received by the profession with such general enthusiasm, none has become so rapidly popular, and scarcely any one has shown so extensive a field of useful application as cocaine, the local anæsthetic recently introduced by Dr. C. Koller, of Vienna. I am convinced that it will not only continue to prove as valuable as it has hitherto been found, but that its properties will be the subject of numerous scientific researhes and clinical observations all over the globe for many years to come." * * * "I have cauterized the cornea with the nitrate of silver stick until it became milky-white. During all this the animals did not move. The last experiment convinced me that the anæsthetic involved the whole thickness of the cornea, and did not affect the surface only. But if I incised the cornea, the animals manifested intense pain when the aqueous humor escaped and the iris prolapsed." * * * * * * * * "The pupil is never *ad maximum* dilated, responds promptly to light and convergence during the whole time, and for that reason the sensation of dazzling, connected with atropine mydriasis, is either totally absent or only slightly pronounced.

"From the beginning I have thought that therapeutically cocaine might be used in two directions: First, as a *narcotic in painful affections of the*

eye, and secondly, as an *anæsthetic in operations on the eye*. In regard to the first category, I have expected a good deal of benefit from its action in *diseases* of the *cornea* and *conjunctiva*, accompanied by *pain* and *photophobia*. I have used cocaine in a great number of patients suffering from lymphatic (phlyctenular) conjunctivitis, with eruptions and ulcers of the cornea, and a two per cent. solution in one patient affected with frenulum vasculare (from successive phlyctenulæ). All patients thus treated have said that a few minutes after the instillations they have *felt* materially better, pain and photophobia having considerably diminished. With the same unanimity, however, they have complained that two or three hours after the instillation pain and photophobia have returned. In regard to the second category, cocaine does excellent service in the *removal of foreign bodies from and out of the cornea*. With the same good result cocaine has been used in a case of pterygium, cauterization of corneal ulcers, staphyloma operation, extraction of cataract, iridectomies, enucleation, etc., etc."

Höltzke. *Experimental Investigations on the Pressure in the Anterior Chamber*. Arch. f. Ophth., vol. xxix., 2.

According to Höltzke, eserine can produce a marked increase of pressure in the anterior chamber, but the myosis caused by it not only neutralizes this increase, but even diminishes the pressure below the physiological mean.

Atropine does not directly increase the pressure, but indirectly, by dilating the pupil.

Letranc. *Contribution à l' étude de la lumiere et de la chaleur considérée comme causes de maladies des yeux chez les verriers principalement*. These de Paris, 1883.

He concludes from his investigations in glass manufactories that intense light and heat are not injurious to healthy eyes ; only to previously diseased ones. Adaptation and the kind of flames (in melting glass, yellow) play an important part.

Moura. *Brazil, La tension intraoculaire dans les races blanche-métisse, noire, et de indigiéne*. Ann. d'Ocul., March and April, 1883.

He finds that under physiological conditions the intraocular pressure is much higher in negroes than in whites. They are therefore three to four times more predisposed to glaucoma. The field of color perception is greater in natives than in whites.

Gillet de Grandmont. *De l' action des courants électriques continue appliqués au voisinage du cerveau et des résultats qu' ils produissent en particulier dans l'œil*. Gaz. d'Ophth., April and May, 1883.

He has investigated the action of the descending constant current on the vascular system, the subject of experiment being the frog's tongue spread under the microscope. During the action of the current the arteries enlarged and the blood flowed perceptibly faster.

Voltolini. *The Electro-magnet in Ophthalmology*. Deutsche Med. Wochenschr., 1883, No. 20.

Voltolini first makes the chip of iron magnetic by applying a very powerful electro-magnet to the eye, and extracts it with a smaller one. If the strong magnet can move the foreign body in the eye, an incision only is made, and the chip drawn to the surface with the maguet.

Zahl. *The Usefulness of the Magnet in Removing Chips of Iron from the Interior of the Globe, and Report of a Case*. Inaug. Diss., Greifswald, 1883.

In thirty cases the electro-magnet was used to the greatest advantage ; in three, blindness ensued. In ten cases the globe had to be enucleated ; either the operation had failed, or because the eyeball became inflamed or had shrunken after the removal of the chip of steel.

Stricker. *The Light-perceiving Apparatus of the Retina*. Sitzug. der K. K. Ges. d. Ærzte in Wien, March 30, 1883. Wiener Med. Presse, No. 14.

Stricker found a very peculiar condition of things in a tiger and leopard. The layer of rods and cones was entirely wanting, its place being taken by a broad granular layer. The animals had seen well during life.

Emery Jones. *The Effect of the Electric Light on the Eye*. Ophth. Rev., vol. ii., April 18.

Observed inflammation of the eye due to electric light.

Moyne. On the examination of *The Acuteness of Vision and Color-sense in Railway Employees and Sailors*. Annal d. Ottal., vol. xiii., Part 1.

Did not discover a single case of congenital Daltonism amongst 150 railroad employees, while in the same men he discovered ten cases of acquired Daltonism after the abuse of alcohol and tobacco.

Techerning's results—Studies on *The Etiology of Myopia*. Graefe's Arch., Band. xxix., 1, page 201—are based upon the examination of 9,567 persons, 7,523 belonging to the military recruiting contingent, and 2,044 being observed at Hansen's clinique in Copenhagen. In his opinion there are three varieties of myopia, the first of which, the weakest degree, is either congenital or acquired up to the age of twenty-five. For this form there does not appear to be any special cause, neither close work of the eyes, nor diseases within the eye, although there may an hereditary dispos-

tion. Vision is generally good, and the fundus of the eye is either entirely normal or exhibits a very small crescent. The second form is the re-result of close work, and is especially frequent amongst the educated classes. It very rarely reaches 9 D. (4½″), and averages about 4 D. (9½″) The third form, which fortunately for the human race is rare, must be looked upon as a genuine disease. In this class are included those excessive degrees of myopia, higher than 9 D., (4½″), which are scattered with great uniformity amongst all classes of people, without any especial regard to their occupation. These form at the highest about one per cent. of the population This type depends evidently and always upon elongation of the ocular axis; those extremely large myopic eyes occasionally observed during autopsies, belong to this category. In this class heredity plays a rôle, although perhaps less than in other forms of myopia. As a rule, it appears at a very early age, and advances so rapidly that by the time the patient has reached his twenty-fifth year 9 D. (4½″) has been passed. It is a disease *sui generis*. Myopia caused by reading is benignant, and appears to be nothing but an accommodation of the eye to its work. It is extremely doubtful whether any dangerous myopia can develop itself from this latter class.

Reich, M. Alterations in *the refraction of eighty-five scholars observed during a period of six years*. V. Graefe's Archiv, Band xxix., 2, page 73.

Reisch had examined 145 high-school scholars some six years previously, and now had an opportunity of re-examining eighty-eight of them. While, in 1876, the emmetropes composed thirty-five per cent., the myopes twenty-five per cent., and hypermetropes thirty-six per cent. of the whole, he now discovered forty-three per cent. of emmetropes, fifty per cent. of myopes, and three and four-tenths per cent. of hypermetropes. The remainder suffered from amblyopia. The most notable points were that out of thirty-two cases of hypermetropia twelve had become myopic; of thirty-two emmetropes fourteen had become myopic, while of twenty-two myopics, eighteen had become more strongly myopic. The ophthalmoscopic examination had shown twenty-four per cent. of crescent six years ago, while at the re-examination the percentage had increased to sixty.

Mittasch. *The Syphilitic Diseases of the Eyelids*. Inaug. Dissert., Würzburg, 1883.

Mittasch describes the syphilitic affections of the eyelids. He first mentions the syphilitic initial sclerosis. Indurated chancre of the lids is of very rare occurrence. Its favorite locality is at the inner canthus. The infecting ulcer either arises from the outer skin of the eyelids, and subsequently attacks the lachrymal caruncle and plica semilunaris, or vice versa. Amongst the secondary syphilitic affections of the skin of the lids, the slighter forms of the exanthema generally form a partial symptom of the general eruption upon the skin.

Bock. *The Transplantation of the Skin and Mucous Membranes in Ophthalmic Surgery*, Vienna, 1884.

Bock publishes the results which have been obtained in Stellwag's clinique in cases of transplantation of skin flaps without a pedicle. This operation was performed in every case in which the aim of the surgeon was to compensate for losses of substance in the adnexa of the eye or to cure deformities, when the simple shifting of flaps did not suffice. In doing this, both external skin-flaps and flaps of mucous membrane were transplanted. The transplantation was performed after the extirpation of neoplasms on the lids in cases of malformation of the lids, but chiefly in cicatricial ectropium, as well as in cases of symblepharon and cicatrices of the conjunctiva. In almost every case the skin was taken from the left arm of the patient, but as little as possible of the subcutaneous tissue left with it. The flaps were divided into small pieces, and several were used to cover the defect, because they could be much better adapted to the new surfaces, and accommodated themselves better to the form of the loss of substance. Defects in the mucous membrane were compensated for by bits of mucous membrane from the vagina. The latter were, however, invariably transplanted in toto, since small pieces were easily and rapidly thrown off from the conjunctival sac, or, at least, completely disarranged by the nipping together of the eyelids.

Bock. *A Case of Sarcoma of the Lachrymal Gland*. Wiener Med. Presse, 1883, No. 33.

Bock observed on the left upper eyelid of a healthy man a tumor which extended from the middle orbital margin to the external canthus. The tumor was not connected with the globe, and could be moved about independent of the lids. On everting the lid, the growth protruded from the upper conjunctival fold in the shape of a bright red mass as large as a bean. It was extirpated, and under the microscope was discovered to be a small-cell, round-cell sarcoma, together with remnants of infiltrated tissue of the lachrymal gland.

Harlan. *Sarcoma of the Lachrymal Gland*. Transactions Amer. Oph. Soc., 1882.

Harlan has also seen a tumor of the lachrymal gland as large as a hen's egg. This, also, proved to be a spindle-cell sarcoma.

Alterations of the semi-lunar fold of the conjunctiva and of the adjacent lachrymal caruncle have hitherto been rarely mentioned.

Eversbusch. *On Some Alterations in the Plica Semilunaris.* Munich, 1883.

Eversbusch describes a cartilaginous formation and an angioma of the plica semilunaris, as well as hypertrophy of the same, which depended upon syphilitic infection.

Hoadley, Garb. *Hemorrhage from the Nose and Lachrymal Canal.* British Med. Journal, April 14, 1883.

Saw a case of epistaxis demanding an anterior tampon, after violent coughing, by a man who had heart disease. Two hours later the blood escaped from the right canaliculus.

Hock. *Traumatic Cyst in the Lachrymal Region—Extirpation—Cure.* Report of his private clinique, Vienna, 1883, p. 15.

Removed from the region of the right lachrymal gland a cyst as large as a walnut, which evidently originated from a blow from a horse's hoof, which disfigured the entire neighborhood, and produced persistent lachrymation.

Paralysie Simultanée des deux Moteurs Oculaires Communs par Nicotisme. Rec. de' Ophth., tom. iii., 6, p. 309.

A man who had smoked excessively for a long time, and of late had drank a large amount of alcohol, consulted Fontan, who discovered that suddenly one morning, just after arising, the patient had perceived a paralysis of the rectus internus of the right eye, and in the left eye a paralysis of the levator palpebræ, rectus superior, internus inferior, and obliquus inferior. The nerves of the sphincter iridis did not appear to be paralyzed on either side, but they were partially irritated, for the pupils were remarkably contracted when the patient looked at the light, while if a shadow was thrown over them they did not enlarge to any great extent. A diminution in the amount of tobacco smoked was followed by a decided improvement. Fontan expresses the opinion that the chief cause of the paralysis was the abuse of tobacco, while to the alcohol he attributes an inferior influence.

"Is contraction of the pupil, which has been repeatedly noticed without any explanation (Claude Bernard, Carle) in paralysis of the third pair, a satisfactory symptom in the diagnosis of nicotine poisoning? I believe that we should pay considerable attention to this point, and that new facts will satisfactorily solve this interesting question."

Westphal's Investigations, (*On Total Paralysis of the Ocular Muscles in the Demented*, Fahreszeitung des Vereins der Irrenærzte, Berlin, 1883,) demonstrate in the insane, and especially in paralytics, a progressive form of paralysis which attacks all of the ocular muscles, and finally leads to total fixation of the globe. The ophthalmoscope generally shows atropic degeneration of the optic papilla. Disturbances are also noticed in other motor nerves.

Gutmann, (*Diabetic Abducens—Paralysis.* C. F. A., 1883, p. 209), publishes a case of paralysis of the abducens in a diabetic patient. The symptom disappeared entirely after visiting the Carlsbad Springs.

(*To be continued.*)

CORRESPONDENCE.

An Almost Painless Mode of Introducing a Catheter where there is a Hyperæsthetic Condition of the Urethra.

EDS. MED. AND SURG. REPORTER:—

This consists in introducing the nozzle of an ordinary male urethral syringe (previously filled with water as warm as the patient can bear) into a soft catheter, and injecting the water slowly as the catheter is gently passed along the urethral canal.

If the bladder is not entered by the time the first syringeful is exhausted, refill the syringe and proceed as before.

You will find that the water will regurgitate between the catheter and urethral wall till the catheter has reached the prostatic portion, thus lessening the danger of injecting too much water into the bladder.

My experience with this method is very limited, yet it has proved very successful in the few cases I have had, and as I have never seen an account of it in any medical works or journals, I submit it to the profession for a trial and report of its success. The following is a case showing its value:

J., æt. 20, male, of nervous temperament, suffering from cystitis (the result of a gonorrhœa of several months' standing), which was attended with all the suffering characteristic of this trouble, and with an abundance of pus, mucus, blood, and heavy deposit of the phosphates in his urine.

He had to micturate every twenty or thirty minutes, both day and night, and had been so for two months, so I concluded to wash out his bladder; but on attempting to introduce the catheter, (which was a soft rubber one), I found the pain so intense as to cause spasm of the sphincter vesicæ, thus rendering all efforts at entering the bladder fruitless. The thought then occurred to me, that by injecting warm water and putting the urethra slightly on the stretch, I could pass the catheter; so I procured the syringe and again started the catheter, keeping a steady flow of water

playing on the urethra, and very much to his comfort and my satisfaction, I succeeded in entering his bladder without causing, as he stated, the least pain. JNO. A. STAMPS, M. D.,
Wallaceburg, Ark.

A Twin in Bad Company.

EDS. MED. AND SURG. REPORTER:—

In March, 1883, I was called to attend in confinement Mrs. Y. I was at the bedside probably two or three hours. The presentation was good (first) and the labor apparently normal. When I asked the lady if she had felt *motion* since her labor began, she replied that she had, and that very *distinctly*. I generally ask this question (I presume the doctors all do), so that in case I get a dead baby I may, if possible, have some evidence that the child was dead before I was called to the case. I was very particular on this occasion about this matter, because it was their first child, and they had a morbid dread lest it should be still-born. When the child arrived, I found it limp, motionless, and silent as is Julius Cæsar to-day. On taking it from under the bed-clothes, and to the light, I found it rather smaller than it should be, very dark in color, and somewhat putrid, the skin being readily detached by slight pressure with the fingers. The mother wanted me to explain how she could have been so terribly deceived when she thought she felt motion. I promptly "gave it up." On attempting to remove the placenta I found *another child* in utero, which was born a few minutes later, and was alive and healthy.

This little individual, then, had completed the latter part of the journey of fœtal life with a human carcass for a bosom friend and traveling companion. When I thought how tenaciously he had clung to life's fitful spark, I admired his pluck, and wished that *always* hereafter if the child was dead-born, I might still find a *reserve* child in utero. WALTER H. PARCELS, M. D.
Lewistown, Pa.

NEWS AND MISCELLANY.

International Sanitary Conference.

We note the following special report from the *Brit. Med. Jour.*, June 13, 1885:

The report of the sub-committee appointed to consider the best methods of disinfection in cholera, and consisting of Drs. Koch, Sternberg, Thorne Thorne, Proust, Eck, Semmola, and Von Hofmann, was laid before the Technical Committee at the sitting of June 2. It is thus worded:

The sub-committee recommends as methods of disinfection:

1. Steam at 100° C.
2. Carbolic acid and chloride of lime.
3. Ventilation.

Of the carbolic acid and chloride of lime, two solutions are to be used: *a*. the weak, containing two per cent. of carbolic acid and one per cent. of chloride of lime; *b*. the strong, containing five per cent. of carbolic acid and four per cent. of chloride of lime. They are to be applied as follows:

1. For personal disinfection, by washing and bathing with the weak solutions.

2. For disinfection of linen, clothes, bedding, etc., if not destroyed—(*a*) by passing steam through them for an hour, (*b*) by boiling them for thirty minutes, (*c*) by immersion for twenty-four hours in one of the weak solutions, (*d*) by ventilation for three or four weeks, but only in cases in which none of the other methods are applicable. Leather articles—such as portmanteaux, handbags, etc.,—if not destroyed, are to be washed several times with one of the weak solutions.

3. For vomited matters and fæcal evacuations, the strong solutions are to be used. Recently-soiled articles of linen, clothing, and bedding, if not at once subjected to steam at 100° C., are to be immersed for four hours in one of the strong solutions.

4. There must be no washing of corpses. Bodies are to be wrapped up in sheets saturated with one of the strong solutions, and at once put in coffins.

5. Disinfection of goods, letters, and postal packages is superfluous.

6. For the disinfection of ships during the passage: The deck and class where the case or suspected case occurred, and the walls of the cabin or bunk, are to be washed, at least twice, with one of the weak solutions, and then thoroughly ventilated; while the water-closets are to be washed, at least twice daily, with one of the strong solutions.

7. If the drinking-water be suspected, it must be boiled before being used; and if it has stood twenty-four hours after the first boiling, it must be reboiled.

8. In hospitals on land, the walls are to be washed with one of the weak solutions, then the wards ventilated, and finally whitewashed, and the wards used for the reception of cholera cases are to be as far off as practicable from the ordinary ones. The closets in such hospitals are to be cleansed twice daily with a quantity of one of the stronger solutions equal in amount to that of the evacuations passing through them.

9. The clothes of the attendants are not to be taken out of the hospital, and must be regularly disinfected; and the attendants are to use one of the weak solutions for personal ablution.

It was also decided to add to those recommendations another, to the effect that all packet-boats from infected ports should have a steam-disinfecting apparatus on board.

In the discussion which followed the reading of the sub-committee's report, a number of the members took objection to the omission of various powerful disinfectants from the list recommended. The Dutch delegate, Dr. Ruysch, warmly insisted on the efficacy of corrosive sublimate, and one of the French delegates on that of sulphate of copper and sulphurous acid; whilst others maintained that no particular disinfectant was of any great utility, and that the Technical Committee should not, in the present state of knowledge, commit themselves to any definite recommendations. It having been pointed out by Dr. Koch and Dr. Sternberg that the report did not definitely exclude any one disinfectant, but was simply based on the necessity for naming simple, cheap, and readily transportable chemicals, not

too complicated nor too dangerously poisonous, Sir Joseph Fayrer moved the adoption of the report, and this was carried.

The sitting on June 3, which was occupied with the recommendations of the sub-committee on the measures to be taken on the arrival of suspected or infected vessels at their destination, and also on the measures to be taken when the disease was imported into the Mediterranean, unfortunately proved completely abortive, all the regulations of the sub-committee being rejected, and the matter referred for reconsideration to the members of that sub-committee, with the substitution of Drs. Koch and Baccelli for Sir Guyer Hunter and Dr. Sternberg, who had resigned.

The regulations proposed by the sub-committee on pilgrimages to Mecca came before the Technical Committee on June 4, and were discussed at great length, in spite of an attempt by Sir Joseph Fayrer and Dr. Ruysch, in the beginning of the sitting, to have them approved as a whole.

After some general recommendations as to the necessity of no passenger being permitted to embark for a pilgrimage to Mecca, who was unprovided with the necessary means; as to the presence on board of one or more surgeons appointed by the government of the country whence the pilgrimage proceeds; and as to all ships being held to be pilgrim ships which carried thirty or more pilgrims; power is given, in the report, to the surgeon to see to the disinfection of his ship before it leaves an infected port, and that quite apart from the inspection of the port health officer; to prevent any persons coming on board who are ill, or who he suspects are ill with cholera; to rigorously reject all clothing and bedding which have been used for cholera patients; and to attend to the disinfection of such articles if proceeding from a cholera-infected district. The ship's surgeon and the port health officer are to have powers to prevent overcrowding. On steamboats the 'tween-decks must have at least nine feet of surface, or fifty-four cubic feet, and on sailing vessels, twelve feet of surface, or seventy-two cubic feet of space, for each pilgrim. During the passage from an infected port, the surgeon must enforce the same sanitary measures in pilgrim ships as already determined on for ordinary passenger boats, and, in general, all the measures adopted by the Indian Government relative to the embarkation and transport of pilgrims from Indian ports to the Red Sea are recommended for application by other countries whence pilgrimages set out. It is also proposed, after a rigorous sanitary inspection of such a pilgrim ship at a sanitary station before its entry into the Red Sea, and after the surgeon has certified that all the hygienic rules prescribed have been rigidly observed, and that no death, nor case, nor even suspected case, of cholera has occurred on board, and after this has been confirmed by the visit twice within twenty-four hours of the health officer at the sanitary stations, that the ship shall be permitted to proceed at once to Jeddah. Should cases, or even merely suspected cases, of cholera have occurred on board, the same measures would be taken for the pilgrim ships as were passed for infected passenger vessels carrying surgeons and entering the Red Sea; and although a longer than five days' observation of the isolated and segregated groups of passengers and crew was strenuously advocated, the period of five days was accepted as sufficient by the majority. At Jeddah another inspection will be made, and free *pratique* granted after twenty-four hours' observation, if the vessel have remained clean; but if cholera has broken out on board after the ship has entered the Red Sea, it is at once to be sent back to the sanitary station at the entrance, to be dealt with there according to the rules previously laid down. Exactly similar regulations are to apply to pilgrim ships, both from Egypt and the Mediterranean, and on the return voyage, as now passed for the Indian pilgrimages; but the exact spots for establishing the sanitary stations are left to the plenary conference.

The Committee then dealt with the measures to be adopted against suspected and infected vessels at the ports of arrival. For suspected vessels—that is, those from infected ports—after a careful sanitary inspection, during the daytime, by the health officer of the port, free *pratique* will be at once granted, should all the sanitary regulations prescribed have been observed both at the port of departure and during the passage, and provided the ship's surgeon show a clean bill of health, and the passage has lasted ten days; but twenty-four hours' observation will be enforced if the voyage have been shorter than ten days, to permit the disinfection on board of the dirty linen and clothes of passengers and crew. For infected vessels, the more radical measures recommended are landing and isolation of the sick; separation of the passengers and crew into as many small groups as possible; washing and disinfection of all articles of linen, clothing, and bedding; keeping under observation of each group for five days' time from the removal from amongst the members of the group of any case; and, in addition, the bathing of each person in one of the weak disinfecting solutions, and the providing him with freshly-washed linen just before he is permitted to depart.

For suspected vessels proceeding from an infected port in the Mediterranean, a somewhat modified set of rules was adopted; the passengers and crew being disembarked, at the ports of arrival, in a locality so constructed as to afford absolute security for their isolation and disinfection; and being subjected there to an observation of three or six days, according to whether the vessel did or did not carry a surgeon. The more irreconcilable members naturally opposed these resolutions, which were only adopted by feeble majorities. For infected ships from Mediterranean ports, it was resolved to recommend the same measures as for such vessels coming from infected ports elsewhere.

The final sitting at which any work was done by the Technical Committee was held on Saturday, June 6th, when the general proposals of the sub-committee on the measures to prevent cholera spreading by land were considered. Previously to their being so, however, the British and Indian delegates, by special request, showed how trustworthy and practical was the system which Great Britain relied on to protect her from epidemic invasion, instead of the quarantine, which she had abandoned.

Dr. Thorne Thorne, after alluding to the general

idea prevailing abroad, that Great Britain had given up the quarantine system simply from the selfish motive that her enormous commerce was too much hampered by it, pointed out that, since the date of the Vienna Conference, England alone had spent twenty-seven millions of pounds on the improvement of local sanitation, and that this enormous expenditure had been repaid her, not only in her having escaped from epidemic invasion by cholera, but in the great diminution of loss of life from such endemic diseases as depended on local unsanitary conditions, such as typhoid fever; and he maintained that this would not have been the case had she continued, like other nations, to trust to quarantine. It would be a bad day for England, should she ever come to think that a period of five days' observation could be of the same value to her as that improvement in local hygiene on which she now confidently relied to prevent a cholera epidemic from taking root on her soil.

Sir Joseph Fayrer urged that the same measures for the improvement of local sanitation, which had been so successful in Great Britain, when applied in the three great Indian presidencies, had much diminished the general mortality, as well as the special cholera death-rate, throughout our large dependency; and that there was no other cause to which the greater healthiness of India could be ascribed, as the seasonal conditions were unchanged.

Sir W. Guyer Hunter referred to similar information already placed before the members of the committee by him at previous meetings, and contrasted the efficacy of the system of local sanitation, which had done so much to check the disease in India, with the proved total uselessness of quarantine and sanitary *cordons*, as lately tried in Egypt.

The committee then passed most of the regulations submitted to it by the sub-committee to prevent the spread of the disease by land, some of which are certainly too general to be of the slightest value. Thus it is recommended:

1. That local sanitation be everywhere attended to, and the first cases isolated and disinfected, the means for doing so being prepared beforehand by the sanitary authorities.

2. That immediate notification be made to the proper authorities of every case, or suspected case, of cholera, and the nature of the disease be confirmed by competent medical men, and, in case of death, by necropsy.

3. That a regularly organized medical sanitary service be instituted in every country.

4. That the health officers of every country should have powers to communicate directly, without intermediaries, so as to agree upon, and at once adopt, the measures they deem urgent.

5. Particular attention is always to be given to the great through routes by which cholera is imported.

6. International express trains must be changed in passing from an infected into a non-infected country, and a surgeon must accompany every such train, to take the necessary steps in the event of any one falling ill with the disease. Every large station is required to have an isolated room for the reception of such cases.

Dr. T. Lewis showed that this article was unnecessary, as the construction of the great trunk railways in India had not changed the lines on which cholera traveled in that country, nor increased the rapidity of its movements.

7. Passenger-boats on large rivers are to be rigorously inspected, overcrowding is to be prevented, and a medical inspection is to be made of those disembarking at the principal points of call, where isolated quarters are to be kept ready for the provisional reception of cases of illness.

Some other regulations, of less importance, for preventing the spread of the disease by land were also sanctioned, and the committee agreed, at the same time, that the measures for the Caspian Sea and the Russian Asiatic frontier should be identical with those already passed for protection against importation by sea and land elsewhere.

On the motion of Dr. Sternberg, it was also determined to apply to yellow fever the measures thought requisite against cholera, and the committee wound up its labors by passing some common-place rules, which are not worth citing, for notifying the leading features of disease in each country by special sanitary bulletins, and communicating to the separate governments, by telegraph and otherwise, the particulars of the appearance and extension of any contagious malady —a work performed for the public, in Great Britain and America at any rate, by their enterprising newspapers. Sir Joseph Fayrer having moved that Dr. Moleschott, as president, should report the results arrived at by the Technical Committee to Plenary Conference, and the usual votes of thanks having been agreed to, the members separated, to enjoy a few days' well-earned rest, to be spent, at the invitation of the government, in visiting Naples and its neighborhood.

Collective Investigation in Russia.

A meeting of delegates from the different medical societies has been held in the Red Cross Hall, in St. Petersburg, for the purpose of organizing collective investigation in Russia. The question arose as to whether it would be better to establish an independent central committee in Russia, or to send the individual reports direct to the International Committee in London. The meeting unanimously decided in favor of the former alternative, on account of the difficulty of entering into an extensive correspondence in a foreign language. The meeting consequently resolved itself into the Collective Investigation Committee for Russia, and arranged to keep up communication with the English Committee. Professor Lesshaft and Dr. Monastyrski were chosen as secretaries. Dr. Rauchfuss presented a report upon the results already obtained, and which had been published in the form of two little books, one dealing with phthisis, the other with acute pneumonia. It was decided that the next subjects for collective investigation should be those proposed by the International Committee, and with the same tables of questions, namely, rachitis, calculus, typhus exanthematicus, acute rheumatism, and diseases of the age of school attendance.

Massachusetts State Medical Society.

At the one hundred and fourth meeting of this

society held June 9 and 10, the following papers were read: "The Pathogenesis of Certain Skin Affections," by Dr. George N. Tilden, of Boston. "Consanguineous Marrrages: Their Effect upon Offspring," by Dr. Charles F. Withington, of Roxbury. "Labor Complicated with Fibroids," by Dr. J. R. Chadwick. "The Climatic Treatment of Phthisis," by Dr. Harold Williams, of Boston. "How a Lesion of the Brain Results in that Disturbance of Consciousness known as Aphasia," by Dr. Morton H. Prince, of Boston. "The Relation of Insanity to Certain Nervous Affections," by Dr. Henry R. Stedman, of Roslindale. "Cremation in its Sanitary Aspects," by Dr. John O. Marble, of Worcester. "Diagnosis and Treatment of Occipito-posterior Positions," by Dr. William L. Richardson, of Boston. "The Influence of Ovariotomy on Surgery," by Dr. John Homans, of Boston. "Antiseptic Surgery," by Dr. Franklin K. Paddock, of Pittsfield.

A Terrible Epidemic of Cholera in India.

The *Indian Daily News*, under date of May, tells us that the intense heat has caused a terrible outbreak of cholera at Pegu.

Near Rangoon the natives employed on the railway works are dying by hundreds, and they cannot bury the corpses fast enough.

Three at a Birth.

The *Bangalore Post* says: "A correspondent informs us that a woman named Mooniamah, of the shepherd caste, living in Cubbon Patta, near Yelavanka Gate, Bangalore, gave birth to three children on Tuesday, the 29th of April, at 7 a. m., one of whom is a male and the two others females. They are all alive up to date (May 1)."

Items.

—Dr. Edward Cowles, Superintendent of the McLean Insane Asylum, at Somerville, Mass., is to give a course of lectures on Mental Diseases at Dartmouth Medical College next autumn.

—Three Parisian manufacturers, in order to make tomatoes appear redder than nature has made them, varnished them with a chemical compound, and called them "the best quality tomatoes." They have been condemned to pay a fine.

—At its last meeting the Paris Faculty of Medicine decided that the prize founded by M. Lacaze, of the value of 11,400 francs, and which is given every two years, will next be awarded in 1886, to the author of the best work on Phthisis and Typhoid Fever.

—Whenever a case of scrofulous disease was presented at his clinic, in the person of a child *whose father had been in the army*, the late Professor Gross, asking no further questions, would turn to the class with the single, but significant remark, "*Specific*, gentlemen!"—*Col. Med. Jour.*

—The report of the Society of Hygiene of Milan draws attention to the influence of old shoes as a means of propagating cholera. When a person treads a soil more or less damp in a locality infected, there is every chance of his conveying the germs in the manner described.

—News comes from Marseilles of a sad occurrence in the Saint Pierre Lunatic Asylum. A keeper put two patients each in a separate bath, left them, and went to breakfast. One of the lunatics got out of his bath, during the absence of the keeper, and turned on the tap of hot water into the bath of the other. When the keeper returned, he found that the unhappy creature had been scalded to death.

—A mixed commission of twenty-four persons, made up of physicians and pharmacists, has been constitued at Berlin with the object of taking steps to prevent the further extension of the patent medicine trade in that city. At the first meeting a resolution was moved to petition the chief board of police in Berlin (Konigliches Polizei Præsiduum) to follow the example set by corresponding boards in Frankfort-on-the-Main and Carlsruhe, in publishing from time to time in the daily papers popular instructive articles on the subject of patent medicines.

OBITUARY NOTICES.

EDWARD HARTSHORNE, M. D.

Dr. Edward Hartshorne died in this city, June 22, in the 68th year of his age. The cause of his death was Bright's disease. Dr. Hartshorne was born in this city May 14, 1818, was a son of Dr. Joseph Hartshorne, and was a leading practitioner of Philadelphia for nearly fifty years. He was a graduate of Princeton, and received his degree of M. D. from the University of Pennsylvania. He was connected with the Pennsylvania Hospital for the Insane as first assistant physician when that institution first opened. Dr. Hartshorne has been prominently identified with the management of the Episcopal Hospital. He was a large contributor to the various medical journals, and was the author of several of the annual reports of the Episcopal Hospital, and editor and annotator of various English medical text-books, among them "Taylor's Medical Jurisprudence." During the war he was actively engaged as acting assistant surgeon in the army, serving to some extent in the field, but most of the time as consulting surgeon in army hospitals in this city. He was a member of the American Philosophical Society, Academy of Natural Sciences, the Historical Society of Pennsylvania, and other kindred associations. He was a most active and useful member of the College of Physicians. He was also for a long period medical adviser and examiner to one of our leading insurance companies, and for some time was one of the Vice-Presidents of the Princeton Alumni Association of Philadelphia. The profession, in his death, sustains the loss of a good, true, and honorable man.

QUERIES AND REPLIES.

MESSRS. EDITORS:—

Dr. I. G. Cunningham, of Kittanning, Pa., can find t formula in MEDICAL AND SURGICAL REPORTER, vol. XXXV p. 82 (January 27, 1877); beyond that I cannot help him.

FOREIGN BODIES IN THE VAGINA.*

BY THEOPHILUS PARVIN, M. D.,
Of Philadelphia.

The vagina has been more frequently the receptacle of foreign bodies, than has any other cavity of the human organism, and the variety of these bodies has been greater.

Among those which have been voluntarily or accidentally introduced by the female herself, may be mentioned † hair-pins, toilet-pins, needle-cases, crochet-needles, pebbles, spools, a pepper-box, a cotton veil, sponges, the bobbin of a spinning-wheel, the reel of a sewing-machine, lead-pencils, jelly-moulds, pewter cups, the neck and shoulders of a corked vial, the cup of a drinking flask, the socket of a brass candlestick, and the head and bust of a china doll. In regard to the last foreign body referred to, the history ‡ of the case was briefly as follows: A mulatto girl, thirteen years of age, in June introduced a doll's head and bust in the vagina, and in the succeeding November first complained of the suffering its presence caused; she assured her mother that she had swallowed the doll—her name was probably Sapphira—and it was only when partially anæsthetized she confessed that she put it in her vagina; both the truth and the baby came out under the influence of chloroform.

The motives which have led women or girls to voluntarily place foreign bodies in the vagina have been many, though not as numerous as the cases. A purse of money has been put in the vagina for concealment; a sponge has been placed at the mouth of the womb just before coition, in order to prevent conception, and forgotten until many months after, when deterioration of health, offensive discharge and hemorrhages from the vagina, and pain, led to the suspicion, if not the diagnosis, of cancer. In some cases the foreign body has been pushed, in thoughtless play, into the mouth of the vagina—sent on a sort of exploring tour, just as children drop pebbles into a well, or throw them in a cave; while in others, a morbid desire for sympathy, or to attract attention, may have been the motive for its introduction. In some cases the foreign body has been put in the vagina to stop the monthly flow; in two instances, girls menstruating for the first time—ignorant, surprised, and fearful at the discharge of blood—sought to arrest it by putting a spool in the vagina. In some cases the voluntary introduction of these bodies can only be attributed to an insane freak, or an arbitrary and unreasoning exercise of will, just as we have given in one of Juvenal's Satires, an example of a mistress who has her slave causelessly whipped, declaring, if my Latin be not at fault, *Voluntas sit pro ratione.*

In many instances, the foreign body has been introduced purposely, but has been accidentally retained. Thus a girl* has used a needle to

*Read before the Philadelphia County Medical Society.

† Some in the list are taken from Briesky, "Die Krankheiten der Vagina," Billroth's "Handbuch der Frauenkrankheiten," while the authorities from which many of the others have been derived, will be mentioned in the course of the paper.

*Schmidt's Jahrbücher, 1870, p. 308.

make her menstruation freer, or a woman a hairpin to procure abortion, and the instrument escaped from her grasp.

In some cases, the foreign body has been used for therapeutic purposes, and broken or become detached in the vagina. Thus a woman,* while taking a vaginal injection, loses the nozzle of her syringe; a troublesome leucorrhœa leads her after two months to consult a physician, and the lost body is found in the vagina. There are several cases reported where glass vaginal syringes have broken while in use, and the fragments remained in the vagina. In one of my patients, a married lady who had suffered from vaginismus, spontaneous fracture of one of Sims' glass dilators occurred when it was in the vagina, greatly to her surprise and alarm.

The foreign body may have been forced into the vagina by sitting down on it, or by a fall. A school-girl, on taking her seat, does not observe that a pencil is erect on it—the head below, the point above—and the pencil is thrust into the vagina, its point penetrating the bladder.

Jansen, of Ostend,† has reported the case of a woman who had an ale-glass, two inches and a half in diameter and three in height, in her vagina, which she asserted had entered from her sitting on it.

Trapenard ‡ narrates the case of a woman sitting down on a faggot, being one of a pile; the faggot slipping, she falls some distance to the ground, and a triangular piece of glass and three spines of the acacia are forced into the vagina.

Salzer ‖ has narrated the case of a girl, thirteen years old, who, in a barn, slid down a pile of hay several feet high, and thrust into the vagina the iron part of a "heurupfer," which was lying concealed in the hay near the floor; the part of the instrument entering the vagina was nearly four inches long, and included the pointed end, and the projecting hook two inches in length.

But, according to Breisky,§ the most frequent accidental introduction of foreign bodies into the vagina has occurred in self-abuse—the body used escaping from the hand, and the party being unable to reach or to remove it.

The foreign body may be formed in the vagina. It is not uncommon to find in a patient who has suffered for some time from a large vesico-vaginal fistula, calculous concretions on the vaginal wall in the vicinity of the abnormal opening.

The foreign body may have come from an adjacent cavity. In case of recto-vaginal fistula, or where there is complete rupture of the perineum, fæces may be in the vagina. So, too, this accident has occurred even when the rupture of the perineum is only partial, as in the case of a young physician's wife, detailed by Breisky.*

Intestinal parasites may pass directly through a recto-vaginal fistula, or over the perineum, into the vagina. Thus there have been found in the latter oxyures, and the ascaris lumbricoides; but these are estrays, not true parasites of the female sexual organs.

Hausmann, in his work upon "Parasites of the Female Sexual Organs," states that in two instances he has found not only the ascaris lumbricoides in the vagina, but also the eggs; moreover, he has found in the vagina the eggs of the tænia solium. He mentions, too, a very curious fact, finding the itch insect in the vagina of a woman who had no external evidence of the presence of this parasite, the skin entirely free from disease, and he regards it as not at all improbable that under such circumstances the acarus was introduced in coition, for, according to Kuchenmeister, the acarus is in many cases abundantly reproduced upon the penis.

It may happen that a uterine fibroid undergoes calcareous degeneration, and some of the calcareous fragments, or the entire tumor, enter the vagina. Dr. Goodell † has given an illustration of the former, while Gaubius ‡ has furnished one of the latter occurrence. The patient of Gaubius was a virgin who had a uterine calculus so large that after it entered the vagina he could not remove it until he incised the vaginal mouth.

The greatest number of vaginal foreign bodies are tents, tampons, and pessaries—introduced for therapeutic purposes and left, through carelessness, or by accident, after these therapeutic purposes have been accomplished.

Uterine tents expelled from the uterus have remained injuriously in the vagina. Elliot ‖ has reported the case of a woman who, thirteen months after labor, suffered severe pain in the pelvis, and had such an offensive vaginal discharge that she thought she had "mortification of the womb." Upon examination, a tampon

was found in the vagina, which had been placed there just after her labor to stop hemorrhage.

The number of cases in which pessaries have remained an injurious time in the vagina is very great, and hardly a practitioner of five years' experience, who has not removed these foreign bodies. The late Dr. Atlee was accustomed to say in medical meetings, when the subject of pessaries was under discussion, that he had removed more pessaries than he had ever introduced; plainly it was impossible for him to accept Dr. Hodge's views of uterine pathology and therapeutics, as it was, for a time at least, for Dr. Hodge to accept Dr. Atlee's opinions and practice in the treatment of ovarian tumors. But apart from exclusive views, very many pessaries, unsuitable in form or size, or unnecessarily applied, or worn for too long a time, need to be removed. In reading some of the histories of removal of such foreign bodies, one is often struck with the great length of time which they have been worn before their injurious effects compelled seeking professional advice.

Sutton* removed a glass ball pessary that had been in the vagina fifteen years; Desormeaux and Dubois† mention a case where a silver-gilt pessary had remained for twenty-five years; Goodell removed a glass disk after thirty years' imprisonment; and Sabatier‡ had a patient who had worn her pessary forty years.

It does seem extraordinary that the vagina ever tolerates these foreign bodies so long a time, and yet a case reported by Pearse‖ is almost as remarkable; his patient had had a cotton veil in the vagina for twenty years. So, too, the case reported by Hanff is very remarkable. A nullip.,§ twenty years of age, had introduced into her vagina a coffee-cup, eighteen centimetres in circumference, and three and a half centimetres in diameter; it was removed entire after having been worn two years and a half.

So far, reference has been made to foreign bodies that have been introduced into the vagina by the patient herself, or by accident, or by the physician for therapeutic purposes. Foreign bodies have been put in the vagina, by men, from thoughtless or designed cruelty. A country girl had worn for years, before coming under the care of Dupuytren¶, a pomade-pot in the vagina; some brutal soldiers, after making her the unwilling victim of their lust, had thrust in this foreign body.

Among other of these abominable cruelties may be mentioned the introduction of the cone of a fir tree,** a turnip,†† a large crystal of sulphate of copper,‡‡ a wine-glass, etc. Günsberg‖‖ gives the case of an idiotic woman whose husband forced into her vagina a wine-glass, the stem of which was broken off; twenty-four hours after the cruelty was inflicted the wine-glass was removed, not without some laceration of the vagina, a forceps and Sims' speculum being used in the removal.

Instead of one foreign body there may be two or more. Schroeder§§ mentions a case under his care in which there were a cockchafer and a pomade-pot in the vagina; in Trapenard's case, previously stated, there were four foreign bodies; other illustrations are furnished by the fragments of a broken syringe, by some cases of vaginal calculi formed in consequence of a vesico-vaginal fistula, and by oxyures. But the largest number of foreign bodies is given in those instances where a needle-case has been introduced closed, and when in the vagina is opened, the needles then escaping; Grenier¶¶ has given two cases in which this occurred.

An interesting case has been given by Dr. Graham,*** where there was not only a foreign body in the vagina, but there was also one in the bladder—a spool in the former and a hair-pin in the latter; the spool had been in the vagina three years, and it was supposed that the hair-pin, which was bent in the form of a crook, had accidentally entered the urethra when the patient was attempting to remove the spool.

In considering the consequences of foreign bodies in the vagina, the least frequent will be referred to first.

There may be a serious wound of the vagina immediately resulting from the foreign body. In several of the cases where glass syringes have broken in the vagina, the latter has been wounded. Dr. Oldham††† has narrated a case in which death followed such wound; the death occurred the twelfth day, from internal hemorrhage.

†† Lancet, vol. i, 1870.

The foreign body may enter adjacent organs, or penetrate into neighboring tissues, partially or completely passing out of the vaginal canal. In a patient under the care of Dupuytren,* an ivory pessary, which she had worn for many years, had partly entered the bladder, and partly the rectum, so that it occupied not only the vagina, but the other cavities mentioned. The same condition was present in the case of Desormeaux and Dubois.†

In the case of the girl 15 years old, who had the vagina entered by a lead-pencil, the point penetrating the bladder, there was a calcareous deposit upon the part within the bladder. The removal, which was done six months after the injury was received, could not be accomplished until after an incision of the vesico vaginal wall was made.

Those cases in which the foreign body passes into the uterus, partially or completely, are most remarkable. The late Dr. Crowe, of Louisville, Ky., reported a case in which a Babcock's pessary had in part entered the womb; in the *New Orleans Medical and Surgical Journal*, 1883, a case is given in which the socket of a brass candlestick, three inches and one-fifth in length, four-fifths of an inch in diameter, and having a rim an inch and a half in diameter, was found in the uterus; this foreign body had first been introduced into the vagina.

Dr. Lever ‡ reported the following case: A woman while applying some ointment by means of a bone netting-needle, to allay irritation of the vagina, is disturbed by some one unexpectedly entering the room, and sits down suddenly; the instrument is forced into the vagina, and through the vaginal wall; in her efforts to remove it, it passes entirely out of the vagina and lies in an oblique direction to the right side of the latter. Nearly seven months after its introduction, this foreign body, which was six inches long, was removed, the removal being preceded by dividing it.

The foreign body remaining in the vagina may be encrusted by a mineral deposit. This deposit is composed of the triple phosphate and calcium salts. One of the most interesting specimens of such incrustation was presented, a few years ago, to the Philadelphia Pathological Society, by Dr. Getchell.‖ This calculus had been removed from the vagina of a girl nineteen years of age: it was three inches long, one inch and a quarter wide, three-eighths of an inch in thickness, and had been formed about a hair-pin as a nucleus. In the discussion following the presentation of the report and the specimen, the view taken by those Fellows who discussed the origin of such formations, was that they were usually derived from urinary salts. Such origin may be admitted as probable, though by no means proved, if there be a genito-urinary fistula; but if there be no such abnormal communication, how can urine enter the vagina, especially its upper part, where the foreign body is most frequently found? Breisky, in describing the effects of these foreign bodies in producing irritation, etc., of the vagina, states that the deposit comes from the stagnant secretions in the vagina, and he compares the foreign body thus incrusted to a foreign body in the bladder which serves as the nucleus for a vesical calculus.

A remarkable case of vaginal, uterine, and vesical calculus under the care of Prescott Hewett* occurred some years ago at St. George's Hospital. The patient had introduced into her vagina, eleven years before, the neck and shoulders of a large corked vial. The portion of the vial was covered with calcareous matter, and was in the vagina; the os uteri was blocked up with a mass which proved to be the cork similarly incrusted, and there was a calculus in the bladder; this patient had a small urinary fistula at the fundus of the bladder.

In some of the cases where perforation of the vesico-vaginal wall has occurred, the tissues gradually worn away by the foreign body, it has not been mentioned that any urine escaped from the vagina, and yet the portion of the foreign body remaining in the latter was covered with abundant incrustations; in one of these cases where the rectum and the bladder had each been entered by a part of the foreign body, so perfectly were the openings plugged by the body, it is expressly stated there was neither a urinary nor stercoral fistula.

Another consequence of the presence of a vaginal foreign body observed in some cases, is the production of abundant granulations from that part of the vaginal wall with which the body is in contact, so that after a time the latter is more or less completely imbedded, hidden from sight and touch, it may be. There may be associated with this a very marked stenosis of the vagina, the lower portion being of full size, while a small aperture leads to the upper part which contains the foreign body.

* Medical Times and Gazette, 1854.

In the case where a large piece of sulphate of copper was passed into the vagina, sloughing of the entire vaginal mucous membrane resulted. The victim was a girl seventeen years old, and the perpetrator of the crime, a young man, who introduced the foreign body after having had intercourse with the girl. A few hours after its introduction it was removed, and then weighed six drachms and a half.

In general the effects produced by these foreign bodies depend upon their form, size, material, the greater or less violence done in their introduction, and the length of time they remain.

They usually produce more or less irritation of the vaginal mucous membrane, with increased secretion. In many cases an obstinate leucorrhœa, compelling the patient to seek professional advice, leads to the discovery of the foreign body. The increased vaginal discharge is at first mucous, then muco-purulent, or purulent, or it may be serous, but after a time becomes more or less offensive in odor—in some cases so offensive as to suggest malignant disease, a suspicion which may be confirmed by the occasional or frequent occurrence of hemorrhages. The foreign body may interfere with the functions of neighboring organs, especially those of the bladder and rectum; hence vesical irritability or dysuria, or rectal tenesmus, in some cases dysentery.

The vaginal surface may be abraded, or ulceration of the walls occur from pressure of the foreign body; adding to these the offensive character of the retained vaginal secretions, we have the conditions which may lead to septic infection. Kottman* has reported a death from this cause in a woman twenty-five years old, who introduced a spool into the vagina, and who had suffered from leucorrhœa several years. The spool was found behind the cervix in the vaginal vault, and removed; symptoms of peritonitis were well marked, and the patient died; the post-mortem showed purulent exudation in the pelvic peritoneum, especially in the recto-uterine cul-de-sac at a point corresponding with that which the spool had occupied in the vagina.

Runnals† has reported a case of death from pyæmic pneumonia and peritonitis, occurring in a girl of twenty-four years, caused by the retention of a piece of sponge in the vagina; the measurements of the sponge, removed after death, were three and a half by two inches.

A girl,‡ eighteen years of age, was admitted into Hotel Dieu, Orleans, apparently in the last stages of marasmus, and complaining of hypogastric pain, and diarrhœa. The next day she died, and upon post-mortem examination, there was found in the vagina a pewter cup, which had been introduced fourteen months before: it is stated that the cup could not be removed before dividing the pubic joint.

Dr. Kelly,* of Philadelphia, was consulted by a woman seventy-five years old, who had worn a pessary fourteen years without inconvenience, until recently difficulty in defecation and urination, together with an offensive vaginal discharge, led her to seek professional help. The doctor, not without considerable difficulty, removed the pessary, but the woman soon manifested a typhoid condition, and died three weeks after the removal.

The presence of a foreign body having been determined by vaginal examination, by touch, mediate or immediate, by sight, where possible, and the vaginal examination assisted, if necessary, by examination through the bladder and the rectum, the plain indication is to remove the foreign body.

Here one cannot refrain from stating the very great advantages the practitioners of to-day have given them by Sims' speculum and anæsthetics in such removal.

An anæsthetic is not necessary in all cases, but is especially in children, and when the foreign body is large.

So far as methods of removal are concerned, these vary with the size and form of the body, and its material, and as to its being free or fixed in the vagina. In many instances the conditions require a new method to be devised.

In some instances the foreign body can be best removed by acting on it through the rectum. Thus Meissner removed a pebble from the vagina of a girl 2½ years old; of course very much less violence was done by the finger in the rectum, than if it had been introduced into the vagina. Small round bodies can be best removed by throwing into the vagina a stream of water, while the perineum is retracted by Sims' speculum. The removal of fragments of glass, especially of a syringe, is often difficult; if forceps be used, there is danger of breaking the glass, or of wounding the vagina; in the only two cases I have had to remove the pieces of a broken glass syringe, this was done by the fingers, and, in general, flat bodies are thus best removed.

One of the most ingenious devices for the removal of fragments of glass was used many years

*Schmidt's Jahrbücher, 1875.

†British Medical Journal, July, 1882.

‡Lancet, vol. i, 1848.

*Medical News, Philadelphia, 1884.

ago by Dr. Levis. A woman had a broken glass pessary in the vagina, and the efforts that had been made to remove the pieces had only resulted in reducing them to smaller pieces, comminuting them in fact; a severe vaginitis—due chiefly to the fragments of glass, but in part, probably, to the attempts at extraction—was present when the patient came under the care of Dr. Levis. He threw into the vagina by means of a syringe a mixture of plaster of Paris, and after two or three days removed the mass, the solidified mixture having fixed in it the various pieces of glass. This unifying process, so ingeniously resorted to by Dr. Levis, seems like a material illustration of Plato's axiom that the end of philosophy is the intuition of unity.

In some cases it has been necessary to reduce the size of the foreign body before extracting it. Thus Dupuytren broke the pomade-pot, and, by means of strong forceps devised for the purpose, divided the ivory pessary in the vagina and in the rectum, removing one part through the latter, the other through the former. In other cases the vaginal orifice has been enlarged by incision, as was done by Gaubius for the removal of the calcified uterine fibroid, and by Sutton for the removal of a globe pessary. If granulations have fixed the foreign body, these must be detached by the finger, or divided by scissors.

If the foreign body have its size greatly increased by mineral incrustations, it is advised to remove these first. Another reason for their removal lies in the fact that in some cases the rough, jagged surface may injure the vagina when extraction is done. Sabatier speaks of his fingers being wounded by the "asperities of saline incrustations," which had made the tumor "as rough as a rasp."

In some cases the ordinary polypus forceps is an excellent instrument for removal of a foreign body, but this removal should then be made by sight rather than touch—a Simon or a Sims speculum being used to expose the vaginal cavity.

In others the foreign body has been so large that the obstetric forceps has proved necessary for its removal. Roux, probably, was the first to use the instrument for this purpose, though some since his day have suggested its utility, imagining they were proposing something new; this is like many other novelties in the medical world which are exhumed from the grave of years, or even of centuries.

Whatever means, manual or instrumental, are used for the removal of foreign bodies from the vagina, it is well to be guided by the words which Blundell said could be usefully inscribed on one of the blades of the obstetric forceps: *Arte, non vi.*

In all cases where there is an offensive vaginal discharge, or any erosion or ulceration of the vaginal walls, antiseptic injections should precede, and for some time follow, the removal of the foreign body.

THE ROLE OF BACTERIA IN PARTURITION.*

BY HENRY O. MARCY, A. M., M. D.,
Of Boston.

Under this title Dr. Marcy read a carefully-prepared paper upon the processes of parturition and the dangers incident to septic exposure.

He premised by a review of the processes of reproduction, embodying the results of his own investigations, undertaken to verify the teachings of the great Italian master, Ercoloni. The uterine glands elaborate the so-called catamenial decidua. Of the same glandular product is the decidua of pregnancy—*D. Vera.* This glandular secretion serves for the nutrition of the fœtus during the early period of pregnancy; later the nutritive fluid is elaborated by the complex glandular organ known to us as placenta. The Serotinal or secretory cells of this organ are themselves elaborated from the sub-mucous layer of uterine connective tissue, and when these are separated, as a more or less perfectly formed placenta, there takes place an extensive traumatic lesion of the uterus, laying bare the uterine tissue of the entire placental site.

Uterine contraction rapidly reduces the extent of this traumatic lesion pari passu with the size of the organ, and this process also hastens the proliferation and expulsion of the broken-down, used-up material.

This must be *physiologically* an aseptic process.

The *pathological* factor must lie in abnormal and extraneous conditions.

The most common and important is the hitherto *x* factor in the problem, now, at least in part, recognized as bacterial ferment. Whence its origin? Certainly from without. If excluded from foreign contact or atmospheric exposure, the uterus in its injuries, even in the cervical portion, may be likened to a subcutaneous wound. Then the lochial secretion remains a non-irritant, innocuous fluid, although a highly albuminous fluid swimming with broken-down cellular debris.

Micro-organisms are usually found in the vagina in health. Would this furnish the seed

* Read before the American Medical Association, April, 1885.—Abstract.

for septic infection? Were this true, why does not every woman have after labor a septicæmia? The belief that herein lies danger is widespread, as evinced by the earnest advocacy of a large number of our most experienced and thoughtful practitioners of the vaginal douche in normal labor.

This belief is greatly strengthened by the common observation, that the napkin used for the absorption of the lochia has a decided unpleasant odor; and if the secretion be examined microscopically it will be found teeming with bacteria-termo, the omnipresent scavenger of nature for taking to pieces and perhaps refitting for higher uses our waste albuminous compounds. It is possible by this very process that this material is diverted from falling into the hands of and feeding an army of most dangerous enemies. This, in the mind of the writer, was the explanation why, amid filthy surroundings, the unwashed, unchanged, uncared-for women so very generally make a good recovery.

Dr. Marcy emphasized cleanliness as important for the same general reasons imperative in wound treatment; but because of the physiological conditions and relations, as above sketched, he discards as unnecessary the vaginal douche in normal labor. He quoted from an exhaustive paper by Dr. Z. B. Adams, of Framingham, Mass., many facts showing that the douche thus used, even in competent hands, might be a source of danger, even death. Prof. Schroeder, of Berlin, has recently had two fatal cases where the mercuric bichl. sol. 1 to 1000 was used.

In all operative cases, however, where septic infection might supervene therefrom, Dr. Marcy would insist upon the most rigorous exercise of antiseptic precautions as the fundamental factor of preventing infection. This had been advocated in the Boston Gynecological Society by the writer six years ago—a surgically-clean operator, clean instruments, etc.

The same general conditions pertain to the problem as belong to operative wounds. It is, however, emphasized and rendered much more important than in ordinary wounds, when the general conditions are thoughtfully considered. In both cases there must exist not only the *seed* as the danger material, but also the *soil*. The planting ground is rarely the vagina, but the uterine cavity. It is difficult to conceive of an incubating chamber presenting more favorable conditions, the albuminous fluid furnishing abundance of food, the heat-point steadily maintained: open sinuses, lacerated vessels, denuded walls, through which ramify an abundant net-work of lymphatic vessels, all furnish conditions for generation and absorption rarely equaled. Micro-organisms thus rapidly generated are distributed with astonishing facility, and a general infection rapidly supervenes.

Dr. Marcy followed with a series of interesting experiments to show that the danger resulted, as a rule, from micrococcal and not bacillary poisoning. This was deemed the more important, since here the odor was not marked, only slightly sour, and therefore that which has usually been considered an important characteristic is wanting. Viewed from this standpoint, the subject of puerperal fever assumes a new and more intense interest. No subject in preventative medicine is of greater importance, and there can be no doubt that lives in large numbers have been saved by the adoption of wise precautionary measures, based upon the knowledge already attained of the role of micro-organisms in puerperal lesions.

Dr. Marcy closed by insisting that the subject, instead of being exhausted, was opening up new fields for better study and richer fruitage. Hecatombs of lives, of women in the ripe maturity of their usefulness, should no longer be annually sacrificed through the ignorant violation of laws now demonstrated.

Hospital Reports.

CLINICAL LECTURE ON CARDIAC DISEASE IN ADOLESCENCE—ACUTE AND CHRONIC PERICARDITIS—HYDRO-PERICARDIUM.

BY JOHN M. KEATING, M. D.,

Visiting Obstetrician to the Philadelphia Hospital and Lecturer on Diseases of Women and Children.

Reported by WILLIAM A. EDWARDS, M. D.,

Assistant Demonstrator of Clinical Medicine, University of Pennsylvania; Medical Registrar Philadelphia Hospital.

Before proceeding directly to the cases before us, it is perhaps as well to brighten up our knowledge of the pericardium and its topographical anatomy.

The heart, the origin of the large vessels, and the serous pericardium, are contained within and enclosed by the fibrous sac of the pericardium. The pericardium is situated in the median line of the thorax between the two lungs and the pleuræ; posteriorly it is in relation with the posterior mediastinum, separated from the spine by the connective tissue inclosing the trachea, descending aorta, great vena azygos, intercostal arteries and veins, thoracic duct, œsophagus, two pneumogastrics, and both sympathetic nerves and lymphatic glands.

Anteriorly, the pericardium is separated from the sternum by connective tissue and the anterior border of the pleuræ.

The sac of the pericardium is shaped like a triangle; the apex of this pericardial sac is fixed to the skeleton by three important ligaments. It is fixed to the vertebral column by the suspensory ligament of the pericardium, sometimes unfortunately called Beraud's* ligament, as by giving men's names to anatomical structures we simply complicate matters. It is inserted into the middle and left lateral portions of the third cervical vertebra.

The second ligament of fixation is the cervico-pericardial pseudo-aponeurosis of Richet; this coalesces with the middle aponeurosis of the neck, and is inserted into the hyoid bone.

The third support has been described under two heads, as the sterno-pericardial and the costo-pericardial ligament.

It is also upon these ligaments that the great vessels going to and arising from the heart are supported. The base of the pericardium is fixed to the centre of the diaphragm. Those of you who desire more extended data on the anatomical points I would refer to the work of Constantin Paul.

The pericardium has two layers, parietal and visceral; the latter is thin and separated from heart-muscle by connective tissue; it is here that you often see excessive quantities of fat deposited. The serous cavity contains a variable amount of fluid, which is alkaline, and made up of water, albumen, fibrin, salts, solid parts, and extractives.

Let us now now examine our case. Willie O., æt. 14, first complained of a sharp, severe præcordial pain below the nipple, and radiating towards the ensiform cartilage; this was its maximum intensity. It was quite painful throughout the entire præcordial region, and even in the epigastric and left hypochondriac regions. He tells us that coughing made it worse, as did also the respiratory act; he describes the pain as lancinating or tearing, and almost unbearable. The causes of this *acute pericarditis* are many. It is seen with endocarditis and rheumatism; after scarlatina, as an extension from the pleura; it may arise as a sequel of acute Bright's disease. A septic form of endocarditis, and also, possibly, of pericarditis, may have its origin in the new-born babe from an umbilical sore. Occasionally it is seen in typhoid fever, variola, and erysipelas.

Steiner makes the observation that the usual rule in practice is to consider all cases of heart disease that occur before the age of four years to be congenital; but Goodhart † takes exception to this statement, as sixteen of his cases occurred under four years of age, and Cox records a case of pericarditis in an infant eleven days old.‡

Acute pericarditis is seen more frequently in children than in adults, in association with infective osteo-myelitis and abscess in the heart.

The *symptoms* of pericarditis may be very obscure; in some cases but few symptoms are presented, the child loses flesh, becomes breathless, palpitation is noted, and a short dry cough would complete the symptoms of one of these obscure cases. When the pericarditis is accompanied by a serous effusion in one of these young emaciated subjects, the enlargement of the pericardium can sometimes be easily detected simply by inspection. Graves has noted in infants the pushing out of position of the left lung, its apex extending into supra-clavicular fossa.

There are certain general diagnostic symptoms that you must learn to note. The temperature is apt to be high, but undergoes decided fluctuations; dyspnœa may be extreme and threatening, the nares dilate, sometimes as markedly as they do in pleural effusions. Hiccough is frequently noted, the face is pale and expression anxious. Your patient may be in a state of delirium or of extreme wakefulness.

If you lay your hand on the præcordia in the early stage of this affection, when the fibrinous exudate is undergoing formation, a rough friction may be felt. It is well when seeking this sign to ask your patient to lean forward. The friction of course disappears as soon as the effusion occurs, as the two surfaces of the inflamed pericardium are then removed one from the other.

Percussion is a most important aid; much more so in children than in adults; a difference in the percussion note may be elicited by changing the position of your patient; this, however, is a difficult feat in physical diagnosis when dealing with young and often ungovernable children.

Auscultation enables you to "clinch" the diagnosis; the pericardial friction sound is absolutely diagnostic; the only thing that you may mistake it for is a pleural friction; this point is easily definitely settled by asking your patient to refrain from breathing; the pericardial murmur will now be seen to be synchronous with the cardiac rhythm, and the supposed friction rale to have disappeared.

You can increase a pericardial murmur by pressure; it is also very superficial, and is not propagated, as you know valvular murmurs are. You will generally find these friction murmurs to have their greatest intensity at the left border of the sternum, in the third or fourth intercostal space. The time of the murmur is systolic; that is, when the two inflamed surfaces rub against each other, it is sometimes heard in diastole when these surfaces leave each other. Some observers time the murmur as just before the first or systolic cardiac sound. The sound is generally rough. Collier compares it to new leather; it has been described as scraping or rasping, rubbing or rustling. Another point worth bearing in mind is that the murmur is greatly acted upon by active therapeutic measures; cups, leeches, or counter-irritants almost wholly alter its character; it is also modified by position, and it is more likely to be rough than soft.

Acute pericarditis may entirely recover, or it may become *chronic*. The condition of affairs that Stokes called pericarditis obliterans and Bouillard ankylosis of the heart, we generally now term one of pericardial adhesions.

These adhesions take various forms; bands are sometimes formed, which may break and result in long filaments attached at one end to the pericardium; at other times partial adhesions may be scattered here and there, or you may see the adhesions general. The adhesions may be firm, tense, and hard, or thin and easily removed; they may be so extensive as to obliterate the sac of the

*Gazette Médicale, 1862, p. 162.

† Diseases of Children, 1885, p. 527.

‡ Bull, N. Y. Path. Soc., 1881, p. 8

pericardium, the visceral and parietal layers being, as it were, glued together.

In later life these adhesions may undergo various degenerations—calcareous, tubercular, or cancerous.

Betrier * observed these extensive adhesions as early as eleven months.

The *symptoms* of pericardial adhesions are more or less obscure, and often overlooked. This lad, aged fifteen and a half, in whom we suspect the presence of this condition, gives us a history of antecedent acute pericarditis; and, indeed, this is a valuable aid in diagnosis; in many cases the question of the existence of adhesions remains hypothetical. Systolic retraction of the intercostal spaces merits a certain amount of attention.

An observer is of the opinion that if cardiac hypertrophy is present, with a violent impulse of the heart as a whole, but a feeble impulse of the apex, we are justified in suspecting pericardial adhesions.

Chronic pericarditis is, as a rule, a sequel of acute, or of rheumatism; it is not very frequent in children.

Hydro-pericardium is an infrequent disease in childhood. It is a concomitant of dropsy, or anasarca; the sub-serous tissue becomes œdematous, and an effusion is poured out into the sac. No trace of inflammation is to be noted upon the pericardium. It is due to a local or general condition; locally stasis in the veins or lymphatics of the heart or surrounding parts could cause it. Other cases may have as their etiology, nephritis generally parenchymatous, dropsy, tuberculosis, or more rarely cancer.

The affection generally sets in as the last act in one of the above grave diseases, and the diagnosis under these circumstances is difficult in the extreme. Such a case would probably present a small, weak pulse, cyanosis, decreased urinary secretion, compression of lungs, and pushing down of the diaphragm, with increased præcordial dullness and muffling of the heart sounds.

Solicitous parents will always desire to know your *prognosis*, and remember that acute peri- and endocarditis are more liable in children than in adults to lead to a rapidly fatal termination. In children rapid dilatation of the cardiac cavities may suddenly occur, and the child succumb to cardiac arrest. Remember also the younger the child the more rapidly will emaciation occur, hence your prognosis should be guarded, more especially should you discover consolidation of the lungs, great rapidity, or turbulent heart action. Vomiting would be a prognostic sign of evil omen; inability to lie down or take food, together with insomnia, should put you on your guard.

In the *treatment* of acute pericarditis, the first indication is the relief of pain. Opium is borne well in cases of children between the ages of six and fourteen. Absolute rest in the least distressing position, the head not very high, the senses not disturbed, no light, noise, or conversation, are all essentials in the treatment. This absolute rest is the more important, as the heart may have deposited on it a large layer of lymph, its muscles degenerating and its cavities dilating.

You should restrict the patient to a liquid diet, such a diet as will place the least possible strain upon the heart.

Counter-irritation by a blister is perhaps the best method of treatment. The blister should be large and allowed to draw well.

Dr. Beale suggests the following application after the blister has risen:

℞.	Pulv. opii,	℥j.
	Ungt. hydrarg.,	℥j.
M.	Ft. ungt.	

An ice-bag may be applied in cases of high temperature with tumultuous heart action and frequent pulse. You must watch its action so as not to depress the patient. Belladonna, bromide, and iodide of potassium may be given to fulfill their well-known indications.

A child of say ten years may take three to four ounces of wine per day as indicated. The great frequency of the pulse and the condition of the nerves of the heart can be met with digitalis.

℞.	Tr. digitalis,		♏xx–xl.
	Pot. bromid.,		gr. xl.
	Mucil. acaciæ,		
	Syrupi aurant.,	āā	f. ʒiij.
	Aquæ, q. s., ad.,		f. ʒiv.

M. S.—Tablespoonful three times a day for child 6 to 12 years of age.

Of course, should rheumatism be at the root of the trouble, you must actively treat it. Sodium salicylate could be given cautiously and in small doses, watching its action intelligently.

Day suggests the following in rheumatism:

℞.	Pot. bicarb.,	ʒij.
	Pot. nitrat.,	gr. xv.
	Tr. opii,	♏xvj.
	Syr. limoinis,	f. ℥ss.
	Aquæ, q. s. ad.,	f. ʒiv.

M. Dessertspoonful every three hours for a child six years old.

The treatment of serous pericarditis, or pericardial effusion, brings up the question of paracentisis pericardii; serous effusions in children possibly have a tendency to form pus more readily than in adults, so bear this in mind in a prolonged case of pericardial effusion, more particularly should your patient be sick, pale, and anæmic. In a case like this, I should consider it good practice to explore the pericardial sac by a fine hypodermic needle; if pus should be found, you, of course, must establish free drainage. I would impress upon you the great importance of keeping a hypodermic syringe and needle solely for exploratory puncture, as in many cases it is almost impossible to settle the question of the presence or absence of fluid without this puncture.

Diuretics and hydragogue cathartics have been tried in cases of pericardial effusions without, I think, doing very much good. The most usual ones of the former class are squills, nitrate and acetate of potash, and of the latter, jalap, scammony, colocynth, and elaterium.

The treatment of pericardial adhesions consists in the application of blisters and the administration of saline aperients, iodide of potash, and anti-rheumatic remedies.

During convalescence, see to it that your patient has absolute rest and avoids all bodily exer-

* Constantin Paul, Diseases of Heart.

tion; a child should not be allowed to place its feet on the ground at all, but the nurse should be directed to carry the little patient. You must frequently note the pulse rate and heart's action, order an easily-assimilated diet, direct the proper hours of rest and sleep so that the heart may rest as the body does during sleep. Iron is now indicated to restore nutrition of heart and enable it to repair any damages.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Gestation in a Sarcomatous Uterus Simulating Extra-Uterine Pregnancy.

By Dr. Bernardy.

October 3, 1884, I was requested to visit Mrs. McG., delicate, aged about thirty, married six months. She was said to be suffering from a cold. I found the patient up. Temperature 105°, pulse 130, with a high fever and a severe cough. Examination of the lungs revealed double pneumonia. At the same time noticing the abdomen prominent, I inquired and was informed that pregnancy was five months advanced. The abdomen was rather large for that period. On Sunday, October 5, she complained of a sharp pain in the right inguinal region, the pain was excruciating and demanded the administration of large doses of morphia before any relief was obtained. I found the right inguinal region filled by an immense growth reaching almost to the lower border of the liver. The uterus, or what appeared to be the uterus, was enlarged and pushed well toward the left side. On vaginal examination, found the right side of the pelvis filled by a growth. At first thought I detected fluctuation, but closer examination showed it to be hard to the touch. The uterus was jammed well toward the left, and was immovable, the neck somewhat absorbed, the os tilted up behind the pubis. To reach it, the finger had to be passed well upward; it was closed and soft. The patient had never had any uterine trouble, menses always came without pain; they never appeared after her marriage, which occurred one week after a period. Her health remained good for three months after marriage, when, while out walking, she was suddenly seized with a sharp, lancinating pain in the right side of the abdomen. The pain was so great that she almost fainted, but being a woman of strong will, she finally, after suffering terrible agony, reached home, and went to bed. No physician was called in; next day there were slight traces of blood on her night-dress. Under absolute rest, the pain subsided, and at the end of a week she was about her household duties. The pain in the side returned if she over-exerted herself. Sexual intercourse was painful, and was followed by traces of blood the next day. Believing that the symptoms pointed to either extra-uterine pregnancy or a tumor complicating pregnancy, I asked Dr. Goodell to meet me. By the time the consultation was held (October 8), a severe attack of peritonitis had commenced. This complicated matters, as a close examination was impossible. On account of the distended and painful condition of the abdomen it was impossible to trace any outline of the growth or uterus. It was decided that the symptoms and history pointed to extra-uterine pregnancy, but that undoubtedly the uterus contained something, whether tumor or child, in the present condition of the patient, it was impossible to decide; the leaning was toward a pregnant uterus. By October 16 the peritonitis was under control; the lungs no better.

October 19 I was sent for, the messenger stating that there was a renewal of the peritonitis. I found the patient in active labor, the fœtus descending rapidly. In half an hour labor was completed. I readily detected the large growth filling the upper portion of the right side of the pelvis. The uterus was surrounded by a hard growth. The cervix was hard. From this time the lungs improved, but she remained extremely weak, and there was a constant dribbling of blood from the vagina.

November 3, the growth was still present, and the cervix hard, and I began to think of malignant disease in connection with the tumor. I had applied, night and morning, to the abdomen, ungt. hydg., bellad. and iodine, equal parts. This seemingly had the effect of causing the absorption of the large growth, but the mass surrounding the uterus remained the same.

November 27, vomiting occurred, and was arrested with difficulty. A bloody discharge from the vagina and a constant sore feeling over the region of the uterus, which was still towards the left side. The patient's condition was good; she was extremely weak; the slightest exertion would exhaust her and bring on bleeding from the uterus.

December 26, I found her suffering from pleurisy, the left pleural cavity full of fluid.

January 1, abdominal dropsy had set in. A consultation with Dr. Goodell was held. A positive diagnosis of malignant disease was made.

Prognosis,—Death at any moment. She died suddenly the same evening, while talking to her husband.

Post mortem examination by Dr. E. A. Russell twenty-four hours after death. Patient greatly emaciated.

Thorax.—A large amount of effusion completely filling up the left pleural cavity, while the cavity of the right side was partially filled; both lungs were compressed upwards, no adhesions. On section the lungs appeared mottled, and were hepatized in general appearance, but were otherwise healthy.

Heart.—On opening the pericardium, found a moderate amount of serous fluid vegetations on mitral valve, weight 11 ounces.

Abdomen.—Entire cavity was greatly distended with a dark fluid, full of broken down lymph. The intestines were forced upwards. There were slight evidences of beginning peritonitis. A portion of the ileum on the right side presented a black, unhealthy appearance, bordering on gangrene. The uterus was increased in size. The outer surface presented an irregular, mottled appearance; large veins covered its surface; at the fundus there appeared a spot about one inch in diameter, of a bluish tinge. On pressure by the finger, the surface readily broke. Underneath

was a cavity about the size of a large hickory-nut. It did not communicate with the interior of the uterus. On opening the uterus its cavity was found to be almost obliterated; the tumor seemed to have entirely absorbed the true uterine tissue with exception of the neck. In the body of the tumor were observed small masses or growths varying in size up to that of an egg. The ovaries were small and seemed to have participated in the general disease. Microscopic examination proved the tumor to be of the adeno-sarcoma variety.

At first I was convinced that I had a case of extra-uterine pregnancy; but the peculiar hardness of the tumor made me doubtful. Here was a patient that had never had any uterine ailment. Marries, becomes pregnant; at the end of the third month, without any premonition, while quietly walking, is seized with pain of an excruciating nature in the right side, goes to bed and remains quiet; the next day blood flows from the vagina. She remains comparatively well for two and a half months more, when she is again suddenly seized with pain in the same side, followed by peritonitis. A tumor is found in the affected side, the uterus is enlarged, but not sufficiently so for a five and a half months' pregnancy, the os giving no signs of that softening which should accompany pregnancy. Could we have a group of symptoms more allied to those of extra-uterine pregnancy?

Dr. J. M. Keating made some remarks on

Infant Feeding.

He said: At my request Dr. Charles Potts has instituted a series of experiments which have a decided practical value, and we hope to present them to this society at an early date in full. I desire to place on record a statement of the results so far reached which appear to be interesting and important. The question often arises, Is it of advantage or not for an infant to be partly nursed and partly bottle-fed? What action has milk upon starch, if any? To answer this the following tests were made: (1) Sample of milk composed of the milk of several women—a quantitative estimation of the sugar in it by Fehling's method showed 6.84 per cent. 10 cc. of this milk was then taken and ½ grain of powdered starch added, allowed to stand at a temperature of 99° for thirty minutes, after which 5 cc. diluted with 45 cc. of distilled water was tested, and showed 8.62 per cent. of sugar. The other 5 cc., after standing sixty minutes, gave 9.09 per cent. (2) Another sample found to contain 7.14 per cent. of sugar had a ½ grain of powdered starch, as in No. 1. In thirty minutes it gave 9.803 per cent. of sugar in 5 cc. The other 5 cc., after remaining sixty minutes, gave 8.62 per cent. Possibly part of the sugar deposited and was drawn off with the first 5 cc. (3) Another sample showed 6.32 per cent. of sugar, and after adding the starch as before, gave in the first 5 cc. 8.19 per cent. The next 5 cc. 7.93 per cent. These investigations showing that the women's milk gave an increase of sugar after digesting with starch.

Experiment (4) A sample of cow's milk was tested and found to contain 3.87 per cent. of sugar, to this was added a ½ grain of starch to 10 cc. At the end of thirty minutes 5 cc. diluted with 45 cc. of distilled water, showed no increase of sugar. (5) A sample of cow's milk gave 4 per cent. of sugar, and was treated as before, but at the end of thirty minutes, and then sixty minutes, it gave the same result. (6) Another sample of cow's milk gave 3.703 per cent. of sugar, was treated as before with same amount of starch. In thirty minutes 5 cc. gave same result; in sixty minutes 5 cc. gave same result. These investigations showing that cow's milk gave no increase of sugar after adding starch. Does the acidity of cow's milk prevent the sugar change? Does the sugar change continue in an acid medicine? (7) Took another sample of human milk from one woman. It yielded 6 25 per cent. of sugar; added starch as before. In thirty minutes 5 cc. gave 7.14, and in sixty minutes 5 cc. gave 7.6 per cent. Took 10 cc. of this milk (6.25 per cent. sugar) and added a few drops of C. P. dilute hydrochloric acid, enough to faintly acidulate it, and then added ½ grain of starch and let it stand as before. In thirty minutes 5 cc. gave 6.41 per cent., and in sixty minutes 5 cc. gave 7.35 per cent. of sugar. (8) Another sample of woman's milk without starch gave 6.17 per cent., with starch 7.24 per cent.; 10 cc. of the same, acidulated with hydrochloric acid, C. P., diluted, gave in thirty minutes 7.35 per cent. In these tests 10 cc. of Febling's solution were used with 40 cc. of distilled water.

If future investigations prove the correctness of these statements, we may safely assert that the nursing woman may supplement her breast milk with some well-prepared digestible form of food containing a small quantity of starch advantageously, and also that the amylolytic ferment will remain active in the slightly acid stomach of the infant. W. H. H. Githens, Secretary.

CHICAGO MEDICAL SOCIETY.

Stated meeting, June 15, 1885. The President, C. T. Parkes, M. D., in the chair.

A Successful Case of Nephrectomy.

Dr. R. G. Bogue reported an important case of nephrectomy. The patient was a woman, aged thirty-six, single, who had suffered from several attacks of acute rheumatism with cardiac complications and also for nearly one year with a pus-discharging sore on one arm. About six years ago, while doing laundry work, she severely strained her back, and this was followed by frequent and painful urination, the urine containing pus, blood and and mucus. The pain in the back increased during menstruation. These symptoms continued until 1882, when a swelling, accompanied by pain and soreness, appeared in the right lumbar region. This swelling was finally opened and gave exit to a large quantity of pus, and remaining open, continued to discharge pus until the time of the operation, pus, blood, and mucus at the same time appearing in the urine, which was voided with difficulty. At one time there was so much clotted blood in the bladder it was only dislodged by breaking up the clot with a catheter and washing out the bladder. Later, there was nearly a closure of the opening into the lumbar abscess, and a fluctuating tumor appeared near the old one, which was opened and gave exit to a quantity of fœtid pus. From May 13 to Au-

gust 27, 1884, there was a free discharge of pus through the lumbar openings and the bladder. At no time was there a urinous odor to the discharge from the loin. Whenever the discharge from the loin was greater, pus appeared in less quantity in the urine, and vice versa.

Believing that there was an abscess of the right kidney, on August 27, 1884, Dr. Boyne made an exploratory operation by making an opening into the loin along the course of and just below the twelfth rib, including in its track the sinus. He came upon a dark, fluctuating mass, which upon puncture, discharged a quantity of pus, and on further examination, was found to be the capsule of the kidney, divided into compartments and distended with pus. The sac was adherent to the surrounding tissues, and upon separation, bled freely. The adhesions were quickly broken up and a stout ligature placed around the attachment or peduncle, which was the ureter and renal blood-vessels. This was done by the aid of a large bent probe armed with silk. This ligature completely arrested the hemorrhage. Near this ligature the peduncle was transfixed by a double thread of strong silk and tied in two parts, the mass cut away, with ligatures left long, and with drainage-tube, served to drain the cavity, which was cleansed with a carbolated solution and the wound dressed with oiled silk, gauze, and oakum. The patient convalesced rapidly with the exception of an attack of rheumatism and one rather free discharge of blood from the bladder, which followed traction on the ligatures. The ligatures did not separate until December 7. But little pus came with the urine after the operation. There is yet a small fistulous opening in the track of the wound. The patient is now comparatively well. The mass removed was a distended kidney capsule, with calices so distended that there was obliteration of the kidney tissue, except at one point where there was enough to identify the structure.

Dr. C. T. Parkes remarked that an interesting point in the report is where it is described how hemorrhage was arrested, as the greatest danger in this operation is from hemorrhage. Czernay had a case in which the hemorrhage was so severe that he ligated the aorta. Operations on the kidney are becoming quite frequent. In an interesting paper Dr. Gross gives his observations of over 200 cases, and limits the cases in which an operation is suitable. Dr. Parkes said that he wished to call the attention of the society to the fact that there is sometimes an anomalous distribution of the arteries to the kidneys. He had met two cases in which the arteries entered the kidney at the lower end instead of the hilus, and this should be remembered in cases of nephrectomy, and especially nephrolithotomy. Sometimes the renal artery enters the kidney by two branches,

In answer to several questions by members of the society, Dr. Bogue replied that no vertical incision was necessary, that the diagnosis was positive only after the operation, which was an exploratory one, that the ureter and renal blood-vessels were ligated in mass, that in a supposed case, when there was a well defined, movable tumor in the abdomen, unaccompanied by pain, pus in the urine, with difficult urination, which was relieved by washing out the bladder. If there was a reasonable probability it was a suppurating kidney, he would advise an operation.

The Continuous Curve Forceps.

Dr. E. W. Sawyer read an interesting and exhaustive paper on the continued pelvic curve in the obstetric forceps, with remarks on forceps in general. He defined the perfect obstetrical forceps to be an instrument with which it is practically impossibile to injure the mother or fœtus when skilfully used. In order that the forceps may be such an harmless extractor, after many years of observation and experience, he had arrived at the following conclusions: First, that there should be a space of three and one-fourth inches between compressing surfaces of the blades, when the inner surfaces of the handles are in contact. Any less space will fatally compress the fœtal head. The long diameter of the ellipse bounded by the conjoined grasping curves of the blades should be five and one-half inches, the distal opening of this ellipse, corresponding to the separation between the tips of the blades, may be three-fourths of an inch; five and one-half inches from the blade tips the opening should be two and one-half inches. If these measurements are less, severe injury may result to the fœtus. Second, in selecting an instrument a straight-edged ruler should be placed at right angles to the long diameter of blade, to determine if the outer edge of the blade and the border of the fenestra are on the same plane; if not, such an instrument invariably injures the fœtal scalp. Third, the loose mortise joint lock, allowing a backward and forward motion of the handles, and thus enabling the obstetrician to properly adjust the forceps to the fœtal head, is the only safe, simple, and easily operated lock. Fourth, in compressing the fœtal head the closest imitation of nature is safest to follow, hence a moment of compression during a pain should be followed by loosening the grasp of the head, which cannot be done with those instruments which admit of the handles being fixed together. Fifth, the length of handles should be such as to allow the operator to reserve his forces for difficult traction. The rounded space just in front of the lock, admitting of the introduction of a finger, is of special value as a point of traction when a great degree of compression is not demanded. Sixth, the blades of the instrument should be of the best steel, at least one-fourth of an inch square at the shanks, and gradually thinned to about three thirty-seconds of an inch at the tips. Slighter material is so yielding as to permit the blades to be pulled off the head. Seventh, if an index be fixed to the fœtal head, as for example the handles of a forceps, in such a manner as to follow the direction given to the head by the unaided efforts of nature, an irregularly curved line would be described forward and upward, which would have its termination, at the moment of the escape of the head, at a point near the umbilicus of the woman. This curved line should be the guiding line to the attendant who attempts to reinforce the expulsive force of the uterus with the forceps. Dr. Sawyer then exhibited a forceps of his own invention, in which the pelvic curve is extended to the ends of the handles,

to guide the operator in producing traction in the direction of the curved line above mentioned. He claimed that in those cases where the occiput, or sinciput, presents posterior, and it is decided to deliver in this position, this curve will allow the operator to grasp the head with the forceps well forward over the ears, without its slipping over the occipital poles.

In answer to several objections as to the feasibility of securing a perfect forceps, Dr. Sawyer stated that he did not claim his forceps to be perfect, but that he had copied the best features of other forceps, and thinks that he has an instrument which will do less injury to the mother or child than any forceps with which he is acquainted. He believes it to be absolutely safe for the child, and was not intending to speak of the indications for using the forceps, or the manner of their use, but endeavored to incorporate in his paper some points about forceps in general which he had never read or heard taught, and hoped they would be useful to all who wished to approximate as nearly as possible the ideal forceps.

Editorial Department.

Periscope.

Hysteria.

Dr. Samuel Bell thus writes in the *Med. Age:*

Perhaps there is no disease which comes within the range of a physician's observation that taxes his resources, medical, moral, and social, any more than an obstinate case of hysteria. The premonitory symptoms in some cases will drive the ordinary diagnostician to his wits' end in order to satisfy anxious friends. Hysteria occurs most frequently in females between the ages of 15 and 24; exceptional cases occur later in life. Young girls, old maids, widows, and childless married women, are the most frequent subjects of the complaint. Charcot attributes great importance to ovarian hyperæsthesia as a cause of hysteria. The general system may be deranged by many conditions, but the sexual functions assume an undue prominence in the mind; consequently, any disturbance in connection with these functions produces an exaggerated effect. Hysteria is rarely found in the male. A semi-hysterical condition is found sometimes between the ages of 35 and 50 years. Among its causes may be mentioned excessive venery, masturbation, overwork, with long-continued anxiety, excessive and prolonged mental labor, and senile degeneration.

Prof. W. H. Thompson, of New York, recently related, during one of his excellent lectures on the above subject, his experience in connection with a case which is, perhaps, not altogether unique. The patient was a female of 20 years. After a careful examination a diagnosis of hysteria was made and appropriate treatment prescribed, with no apparent improvement of symptoms. The case was becoming monotonous to physician and friends. A noted metropolitan neurologist was called in consultation, and acquiesced in the diagnosis which had been made, also saying with emphasis, that any doctor with average knowledge would know that it was a case of hysteria. Ere the consultation closed, they were summoned to the bedside of their patient, only to see her expire.

I have had under my care during the past two months, a young lady 18 years old, stout and robust, well developed physically, and a person of average mental calibre. No history of any abnormal psychical manifestations previous to the present sickness. At my first visit I found her in a hystero-maniacal state, clonic spasms of the muscles of the cervical region, opisthotonos, strabismus, pupils dilated but would respond to light, general hyperæsthesia, with intervals of dysæsthesia; hearing very acute. A whisper would be heard by her in the remotest part of the adjoining room. Continuous vociferation, and persistent efforts to leave her bed and room, made it necessary to use force in order to keep her in bed. Pulse 100, temperature 2° above normal. Pulse full and compressible during the interval of spasm. Her exclamations frequently referred to her head. This symptom is considered by many pathognomonic of hysteria—clavus hystericus. It is described by some as if a nail were driven into the head.

Valerian, bromide of potassium, and chloral, were given, but hysterical vomiting began at once, and for a time the above remedies had to be abandoned. Large doses of morphiæ sulph. were given with some better results, but the raging delirium still continued, and one week elapsed before she recognized her condition, and then only for a few minutes. In three weeks she was able to sit up and walk around in the room, but a few days later all the former symptoms came back in an exaggerated form. After about twelve hours of raging delirium, she passed into a cataleptic condition, and remained so for a long time, all the vital powers seemingly in a state of suspension, except the heart and lungs; were it not for the action of the heart, which was performing its functions, the prognosis must of necessity have been grave.

The pain in the cranial region was a constant symptom throughout her illness. Cantharidal collodion blisters were applied to occipital and temporal regions and top of head, with some improvement in the pain. But change of surroundings and stern moral treatment seemed to exercise a marked beneficial influence upon the patient. The action of the heart becoming very feeble, with absence of the first sound, and palpitation, rendered the convalescence rather tedious.

To enumerate all the symptoms present would require too much space in your columns. Psychical, motor, sensory and sympathetic symptoms were all present, and very obstinate to control.

A snap diagnosis between epilepsy, multiple sclerosis of brain and spinal cord, hypochondria, neuralgia and uræmic coma cannot at once be made, on account of the variety of symptoms manifested. Especially is the diagnosis obscured when no history can be gleaned from patient or friends with reference to abnormal menstruation, which was no doubt the exciting cause. At times enough anodyne would be retained to produce somnia, but tonic and clonic spasms would continue during sleep with less severity, and would be greatly aggravated on waking.

A Case of Mole Pregnancy, Hydatid Mole, or more Properly Speaking, Cystic Degeneration of the Chorion.

Dr. Alexander Davidson reports this case in the *Canadian Practitioner:*

Mrs. W., æt. 45, of dark complexion, has borne several healthy children, last pregnancy was five years ago, when she was delivered of a healthy child; since then she has menstruated regularly until about the middle of January, 1885.

This lady consulted me on the 13th of March, 1885, complaining of being "completely out of sorts," had a constant feeling of nausea, her breasts were enlarged and painful, the areola around the nipple was quite dark in color, with raised papillæ on its surface, the veins over the breasts were very distinctly marked, she had not menstruated since 18th of January last and her tastes and disposition were quite changed; to use her own expression she said, "If it were not for my age I would consider myself pregnant again." Having assured her that although it was somewhat rare for pregnancy to occur at her time of life, yet her age was not an absolute barrier to the occurrence of conception, and her symptoms pointing so markedly to the existence of pregnancy, I deemed that to be her condition. I advised her to go home and wait the course of events, as there then existed no symptoms which should make me apprehensive of her case. Upon this advice she acted, again returning to my office on the 18th of March, when she informed me that since our last interview she had "turned unwell," and that she also observed a "lump" in the lower part of her abdomen, and suffered no pain. I then made a physical examination of the uterus, which revealed the following condition: The abdominal walls were thin and flaccid, just above and behind the pubes in the mesial line was a pear-shaped tumor to be felt; bi-manual examination now confirmed this tumor to be the uterus enlarged to about the size the organ assumes at the third month of pregnancy, the cervix was soft and thick, it was also fissured, the os uteri was patulous enough to allow the introduction of my index finger to nearly the whole length of the cervical canal; I could find nothing presenting. I may here mention that upon bi-manual examination the enlarged uterus seemed to have more of a soft feeling like a bag of bran than the firm resisting feeling of a truly pregnant uterus.

I now saw my patient from day to day until April the 11th, when the hydatid was expelled. The flooding continued at intervals, sometimes in small quantity, sometimes in considerable quantity, and sometimes absent altogether for as long a period as twenty-four hours; the hemorrhagic discharge was not the thick red of normal blood, but seemed to consist more of the watery element of the blood, as if the liquor sanguinis had been expressed from the blood clotting in the interior of the uterus. No portions of the hydatid escaped with the hemorrhage, as sometimes happens in these cases, thus rendering the diagnosis easy.

The enlargement of the uterus was very rapid, reaching at the time of the expulsion of the hydatid as high up as an inch above the umbilicus, and measuring two inches in its transverse measurement. During the progress of the case I observed that the uterus was not steady in its enlargement, some days being somewhat reduced in size, and the next being again enlarged; this temporary reduction in size corresponded to the times when the flooding was most severe.

The pain at no time amounted to anything except at the termination of the case, when uterine action set in to expel the contents of the uterus.

The nausea was at times very severe. My reason for not exploring and emptying the uterus at an earlier period, was the fact that at no time did the life of the mother appear to be in jeopardy.

The point at issue here was the diagnosis. From my experience of this case, I would esteem the very rapid enlargement of the uterus, its soft and somewhat pulpy feel, and the character of the discharge, as very valuable signs in aiding me to a correct diagnosis of a similar case.

The Treatment of Cholera.

The *College and Clinical Record* says:

Professor Da Costa, in a lecture on this subject at the Jefferson Medical College, expressed the following views:

Prophylaxis.—Since filth of all kinds leads to a rapid production of the germs, the locality should be rid of the same. The dejecta and cesspools should be disinfected. Inspect the source of water supply, since the germs can obtain easy access to wells. Drink only filtered water. Speedy burial of the dead should be urged. No change in diet is necessary. Live as usual. Better avoid stimulus in the prophylactic treatment. Among the disinfectants to be used are corrosive sublimate, zinc chloride, cupric sulphate, iron sulphate, and permanganate of potassium.

Internal Treatment.—Must check the early diarrhœa if you desire to be successful, for, in most cases, if you stop this you put an end to the disease. For this purpose the most valuable are sulphuric acid in combination with tr. opii deod., with aq. menth. pip. In India the acetate of lead, grs. iv., with pulv. opii, gr. j., at once with the diarrhœal outbreak, and continue every three hours until it checks the discharges. If the above cannot check the diarrhœa, use capsicum, gr. j., with opium and camphor.

Second Stage.—Here we have cramps, vomiting, and purging. Now, stop the use of fluids; allow but little ice in the mouth. This is a point of great importance. As little food as possible. Stimulus in small amounts, but frequently repeated. Mustard to the epigastrium. Administer, every hour or two—

℞. Tinct. capsici, gtt. ij.
Tinct. opii deod., gtt. x.
Aquæ camphoræ, f. ℥ij. M.

If stomach does not retain the opium, give it hypodermically; but, if possible, give it by mouth, since it appears to have a local effect. To relieve the cramps, use chloral subcutaneously, in large amounts. When reaction has set in, allow fluids to wash out the kidneys. If he has not reacted, and is not doing well under opiates, try calomel, especially in cases in which the secretions have not been arrested by opium. Give at first gr. v. to gr. x., then order gr. ½ every hour or so. When the pulse is sluggish, the temperature below normal, use friction and a hot bath. In this, the stage of collapse, stimulus will not be absorbed or it would be of utility, though brandy or whisky might be tried hypodermatically.

Caffeine, gr. iss.–gr. ij., hypod., stimulates the heart's action. If still the patient fails and the veins are swollen, etc., resort to blood-letting, but possibly the injection of fluids into the veins is better: often the results are marvelous. The thickened blood is made to circulate. Use for this purpose the following:

℞. Sodii chlor., ℥j.
Sodii carb., ℥iij.
Aquæ, Ovj. M.

Get it up to 108° Fahrenheit and a specific gravity of 1.005.

Sig.—Throw in a few ounces at a time, until forty ounces have been injected. When the patient again flags, throw in a like amount.

The inhalation of oxygen has done no good.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The treatment of hay fever is discussed in a reprint by Dr. J. A. Stuckey, of Lexington, Ky. He relies on the local use of chromic acid and cocaine.

——The management of the abscesses in hip disease is explained in a paper of Dr. A. B. Judson's. His recommendations in general are as follows:

1. The increased vascularity attending inflammation in the tissues of the joint requires arrest of motion in the joint, or fixation.

2. The softening of the bony tissue and its increased fragility require that the joint be relieved from the weight of the body in standing, and the direct concussion transmitted up through the long bones of the limb from the heel in walking and running.

3. As the cure is to come by natural processes, it is important that the general condition be kept at the highest possible point of excellence. The patient should, therefore, be active out of doors, and enabled to follow the ordinary pursuits of his time of life.

From the same writer we have received a useful article on "The Mechanical Treatment of Talipes Calcaneus."

——An article on fungous endometritis, by Dr. James B. Hunter, of New York, contains an instructive synopsis of the pathology, diagnosis, and treatment of this troublesome disease.

BOOK NOTICES.

A Treatise on Asiatic Cholera. Edited by Edmund Charles Wendt. Illustrated. New York, Wm. Wood & Co.

This is a combination volume, prepared by Drs. John C. Peters, Ely McClellan, John B. Hamilton, and Geo. M. Sternberg, with the editorial services of Dr. Wendt. It presents a history of the disease; a discussion of its etiology; its symptomatology, course, and sequence; its morbid anatomy, diagnosis, prevention, and treatment. It is a useful digest of the subject. The volume is one of the series of "Wood's Library of Standard Medical Authors."

Medical Thoughts of Shakespeare. By B. Rush Field, M. D., Member of the Shakespeare Society of New York. Published by Andrews & Clifton, Easton, Pa. Pp. 86. Price 75 cents and $1.

Dr. Fields' essay is a creditable study of the great bard from his medical side. All the allusions in his writings which bear upon anatomy, physiology, medicine, or the kindred sciences, are carefully culled from his pages and discussed. Both to the physician and the Shakespearean student, the essay is interesting.

The Ten Laws of Health: or, How Diseases are Produced and Prevented, and Family Guide to Protection Against Epidemic Diseases and Other Dangerous Infections. By J. R. Black, M. D. Cloth, 8vo., pp. 413. Price, $2.00. Philadelphia, J. B. Lippincott & Co.

In the publication of this work the author has contributed an aid of no little value to the sanitary improvement of our country. Addressed to the intelligent public, it is written in a clear and attractive style, and sets forth in an impressive manner the importance of health and the means of preserving it. These include both the positive admonitions of pure air, proper food, and the like, and the negative warnings of what to avoid, what to prevent, and what precautions should be observed in infectious diseases, and unwholesome seasons and climates. The general distribution of such a work cannot fail to increase the happiness of a community, by teaching them those principles of action most conducive to health and activity. The author has conferred a benefit on the public by putting these principles in such an accessible form.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE INFLUENCE OF HIGH ALTITUDES UPON PULMONARY CONSUMPTION.

Dr. Austin Flint, so says Dr. J. M. Snow, in the *N. Y. Med. Jour.*, June 13, 1885, states that he has seen but seventy-five cases of phthisis in which an arrest of the disease took place, and in most of these the improvement was for a short time. When we realize that one-seventh of all deaths are yearly attributed to this cause in the United States, and in Maine fifty per cent. of all deaths between twenty and forty years are from consumption, it behooves us, knowing this failure of the materia medica to cope with the disease, to give our attention to the modifying influence of climate upon chronic pulmonary disorders.

That climate is a potent agent in the prevention of phthisis is demonstrated by the fact that a region of comparative immunity from this disease is found in high altitudes. Consumption is very rare among the native population of New Mexico; and it is stated by Dr. Archibald Smith to be an exotic in the Peruvian Andes at an elevation of 6,500 feet. Küchenmeister and Lombard have estimated the altitude of approximate immunity in Switzerland at 4,000 feet, and at the equator at 9,000 feet. We may see the influence of altitude in our own country: that while the mortality in New York City is 20 per cent., at an elevation of 2,000 feet it is only 10 per cent.

Dr. Denison, of Denver, has placed the altitude of comparative immunity at 6,000 feet; the vital statistics of Denver in four years and a half show but fourteen deaths from phthisis originating in the state.

Damp, ill-drained land, cold, humid air, sudden changes of temperature, lack of sunlight, anti-hygienic surroundings, all contribute to depress the general health, and to occasion the fearful prevelance of phthisis in low-lying districts and in large cities. When in search of a climate for the prevention or cure of consumption, dryness of air and soil, and the invigorating influences of sunlight, must be among the deciding factors.

When we learn that the difference between the annual precipitation of rain and melted snow at Denver, 5,300 feet above the sea, is 14.77 inches

as compared with New York, where it is 42.70 inches, we can appreciate one of the causes of large cities presenting such large phthisical mortalities. Constant humidity of earth and air predisposes most strongly to the development of phthisis; dryness of soil and atmosphere gives to the inhabitants of high plateaux comparative exemption from disorders of the respiratory tract. Laennec mentions a locality where the dampness of the soil was of such a character that two-thirds of the resident population died of phthisis.

The effect of light is to stimulate respiration, and to the consumptive, whose hope of life depends upon the amount of sunlight and out-door exercise he can obtain, the value of a climate like, say, Colorado, may be appreciated when we contrast its 320 sunny days annually with Boston, where one-third of the year is cloudy.

The atmosphere becomes cooler in proportion to the elevation above the sea, 1° lower for every 200 feet; physiologically heat is opposed to stimulation of the nervous centers, its influence upon respiration is also depressing.

Dr. Parkes shows that the number of respirations in the tropics is about 13 to the minute, in England it is 16½. The value of a cool climate in arresting incipient phthisis is well known.

Notes and Comments

Treatment of Gastric Affections.

That muriatic acid has a beneficial effect in many cases where gastric digestion is disturbed is a fact generally appreciated. Dr. S. Talma (*Ztsch. f. klin. Med.*, viii., p. 407,) has recently investigated the action of this acid in cases of dyspepsia depending upon abnormal fermentation. He recommends to administer the acid only so much diluted as it is met with in the normal gastric juice, viz., 1 part to 750 of water, and to use at least sixteen minims of it (the undiluted acid) during twenty-four hours. T., however, mentions that there are some cases where apparently an abnormal decomposition of the contents of the stomach exists; the patients—generally nervous women—complain of acidity and gastralgia, sometimes of a severe character, after meals. In these cases the muriatic acid is not only without effect, but it even does harm, while an alkaline treatment at once improves the morbid symptoms. The mucous membrane of the stomach seems to be very sensitive to the influence of muriatic acid. Whenever dyspepsia appears in connection with cerebral anæmia, or when the former seems to be the direct consequence of the latter, nitro-glycerin has been found by Talma to have a very beneficial effect. He administered this powerful drug three times daily—immediately after the main meals—in the dose of one-third of a milligram = $\frac{1}{130}$ grain each.

We cannot see how a treatment can be successful which is not directed against the main causing element. When cerebral anæmia is present, the dyspepsia is directly produced by it, and nitro-glycerin, at best, can only have a palliative effect by inducing a transient increase of flow of arterial blood to the brain. The object of the treatment in such cases should be the removal of the cerebral anæmia; if this can be achieved, the gastric symptoms will cease by themselves.

Septic Poisoning Caused by the Watery Discharge from the Bowels of a Dead Subject.

Too great emphasis cannot be placed upon the importance of having the hands perfectly free from abrasions of the skin, or sores of any description whatever, by persons who have the handling of dead bodies, whether it be in holding post-mortems, or simply dressing the dead preparatory to burial.

To illustrate this forcibly, Dr. W. H. Tate reports the following case in the *Peoria Med. Mo.*, May, 1885:

On February 24, 1885, whilst Mrs. G., an old lady who died of apoplexy, was being washed for interment, one of the ladies who was present was called upon to assist in cleaning the body, and having previously a small scratch on the ring finger of her right hand, but not regarding it, happened to get some of the watery discharge that flowed from the bowels of the subject, into the abrasion. On the following day it was observed that the finger had assumed a red appearance, and also slight pain or smarting. In a day or two more the pain and redness had increased to an alarming extent, extending as far up as the shoulder and back of the neck.

Having poulticed it with various kinds of poultices, and getting no relief, after a delay of three or four days, Dr. T. was requested to prescribe for the hand. He ordered a flaxseed meal poultice to be applied, saturated with a ten per cent. solution of permanganate of potash, which was kept up for several days.

Good results were manifested after the second or third application, and in a week or ten days the hand was restored to its former condition and usefulness.

Glycosuria in Phthisis.

A point that will prove interesting to observe, and one that may ultimately lead to some practical therapeutic results, if a sufficient number of observations are recorded, is suggested by a short communication from Dr. M. Greenwood in the *Brit. Med. Jour.*, June 13th. He says:

For some time past I have frequently found sugar in the urine of phthisical patients. At first I thought this was but a coincidence, but latterly have begun to ask myself the question whether, in advanced phthisis, sugar is not invariably present in the urine. During the last three months, of five patients who died with this disease, I only failed to find sugar in one case, and in that there was probably extensive kidney-disease, as was shown by dropsy with albuminuria. The test I have always employed has been Fehling's, and the chief disturbing element in my analyses has usually been the presence of abundance of lithates. My results, however, I have often checked by testing in the same way some other sample of urine rich in lithates, where I did not suspect sugar, and comparing carefully the results obtained from each. I have referred to numerous works on medicine, but can find no account of any glycosuric tendency in phthisis, so that I should be glad to learn if my observations that have been noted previously, are merely accidental, or the results of error in analysis.

I may add that I have often discovered sugar in the urine in cases of respiratory embarrassment from acute pulmonary disease, as, for instance, in severe cases of bronchitis, and in pleurisy with effusion. In these, however, there has always been an excess of lithates.

Eczema of the External Ear.

Dr. W. R. Amick tells us in the *Cincinnati Med. Jour.* that in these cases the first thing to be done is to cleanse the parts thoroughly and remove the crusts. It is damaging to the physician's reputation, and useless to the patient, to make the applications on these crusts. We might as well place the salve on the boot over the location of the callosity on the toe, and expect the corn to be removed. We can not please the officials by patting the custom-house. They expect something more substantial, situated a little nearer *at hand*. We must locate our treatment closer to the seat of the disease than the top of these concretions.

In children these crusts are best softened by the use of a poultice, or of cottton wet in warm water. The object is to keep some moist and warm substance in contact with the crusts until they are softened. After they have been removed a good and convenient application is boric acid and vaseline, in the proportion of one part of the former to four of the latter. If this causes pain or irritation, you may suspect impurities in either the acid or the vaseline. This application, even without internal treatment, will frequently relieve the smarting and irritation that comes from the abrasions upon the auricle and side of the face, and cure the disease. It must not be forgotten that the most important factor is *thorough cleansing of the diseased parts* before the applications are made.

Unusual Case of Fatal Peritonitis.

The following case, which Dr. Norman Reid reports in the *Brit. Med. Jour.*, May 30, 1885, is sufficiently out of the ordinary run to warrant reproduction:

At 10 p. m. he was summoned to a man, with the following history: He was fairly temperate in habits, and had always enjoyed good health, with the exception of a slight attack of dysentery three years ago; he, however, since suffered from dyspepsia and constipation, necessitating care in his diet. He had, a short time before he saw him, eaten freely of veal, mince pie, plum pudding, etc.; and, shortly afterwards, was seized suddenly with intense pain in the abdomen. When he saw him, he was doubled up in great agony, and pressing his abdomen. Examination revealed nothing save great pain and tenderness in the umbilical region. He gave an inhalation of chloroform, and a hypodermic injection of half a grain of morphia. The next morning, when he saw him, he had symptoms of peritonitis; he died the same evening. The necropsy showed three strictures of the small intestine (jejunum); in front of the third was a perforation at the site of an old cicatrized ulcer. Through this perforation, about a dozen currants had escaped into the peritoneal cavity. The case is interesting from the difficulty of making an immediate diagnosis, and also from the unusual position of the ulcers and strictures. It would be interesting to know, if this lesion could have been diagnosed, what good, if any, might have been done by abdominal section.

Desquamation in Scarlet Fever.

Mr. George Smith states in a note in the *Bristol Medico-Chirurgical Journal*, that he has for several years been in the habit of having his patients sponged over the whole surface of their bodies twice a day—commencing, as a rule, about a week from the appearance of the eruption, and continuing the process until desquamation is complete—with a mixture of one ounce of oatmeal to one pint of boiling water. The solution must be made fresh every day, and used tepid, or at such a temperature as may be comfortably borne by the back of the finger. His reason for using this particular form of scalded, not boiled, oatmeal, is that the gluten in it sticks the scales to each other and to the surface of the body, thus allowing their removal, from one sponging to another, without the ordinary risk of infecting either atmosphere or clothes, and greatly lessening the risk of spreading the disease. Secondly, this same gluten fills up the cracks of the new skin and protects it from cold, as, patch after patch, it becomes bare, and thus greatly lessens the risk of the dropsy which often follows this disease.

Permanganate of Potash Baths.

In June, 1879, a well-developed child, two years of age, was brought to Dr. Hüllmann (*Archiv. für Kinderheilk.*, Band vi., Heft 3), covered with eczema and impetigo. He had been sent from Berlin to Halle to try the baths there, but after three weeks he was worse instead of better. He was therefore prescribed an immersion-bath of permanganate of potash, of the strength of fifteen grains to a pail of water, the child to remain in it until the fluid began to turn brownish. Fourteen days afterwards he was cured. Since then, Dr. Hüllmann has used the remedy both in adults and in children, and mostly with good effect. He has not confined its use to eczema, but has employed it also in prurigo, intertrigo, and the desquamating stage of measles, scarlatina, and varicella. When the skin is much covered with scales or scabs, it should be well brushed with soap-and-water first. For convenience of use, he keeps a concentrated solution made with hot water.

The Intravenous Injection of Milk.

That we may have a clear and definite idea in reference to this therapeutic procedure, we quote the conclusions of an excellent paper on the subject by Dr. Charles E. Jennings, in the *Brit. Med. Jour.*, June 6, 1885:

1. The intravenous injection of a small quantity of newly-drawn milk is harmless.

2. Large injections of milk are fatal, with polyuria as the chief symptom.

3. The employment of impure or stale milk is most dangerous, on the probability that septicæmia will follow the operation.

4. The operation is to be recommended in the later stages of cholera, enteric fever, phthisis, and pernicious anæmia, as a substitute for the transfusion of blood; and, in short, in all cases where transfusion of blood is indicated on nutritive grounds, but where a blood-donor cannot be procured, or where this operation is, for other reasons, impracticable.

Cocaine in Opening Buboes.

A correspondent reports this case in the *Med. Age*, May 25:

"G. L., æt. 35, had syphilitic bubo, leaving extensive sinuses, which ran in different directions down the thigh. Time gave no indication of their closing, and I concluded to open them. The party did not bear chloroform, and it was decided to give cocaine a trial. A four per cent. solution was injected into the fistulous canals and held there about five minutes. The effect was elegant. Where pain was excessive from exploring with a slender probe before using the cocaine, after using I passed a grooved director without sensation, and the knife caused the smallest possible amount of pain—"less than a pin scratch," to use the words of my patient. I opened up between eleven and twelve inches of fistulous canals."

Special Report.

OPHTHALMOLOGY.—NO. XIX.

BY CHAS. S. TURNBULL, M. D.,
Of Philadelphia.

(*Concluded from page* 24.)

Glascott. *Case of Traumatic Aneurism of the Left Orbit Cured by Compression of the Carotid Artery of the Same Side.* Oph. Rev., vol. ii., p. 193.

Glascott describes a case in which *exophthalmus followed a blow* on the left side of the head. A large, strongly pulsating vessel was discovered at the inner and upper angle of the orbit. A murmur could be perceived isochronous with the cardiac systole. Compression of the left carotid, performed by the patient himself, with the assistance of a suitable compress, caused the exophthalmus to disappear in three weeks.

Noyes. *Ocular Tumors.* Transact. Am. Oph. Soc., 1882.

Noyes removed a spindle-cell sarcoma which originated from the periosteum of the orbital floor, and extended to the inner half of the lower lid and the conjunctiva of the lower part of the globe. The eye was preserved, with a moderate amount of vision. A relapse occurred in the præ-auricular region, and the patient died in six months.

Lubrecht. *A Case of Pulsating Exophthalmus.* Deutsche Med. Wochensch., 1883, No. 35.

Lubrecht saw an exophthalmus develop in the right eye of a man, aged forty-nine, after a severe fall upon the head. Pulsation synchronous with the cardiac systole was noticed. No murmur could be heard by auscultation. The exophthalmus disappeared after ligation of the common carotid.

Eales. *Uniocular Reflex Iridoplegia Associated with Necrosis of Orbital Roof of the Same Side, with Double Optic Neuritis.* Oph. Rev., vol ii., p. 225.

Eales observed double optic neuritis and fluctuating swelling above and to one side of the right eye, after a violent blow upon the right temple. The spot was incised, and a piece of bone as large as a quarter of a dollar, and belonging to the external angle of the superior orbital roof, was removed. A fistula soon formed in the neighboring bone, and the neuritis gradually but surely retrograded.

Sedan. *La Tenonite Rheumatismale.* Rec. d' Oph., 1883, 337.

Sedan observed an enormous swelling of the lids in a patient who suffered from rheumatism, and who applied to him at first for violent headache without any visible alterations in the eyelids or globe. He scarified the lids at the external commissure, and saw a decided improvement, after persistent slow exudation of a serous fluid.

Gradenigo. *Massage in Ocular Therapeutics.* Annali di Ottal., vol. xii., 1.

Gradenigo resorts to massage not only in diseases of the lids, but in those of the eyeball which are associated with increased intra-ocular pressure. Massage was of great help to him, in addition to other cases, in a case of severe tenonitis, in which the eyeball protruded to a marked degree, and was totally immovable, the cornea had lost its sensibility, and the retina even quantitive perception of light.

Bono. *Rare Cases of Transmission of Blennorrhagia to Eyes.* Gaz. delle Clininiche, vol. xix., p. 14.

Bono reports three cases of blennorrhœa of the conjunctiva in adults who had been infected by a third person. The first case was that of a young lady who kissed and embraced, after a long absence, a brother who was suffering from blennorrhœa of the urethra; the second was that of a boy who slept in the bed of a patient suffering from gonorrhœa; whilst the third was that of a workman from whose eye a friend, affected with gonorrhœa, removed a foreign body.

Simi. *On Purulent Ophthalmia*, Annali di Ottal., vol. xii., p. 1.

Simi has tried every one of the antiseptics recommended of late years for suppurative inflammation of the conjunctival sac, and speaks very favorably of resorcin, because it not only acts antiseptically, but has the least chemical action upon the tissues of the eye. Nevertheless, the results which he has had with antiseptics of all kinds are not one whit better than those obtained with the old classical treatment of silver nitrate.

Panas. *Conjunctivite Rheumatismale.* Acad. de Méd., May 1, 1883.

Panas believes that cases of rheumatic conjunctivitis, such as Perrin describes, are to be accepted with a great deal of reserve. For himself, he has never seen any such cases. The purely rheumatic forms are very benignant; in malignant forms we ought to be able to exclude blenorrhœa and granulations.

Perrin. *Conjunctivite Purulente.* Bull. de l' Acad. de Méd., Nos. 16–19, 1883.

Perrin answers Panas by reading the history of a case carefully observed by De Belval, of purulent rheumatic conjunctivitis in a young man, without any granulations.

Robert. *Conjonctivites Catarrhales avec Arthrites Consécutives.* Rec. d' Ophth., No. 7, 1883, 311.

Robert describes six cases he had observed within thirty-three days, in which an acute conjunctivitis was followed by an affection of the joints which bore great resemblance to arthritis blenorrhagica. The particular type of disease is developed during very damp weather, in persons that are predisposed to arthritis by reason of their lymphatic diathesis and hereditary influences.

Diphtheritic Conjunctivitis, according to Potu. Théses de Paris, 1883, is simply the ocular expression of a constitutional affection. A conjunctiva affected with catarrh or blennorrhœa offers only a place of less resistance upon which the general constitutional affection can spread itself. Pain is generally absent in diphtheritic conjunctivitis; if it should, however, be present, it indicates that the globe itself is also affected. The treatment consists in local cold, and the exhibition of tonics.

Goldoni. *A Case of Diphtheritis of the Conjunctiva and Tonsils, together with Facial Erysipelas, Promptly Cured by Salicylic Acid.* Gaz. d' Ospit., anno iv., No. 33.

Goldoni treated a case of diphtheritis in a man æt. thirty-two years, with large doses of salicylic acid and local cleanliness alone. The disease, which developed itself in the eye and then affected the throat, and to which facial erysipelas associated itself on the third day, reached its acme on the sixth day, and had wholly disappeared on the eleventh, without leaving any trace whatsoever on the cornea.

Talko. *The Caustic Action of Calomel upon the Conjunctiva. Hemorrhages from the Conjunctiva.* Medicum, part xi., 1883. Goldscheider. Berlin Klin. Wochenschr., 1883, 42.

Talko and Goldscheider report several cases of caustic action after insufflating calomel into the conjunctiva. Goldscheider cannot offer any explanation for so rare a result. But he suspects that calomel in connection with the sodium chloride in the lachrymal secretion may exert a caustic action.

(It is a well-known fact that most samples of calomel contain more or less free corrosive sublimate, and this it is that has a caustic effect upon the eye, especially when carelessly dashed into the eye in lumps, instead of being insufflated as a powder.—C. S. T.)

Sattler. *The Jequirity-Ophthalmia, a New Infectious Disease.* Wiener Med. Wochensch., 1883, Nos. 17–21. Klin. Mon. f. A., Band xxi, page 207; Annal. d' Ocul., tom. xc., page 29.

Sattler examined the ophthalmia produced in man and rabbits by the jequirity seeds, and found that it differed in remarkable and essential points from any other artificial inflammation. The ophthalmia bears the greatest possible resemblance to an acute infectious disease, and approaches in many respects acute conjunctival blennorrhœa, particularly those severe types in which the conjunctiva is grayish, and exhibits a surface covered with a coagulable exudation.

Selitzky. *Iodoform in Trachoma.* Med. Wjestnick, Nos. 17 and 18.

Selitzky recommends the use of iodoform in ointment form in trachoma; he also uses other remedies at the same time. Under this treatment he has seen trachoma entirely disappear.

Pereyra. *On Some Therapeutic Uses of Iodoform.* Le Sperimentale, anno 37; fasc. 3.

Pereyra has employed iodoform, pulverized and in ointment (1 to 8), in more than 100 cases. Its action is not satisfactory in conjunctival affections; it has no influence upon pannus, but in ulcers of the cornea it is of the greatest value. The author asserts that iodoform also possesses a myotic action, diminishes intra-ocular pressure, without, however affecting the accommodation. Two cases of chronic glaucoma with inflammatory relapses were cured by iodoform treatment, *i. e.*, the pain decreased and the eye became more quiet.

Saltina. *Iodoform in Ocular Therapeutics.* Gazz. d. Ospit., anno iv., Nos. 48, 49, and 51.

Saltina also used iodoform in phlyctenular conjunctivitis, blenorrhœa neonat., in trachoma, pannus, etc., but did not obtain any remarkable results. This remedy is most valuable in corneal ulcers. Although Saltina was enabled to achieve unexpectedly brilliant results in four severe cases of hypopyon-keratitis, he does not regard iodoform as the sovereign remedy in this form of disease, and believes that he could have obtained the same results by other methods of treatment. Iodoform has no value in parenchymatous keratitis.

Vassius. *On the Use of Iodoform in Ophthalmic Practice.* V. Graefe's Archiv., band xxix., 1, p. 297.

Vassius recommends iodoform in all ulcerative processes of the cornea, especially in ulcus serpens; also in all superficial and deep injuries of the conjunctiva and cornea; finally as an antiseptic in wounds of the sclerotic.

Alker. *On the Therapeutical Value of Iodoform.* Inaug. Dissert., Giessen., 1883.

According to Alker, iodoform is well borne by a majority of patients. It is of especial benefit in all ulcerative processes of the cornea, particularly in the infectious forms of hypopyon-keratitis, although there are cases in which neither iodoform nor Saemisch's operation can prevent total suppuration of the cornea. Iodoform is of great value, not only as an antiseptic, but also as an aseptic in all fresh injuries. It frequently clears up the cornea in the most brilliant manner in scrofulous and deeper-lying corneal infiltrations.

Galezowsky. *Iodoform dans les Ulcéres Rongeants de la Cornée.* Rec. d' Ophth., 1883, p. 349.

Galezowsky advises the use of iodoform ointment in the treatment of most ulcers of the cornea. At the same time, however, the usual remedies are to be employed—atropia, eserine, etc. Several cases are described.

Makrocki. K. M. f. A., Band xxi, p. 323.

Makrocki describes *Three Cases of Extraction of Cysticercus from the Subconjunctival Tissue in Children.* The capsule of the cysticercus was found

to consist a framework of connective tissue composed of thick fibres of connectfve tissue, running lengthwise, and crossed by elastic fibres. The outer and inner surfaces were partially covered with a capillary mesh-work, which was rich in anastomoses. The external surface showed considerable endosmosis and exosmosis of white blood-corpuscles, which, toward the inner surface, had been transformed into epithelial cells.

Creus. *Operation for Pterygium.* Eco de la Clinica, 1883.

Creus operates upon pterygium by loosening the vertex as far as 3 mm. beyond the margin of the cornea, then turns the vertex over to form a duplicature in such a way that the two bleeding surfaces touch. So soon as they are accurately adjusted, sutures are applied.

Couzon. *Contribution á l' étude de la Keratite Interstielle dans la Syphilis Héréditaire et dans la Syphilis Acquise.* Thése de Paris, 1883.

Couzon asserts that interstitial keratitis is a frequent result of congenital syphilis, while occasionally it is seen in acquired cases of this disease. Rheumatism may also excite attacks of interstitial keratitis.

Martin. *Sur le Rapport qui Exista entre Une Variétié de la Keratite Grave, dite Scrofuleuse et l' Astigmatisme de la Cornée.* Annal. d' Oculistique, Tom. xc., p. 14.

Martin brings forward a new form of keratitis, which he calls astigmatic keratitis. We frequently see in scrofulous persons, between the age of six and twenty, an extremely obstinate keratitis, which is due, as Martin insists, to a corneal astigmatism. Any corneal astigmatism is corrected by varying degrees of accommodative energy in the two main axes ; but this very energy, according to Martin, produces the corneal inflammation. Astigmatism, therefore, is the cause of corneal affection, and the author endeavors to prove the fact. In order to cure the keratitis, the accommodation in both eyes must be paralyzed. Relapses can be prevented by furnishing proper correcting glasses, while in the very same way the appearance of astigmatic keratitis can be prevented.

Frank. *Case of Partial Keratoconus, with a Remarkable Change in the Refraction Following an Injury.* Maryland Med. Jour., September, 1883.

Frank reports the following case: The patient ran against a ladder. The globe was ruptured at the sclero-corneal margin, and a hernia of the iris ensued. This was removed close to the globe with scissors. The refraction of the eye then began to alter, and finally sight became $\frac{10}{15}$ with $\bigcirc + \frac{1}{6}$ sph. $\bigcirc + \frac{1}{6}$ cyl. axis 56°. The author would thus argue in favor of iridectomy as a remedial measure in keratoconus.

Hirschberg. *On Congenital Pigmentation of the Sclera, and its Pathogenetic Significance.* V. Graefe's Archiv., Band. xxix., 1, p. 3.

Hirschberg publishes three cases of melanosis of the sclera, in two of which the eye had to be removed on account of an intra-ocular tumor. In his opinion, melanosis of the sclera indicates a certain predisposition to subsequent development of a tumor in the eye, just in the same way as congenital pigmentation of the skin may, in old age, form the starting-point of melanotic growths.

Higgins. *Gummata of the Sclerotic.* Brit. Med. Jour., February, 1883, p. 247.

Higgins reports three cases of gummata of the sclera. The first one recovered after a treatment of several months' duration. In the second, the tumor covered both the inner and outer surface of the sclera, and had caused detachment of the retina. The third resisted treatment for a long time.

Hirschberg and Birnbacher. *Congenital Lipomatous Dermoid, in and behind the Equatorial Region of the Eyeball.* C. f. A., 1883, Band vii., p. 295.

Hirschberg removed from the lateral portion of the sclera a tumor 18 mm. long, 10 mm. broad, and 7 mm. thick, which proved to be a dermoid tumor with fatty tissues in the deeper layers.

Danesi. *Coloboma of the Iris.* Boll. d' Ocul., vol. v., 9, March, 1883.

Danesi describes a congenital coloboma of the iris in which the corresponding portion of the ciliary processes was also absent. The choroid was intact, but numerous deposits of pigment were found in the fundus. V.=$\frac{1}{3}$ with —20.

CORRESPONDENCE.

Depressed Fracture of Ribs, with Wound of the Diaphragm and Left Lung.

EDS. MED. AND SURG. REPORTER:—

Reading the report in the last polyclinic by De Forrest Willard, M. D., of fracture of ribs with wound of liver, lung, and diaphragm, has induced me to submit the following case. I regret an autopsy was refused, hence my diagnosis was not confirmed.

June 1, 1885, was called to see J. G., colored, aged forty-five years, weight 170 pounds, who had just fallen a distance of twenty feet, striking upon a pile of lumber. Upon examination, found fracture of seventh and eighth ribs on left side, and fracture of two metatarsal bones. Patient in profound shock. Morphia and ether administered hypodermically. Ordered him removed to his

home, where I saw him one hour later. Slight reaction had taken place; dyspnœa was alarming; great pain in epigastrium, with marked retraction of the abdominal wall. Stimulants and opiates administered freely. At four o'clock p. m., six hours after injury, there was full reaction; pulse, 120; temperature, 100°. Physical examination revealed pneumothorax, together with considerable hemorrhage into the pleural cavity, gurgling rales, and well-marked metallic sound.

There was some tympanites, patient expectorating bloody mucus, nausea and hiccough distressing. Diagnosis—Fracture of seventh and eighth ribs, with slight depression of outer fragments, wounding the diaphragm and penetrating the pleural cavity, entering the base of the lung. Treatment.—Morphia hypodermically, and chest bandage.

June 2, 7 a. m., breathing not so labored, tympanites increasing, vomiting relieved, pulse 125, weak and gaseous, temperature 102°. 12 m. No appreciable change. 7 p. m. Consultation held, agreed upon the above diagnosis, beef and whiskey enemata suggested and prescribed, digitalis given by mouth, but rejected.

June 3, 7 a. m. Tympanites still increasing, pulse feeble, active stimulants administered by rectum and hypodermically. 12 m. Pulse 100, and stronger than at any time since the accident, hiccough annoying, no other change remarked. 6 p. m. Patient died suddenly.

The symptoms leading me to diagnose wound of diaphragm were hiccough, pain in epigastrium, marked retraction of abdominal walls at first, and subsequently tympanites.

Richard Douglas, M. D.,
Nashville, Tenn.

News and Miscellany.

The Kentucky State Medical Society.

PROCEEDINGS REPORTED BY ALLEN KELCH, M. D.

The Kentucky State Medical Society held its thirtieth annual meeting at Crab Orchard Springs on the 24th, 25th and 26th of June. The attendance was large, and the meetings full of interest.

The regular order of proceeding was begun by the report of the Committee on the Practice of Medicine, Dr. Wm. Bailey, of Louisville. After a few introductory remarks, Dr. Bailey spoke in substance as follows:

"In the first place I will mention my experience (I suppose it is likewise the experience of all of us) in having my office table cumbered with new preparations in pharmacy. I think this has been carried to an extent that has necessarily made it a nuisance, and that it has utterly failed to meet the purposes of those who have distributed them. I confess, at the beginning, that I have not had the courage to even uncork a tithe of them, and have become familiar with scarcely any of them. I think that the principle as well as the practice is at fault. It occurs to me that the cart is before the horse; that the physician should go before, and, after proof of value, demand of pharmacy certain preparations of drugs, or certain combinations of them eligibly prepared, instead of having them urge you to prescribe medicines prepared by their formula. It seems to me to be more of commercial policy prompting the multiplication of these new remedies than either necessity or convenience. I may be mistaken, but I am inclined to the belief that the other course would equally redound to the material interest of those who are thus concerned. I would ask you what proportion of these preparations that have been so widely dispensed in the last five years are now among the reliable means of combatting disease? An evil accompanies the method that is inseparable from it. The tendency is to induce the people at large to buy and take these preparations without medical advice. It fosters a disposition altogether too general of indiscriminate medicine taking. I would suggest that if an enterprising firm desires to put before the world a new remedy of value that it would be better for all concerned to have it placed in sufficient quantity to be used by public institutions, at the hands of competent men, to note and record its effects in a large series of cases, so that the practitioner might have some reason for confidence in its administration.

"In this way the good will not suffer loss and the useless will not disappoint. Too many of us, I suspect, are daily watching the medical journals for our prescriptions, hoping to get the reliable to replace that which has failed us. Would not this in the long run even pay those engaged in manufacture?

"I do not wish to underrate the importance of pharmacy or decry the effort being made to render medicines more elegant or eligible in preparation, for I think much has been done in this line and still much remains to be done.

"You might answer that all of these come to us accompanied by a long list of testimonials. True, but we know how and from whom such testimonials are obtained. No doubt to some it is flattering to their ambition to be approached, with the statement that testimonials are wanted only from the leading men in the profession, and others are delighted to see their names in print, scattered broadcast over the entire country.

"Do we not need to cry halt? and to become more familiar with the reliable drugs already in use? The efficiency of any arm in service is very largely due to the skill with which it is used, and this can be acquired only by constant drill and exercise.

"I have said this because my report should properly consider materia medica as well as practice."

Succeeding this, Dr. Bailey spoke of the all-absorbing question of cholera. He expressed himself as skeptical concerning the "comma bacilli" theory of the origin of the disease, and while ready to accept any theory that admits of demonstration, he was yet inclined to think that in climatic and telluric conditions we must yet look for the most potent factors in the causation of the disease. His grounds for skepticism will, perhaps, be better understood from the following remarks, which occurred in his paper:

"We have no apprehension of cholera in winter time, no matter how many infected ships reach our shores. We find persons arguing that season has nothing to do with it; that cholera prevailed in Russia amid ice and snow, which may have been true, for they forget how that the peasants

of Russia live in adobe houses, kept up to a temperature that would satisfy the most cold-blooded. Why don't they cite cases in our own country, in our own experience, to substantiate the statement? The thorough conviction of the late Prof. Theo. S. Bell was that this disease was altogether due to telluric or climatic influences, and I am constrained to think that few men in the present age have given such undivided attention to the etiology of this infectious disease as he. I do not wish by this proposition to invalidate the claim of the germ theory of the disease, but to put it alongside of malarial fever, yellow fever, and the plague.

"Some other propositions dependent upon this one I would like to discuss if I had time, particularly the subject of quarantine as practiced in this country. Some curious things are done in this business, and apparently without the inconsistency striking the average mind at all. We establish a quarantine, no matter where, and place doctors and others in charge. Who protects the doctors and others that come in contact with those subjected to the quarantine? How would this practice, in stamping out variola, satisfy us? Establish a quarantine against the small-pox, and place in charge men who are not exempt by virtue either of having had the disease or having been vaccinated. What would you think of that, and yet in what is it different from this?

"I do not insist that the cause of cholera is not portable, but I do not believe that the cause of cholera is propagated by contagion. I would insist upon the quarantine of infected vessels or cars to the destruction of the germ or specific cause, whatever it may be.

"I like best the methods practiced by Dr. Joseph Holt, of the New Orleans Board of Health.

"Improved sanitation should be the watch-cry against such epidemics.

"I have not the time to discuss the symptomatology or the management of the disease. The impress of the poison is chiefly, in my judgment, upon the nervous system, as it is in malignant intermittent fever and yellow fever. Absorption from the alimentary canal and excreta by the kidneys are suspended. Treatment is successful only when applied in the early stages. Mortality is not materially affected by any means in our power after the stage of collapse. Morphia and atropia, hypodermically, meet the indications best.

"My imperfect paper is intended to be suggestive and not exhaustive, and if your wisdom is stimulated to develop by discussion more important facts, I shall feel myself content.

"I have stated what were my preconceived opinions; that now I am inclined to the plausible germ theory, and stand ready to bow to the inexorable power of logical demonstration when it shall be made."

Discussing the paper, Dr. Dudley S. Reynolds said:

"Dr. Bailey might have found less difficulty in formulating his skepticism if he had made it plausible. The microbes which cause cholera never appear in the blood of the patient nor in any secretion. They operate entirely upon the lining of the intestinal canal. By destructive action upon the epithelium, abrasions follow which drain so much of the fluids from the body as to rapidly deplete the patient, who presently reaches the stage of collapse, and dies without any evidence whatever of the introduction of any sort of matter into the system. On the contrary, it is what has been withdrawn from the system through the abrasions or excoriations of the walls of the intestinal tract, which robs the patient of the vital fluids. If Dr. Bailey would study the published reports of Dr. French, of Wilkes-Barre, Pa., and Dr. E. O. Shakespeare, of Philadelphia, he would find perfectly conclusive evidence that the typhoid fever, which has prevailed with such disastrous effects in the town of Plymouth, originated in the contamination of the water-supply, by the discharges from a patient having that disease.

"No person who has studied the literature of the several epidemics of cholera which are known to have prevailed in different parts of the world will undertake to deny the influences of accumulations of fluid in filthy gutters and cesspools upon the water-supply, and the influence of this, in turn, upon the spread of the cholera. There is no comparison, as Dr. Bailey states, between the manner in which small-pox and cholera enter the system. Quarantine in the presence of small-pox prevents its spread, by limiting both the amount of poison and the number of susceptible people. In the case of cholera, the resting-place for the microbe prior to its introduction into the drinking-water, or its lodgment in the dew upon such vegetables as may be eaten uncooked, limits the chance of contact of the microbe with the vegetables, or the introduction of it into the water, provided only the aid of thorough sanitary police be employed for the thorough destruction of these cesspools or resting-places. In this way climatic and telluric influences may alone serve to propagate an epidemic of cholera, the air being powerless to carry it from one person to another directly. It must be swallowed, and this is generally through contaminated water."

Dr. McCormack, of Bowling Green, said:

"I very cordially agree with much that Dr. Bailey says in regard to the influence and importance of climatic and telluric conditions in the production of cholera. It seems to me that, admitting all this, the history of cholera in every country where it has prevailed teaches that there must be something added besides these influences. In those seasons when it has prevailed in parts of this country, other portions having like climatic and telluric influences exercising their influence have, when this other particular influence which we recognize as the specific cause of the disease was inoperative, escaped. I may mention a case where a negro coming from Lebanon, where the disease was prevailing in 1873, to Columbia, where no cholera had previously existed, was suddenly seized on his arrival at the latter place so violently that he died of the disease in a closet attached to a livery stable. The Monday following this occurrence was county court day. Many farmers from the surrounding conntry while in the city had occasion to visit the foul closet in which the negro died. In forty-eight hours afterward the cholera was epidemic throughout the county, the primary cases occurring in those who had visited the city and been in this closet.

"During the same year the cholera was im-

ported from the railway station to Lebanon, and prevailed at first in the families of some negroes, who lived on the banks of a ravine, the cases being confined to them for some time. Out of the wells from which they gained their water supply, and which were situated but a very short distance from their houses, water was hauled to the fair grounds and put in barrels for the use of the people attending the fair, and in the next forty-eight hours cholera was epidemic throughout Marion county.

"In Genoa, last year, contrary to what occurred in Marseilles and Toulon, the cholera made its appearance in the best quarters of the city. This was an inexplicable mystery until it was determined that the water supply of the city is derived from three companies, two using a large stream, and one using the water of a smaller stream. This smaller stream supplied the affected portion of the city. It was then discovered that not far above the inlet of this water supply the cholera had been prevailing among the miners located there, the filth from whose settlement was discharged into the stream. So far as we were able to gather the evidence in this way, from city to city, it all points to the existence of a specific cause, capable of transmission thus from one point to another, and it would appear that we can no more have cholera without this specific seed than we could expect to raise a crop of oats or wheat or barley without scattering the seeds upon the ground prepared to produce it."

Dr. J. B. Marvin said:

"There are one or two points in Dr. Bailey's paper I wish to call attention to. We have more than one kind of comma bacillus. Dr. Koch has conclusively proved that the comma bacillus which he describes is characteristically distinct from those which some observers have claimed to be inert. Klein claimed there was nothing in the theory, and to show his faith, publicly drank water containing the comma bacilli. But Klein was forced to admit, in a discussion with Watson Cheyne, that he was ignorant of the variety described by Koch.

"Now, another point with reference to the activity of contagion. At certain places along the Ganges river religious customs call for the assemblage of large numbers of people to drink and bathe in the waters. This is done with impunity and without cholera occurring until some arrival from Bengal, where the disease prevails, carries the specific poison to its waters. This once done, thousands at once fall victims to the disease. At Mecca this experience is repeated almost every year among the hosts who gather there to drink of the holy well. When some pilgrim arrives from an infected district and the water once becomes contaminated by the poison he has carried, thousands at once falls a prey to this fell destroyer."

The hour of meeting being late, at the conclusion of these remaks the Society adjourned to meet in the evening, when papers were read by the President, Dr. Pinckney Thompson, of Henderson, and by Dr. Williams, of Cincinnati.

Thursday Forenoon.

After the transaction of miscellaneous business the session opened by Dr. J. M. Matthews, Committee on Surgery. The scope of the subject being so great, his remarks were confined to the operations of recent attempt. On the subject of anæsthetics he spoke of cocaine and its applications to general surgery. Admitting its value in eye, ear, and throat practice, he had yet found that where a large amount of skin has to be cut the local applications of rhigolene by spray are equal, if not superior to it. After speaking of general etherization, and condemning the practice of rectal anæsthesia, he spoke as follows upon "Antiseptic Surgery:"

Antiseptic Surgery.

"Upon no subject in surgery is there so wide a difference of opinion as that of antiseptics. The Listerian method has been handled 'without gloves,' and although the attacking party has succeeded in routing it from the hospitals, etc., they find dissension in their own ranks as to what to substitute. The most prominent antiseptics in use are, viz.: Bichloride of mercury, iodoform, hydrate of chloral, subnitrate of bismuth, turf-dressing, boracic acid, eucalyptus oil, aseptol, naphthalin, listerine, etc., etc. In hospital practice bichloride of mercury perhaps heads the list. It is employed in all the great operations. The strength of the solutions is anywhere from one part of the agent to 1,000 or 5,000 parts of water. The question to be determined is, in what dilution can bacteric life exist. Koch decides that the spores are destroyed in a solution of one to twenty thousand parts; while others contend that they have detected them in much stronger solutions.

"Iodoform finds its greatest advocate in Billroth. Indeed, the German surgeons seem agreed upon this agent as the antiseptic par excellence. The most important question in its use is, can it be absorbed in sufficient quantity to produce poisonous effects? Several years ago I detailed my experience with the use of the drug to this society. I then mentioned that I believed the fears of the profession in regard to its use were not well founded, reciting instances where I had used it in large quantities in the rectum in cases of ulceration, cancer, etc. The packing of large wounds, as after resection of joints, etc., may not be advisable, yet it is practiced by some surgeons, notably Billroth. All in all, it may be regarded as one of the best antiseptics.

"*Turf Dressing.*—There are a few advocates of turf as a surgical dressing. It is said that its discovery was accidental, yet its application would seem to be theoretically appropriate. Healing under a scab is regarded as one of the best modes in the healing of wounds, and it is upon this principle that many syphilitics resort to the mud bath of Hot Springs. Turf is both an absorbent and antiseptic. A preparation of mineral earth, to be used for this purpose, is put up by the Natural Pharmacy Association of Baltimore.

"*Naphthalin.*—It is claimed for this agent that the power in preventing decomposition of organic fluids is remarkable, and that the appearance of bacteria and micrococci can be prevented in pus by the addition of a small quantity of it.

"*Listerine.*—Among the very best and safe stantiseptics is listerine. The more I use it the better I am pleased with it, especially so in large sup-

purating wounds. In such many of the other antiseptics are dangerous, but listerine is free from danger, and meets the indicated terms as well. It is a mild stimulant, a safe antiseptic, and free from any offensive odor. I will not take the time to discuss the other antiseptics."

He continued: "A question of great moment to the surgeon is, can he, while attending cases of pyemia, erysipelas, etc., by the use of disinfectants, prevent the contagion that is said to be communicable? Without stopping to discuss any theory in regard to contagion under these circumstances, I desire to quote the views of Prof. Volkman, as expressed in a letter to Dr. George F. French, of Minneapolis. He says: 'A surgeon who disinfects himself well can, immediately after making a post-mortem, undertake any operation known to surgery.' This is a strong saying of the eminent German, and very hard to believe."

After addressing a few remarks upon abdominal surgery, he passed on to the

SURGERY OF THE KIDNEYS.

"Certain operations for the relief of kidney affections are now regarded as justifiable, and are attended with success, viz.: nephrotomy, nephrolithotomy, and nephrectomy. The greatest trouble in cases requiring such operations, as renal calculus, is to tell of a certainty that it exists. All the typical symptoms may exist without the presence of the stone. The diagnosis is the most difficult part. Nothing is definite except exploratory incisions. Under what conditions this procedure is warrantable must be decided by the surgeon. It is certain that by its detection and removal the most absolute and perfect relief is given.

"*Thoraco Plastic Operation of Estlander.*—One of the most interesting diseases falling under the surgeon's care is empyema, the relief of which—I refer to the chronic form of the disease—is so very unsatisfactory. An operation is proposed by Estlander for the eradication of the sequela of the disease, viz., the obliteration of the suppurating cavity and the occlusion of the pleura fistulæ. It is the common custom with surgeons to treat empyema by the free incision and drainage and a free washing out of the cavity, together with disinfection.

"The results of such treatment are, in the main, satisfactory, in that fifty per cent. have recovered. But seventeen per cent. are followed by permanent fistulæ. Estlander's operation is intended to overcome this latter percentage. The indication for the operation is when the fistula has existed several months and resisted ordinary treatment; the contra-indication is the existence of tuberculosis, albuminuria, or great emaciation. If the latter exist without the former, I do not know that it should stand in the way of an operation. Large fistulous tracks around the rectum have been freely laid open by me in the emaciated subject, and the stoppage of drainage was of material advantage to the patient. As many as six ribs have been removed during the operation, but it is usual to remove two or three only, and this is accomplished by one incision. The details of the operation are very simple. The most favorable position is upon the lateral portion of the thorax, in the axillary line, the intercostal spaces being covered by the serrations of the *serratus magnus*. The length of the incision and portions of ribs removed depend upon the size of the cavity in the horizontal direction. The first and second and the eleventh and twelfth ribs are always left intact.

"For many statements contained in this paper I am indebted to the authors of the operations, who have been kind enough to answer questions and help me to arrive at satisfactory conclusions. In other instances the detailing of cases, by men who have performed the operations, has helped me materially. If nothing new has been added to our surgical knowledge by this report, I have succeeded at least in drawing your attention to those operations concerning which there has been much difference of opinion, and aided some little in their elucidation, I feel satisfied."

DISCUSSING THE PAPER.

Dr. M. F. Coomes, of Louisville, said:

"The most important point which now occurs to me is with reference to the speaker's words concerning abdominal surgery. It is a well-known fact that the tissues of the abdomen, and particularly of the intestines, are abundantly supplied with blood; in this respect being similar to the tissues of the face, and they, therefore, when other circumstances are favorable, heal readily and completely. For my own part, if I were suffering from a wound of the abdominal structures, and any hesitancy should be manifested on the part of the surgeon called to my side about opening up the abdominal cavity in order to determine and, if possible, remedy the mischief done, I should unhesitatingly insist upon its being done at once.

"With regard to the use of iodoform, I would say that my experience with the drug has been somewhat peculiar. I have used it in two instances in the form of insufflation upon the throat. In each case, within a few minutes after the application, the patients began to grow dizzy, complaining of a feeling of weight in the epigastrium, the pulse being quickly increased in frequency. One of these parties was a physician, and he, of course, knew what the medicine was, and suspected the cause of these sensations. He assured me that he repeated the dose again and again, always with uniform results."

Dr. Williams, of Cincinnati, said:

"We have been in the habit of using cocaine a great deal in painful affections, in paracentesis of the drum membrane, etc., and with uniform satisfaction. We have sometimes used it in enucleation of the eyeball, and we have come to the conclusion that none of the American preparations are equal in efficiency to that made by Merck, of Darmstadt. There is no amount of experience in this world that has been entirely satisfactory to me in any department of work that I know of in this world, but at the same time there is no kind of doubt that the introduction of this local anæsthetic has proved a very valuable addition to the means we already possess for the relief of human suffering. It is not applicable to all operations, however.

"Dr. Sattler, who is associated with me, yesterday removed a tumor from the temple of a young woman, and he attempted to produce an-

æsthesia by cocaine, using three or four injections into its structure. I don't know how much more she would have complained at the operation without the influence of the drug, but she certainly complained enough with it. In the extraction of cataract we use it now altogether, without resorting to general anæsthesia.

"Dr. Vance said he had made frequent applications of it to reduce the pain of small operations, adding first applications of the drug as the operation progressed. In this way he had found it very satisfactory.

"Dr. Roberts said he had used it frequently in operating upon small tumors; in one case the operation was followed by the application of caustic and no pain was complained of. He had used it also in fissures, but without any good effects. In irritation or inflammation of the prostatic gland he had had some happy results.

Dr. Scott said:. "Several points in this paper struck me with much force, among others that a surgeon can pass from the post-mortem table to the side of a woman in ovariotomy with no danger of carrying infection to the woman being operated upon. How far would any of us feel justified in carrying practice like that? We all feel it improper to expose ourselves to any such disease as puerperal fever, traumatic fever, or erysipelas, while we are expecting to be called to a case of confinement, and I am led to ask how much can we measure our own personal responsibility, how far can we in justice expose ourselves to these diseases we regard as infectious and contagious before going to a case of confinement, and how far can we carry disinfection to render it safe after seeing such a case to attend one of confinement?"

Dr. Reamy, of Cincinnati, a well-recognized authority on obstetrics and gynecology, said: "The paper just read was extremely interesting and instructive to me. So far as the statement that it is entirely safe to pass from the dead-house to the operating-table is concerned, I can concede that, because it is a well-known fact that the germs of decomposition which play havoc in the dead-house are not the germs that threaten danger to the living. It is a question of greater importance to determine if it it is not more dangerous to pass to the lying-in chamber from the house of the living. I have no hesitation, gentlemen, in saying that if a man is in constant attendance upon a case of erysipelas or traumatic or puerperal fever, unless he is in a position to be able to change his clothing, even to his shoes and socks, and be shampooed by his barber, and take a bath, he ought not to approach the lying-in chamber. But granting that a man can so disinfect himself, it is yet safe to say that a man who is in attendance morning, noon, and night upon these contagious diseases is not a suitable person to attend a case in obstetrics. But can a man subject himself to sufficient disinfection to justify him in attending a case of obstetrics after exposure in the sick-room of a patient suffering from puerperal fever? I believe he can. I was in consultation very recently at Glendale, O., in a case of puerperal septicæmia where at my last visit it was necessary for me to make complete examination and expose myself in this way to the utmost. The case proved fatal and the exposure was complete. On the next evening I was summoned to attend a case of confinement. As soon as I arrived home from the case of which I speak, my clothing was completely removed from head to foot; I took a bath, and followed it by another containing as much carbolic acid as I felt inclined to bear; went to my barber, and in the evening retired to the house of the case I speak of, where I remained almost constantly for the next twelve hours, and no bad results whatever attended the case. I certainly could not have felt justified in going without taking these precautions. It does not do in these cases to simply wash the hands with great care in solutions of carbolic acid and water."

Papers were then read by Drs. Vance and Mcmurtry, abstracts of which, with the discussion they elicited, will appear in a following report.

(*To be continued.*)

Purification of Drinking Water.

The average healthy adult man takes into his system four and a half pounds of water daily, and with it too often a dangerous quantity of foreign matter and disease-producing germs. In very many homes during the summer months, water that otherwise would nauseate the drinker, is made cold by ice, and then is hastily swallowed, the coldness masking its offensiveness. Unfortunately for the health of the consumer, the addition of ice does not render the impurities in water innocuous, but often adds to it its own contribution of disease-germs. The only safe-guard to the consumer is in giving his personal attention to the filtration of the water used in his household. Water slowly percolated through crushed vegetable charcoal will escape from it not only cleansed of particles held in suspension, but also of organic and other matter. The cheapness of charcoal is such that it is obtainable by all classes, and when soiled, a fresh quantity can be substituted at trifling cost. The most effective filtration is obtained by placing crushed charcoal in an earthen vessel, so arranged as to compel the slow passage of the water through it, as all efforts at rapid filtration have proven inefficient. Only wooden spigots should be used in drawing off the water. A reservoir for the filtered water, with a separate ice chamber, will permit the water to be sufficiently chilled and keep all ice impurities out. Such a contrivance requires but very little room, is easily cleaned, and renewed, and is efficient in freeing water from impurities.—*Dr. Edwin J. Howe, in American Agriculturist for July.*

Danger from Phthisical Farm Laborers.

The Paris correspondent of the *Brit. Med. Jour.* (May 16, 1885), writes: "A farm at Charenton has furnished somewhat startling evidence of the transmissibility of tuberculosis from man to domestic animals. One of the farm-servants, who was phthisical and too weak to undertake fatiguing duties, was placed in charge of the poultry yard. He grew steadily weaker, and coughed incessantly, expelling a quantity of sputa, which the fowls were observed to swallow with avidity. In a few weeks the fowls began to die off. The owner of the farm sent one of the fowls to the veterinary school at Alfort. M. Nocard found that the lungs and liver were infested with tubercles about the size of a pea, and of a greyish-yellow color. In

a microscopic preparation, there were numbers of bacilli. The fowls were killed, and the poultry yard disinfected. A less honest farmer might have sent the tuberculous fowls to market, a probability which doubtless has been, and will yet be, a certainty not always easy to discover. The danger attending the consumption of diseased poultry or milk from tuberculous cows, indicates that a rigorous system of inspection ought to be organized for markets, farms, and poultry yards."

Items.

—Dr. H. V. Sweringen has been appointed pension examining surgeon at Fort Wayne, Ind., and re-elected health officer of Allen county.

—The Spanish Congress for the discussion of Hydrology and Climatology, which was fixed for October 1, 1885, has been postponed to the same date next year.

—The King of Greece has recently conferred on Dr. Morris H. Henry, of New York, the Gold Cross, and created him an officer of the Royal Order of the Saviour. The honor was conferred for services rendered to medical science, on the recommendation of the Faculty of the University of Athens.

—A foreign exchange says that powdered rice as a styptic remedy has a great effect on fresh wounds, much superior to oxide of zinc. By mixing from four to eleven per cent. of it with lint, and using the lint thus treated as a compress, it is very effectual and more valuable than subnitrate of bismuth, salicylic acid, or carbolic acid.

—If a saturated solution of hydrochlorate of cocaine in strong nitric acid be applied to the skin, instead of the painful smarting of the acid alone, a slight pricking sensation is the only sensory effect produced. An eschar is formed, but takes a longer time to appear than if the nitric acid be used alone. These results have been obtained by Messrs. Randolph and Dixon.—*Pharmaceutical Journal.*

—M. and Madame Victor Saint-Paul have given 25,000 francs to the Académie de Médecine, to be awarded as a prize to any one who can discover a remedy, to be recognized by the Académie, as efficacious in diphtheria. Until the remedy is found, the interest paid on the money is to be awarded every two years to those whose works and researches on diphtheria are recognized by the Académie as the best. This prize is open to competitors of all nations.

—Prof. G. Sée has observed in a large number of young men violent palpitations of the heart, which made him fear that they would be unfit for military service. Experience showed him, however, that the palpitations were not increased by exertion, and that, on the contrary, they tended to disappear gradually as the men got stronger. In these cases the palpitations were accompanied by a loud systolic murmur, which could be heard at the apex, but not over the large vessels. The heart was enlarged, the pulse sometimes irregular. In some cases there was dyspnœa or frontal headache. As regards the treatment, regular exercise, without fatigue, is to be enjoined; iodide of potassium and convallaria majalis sometimes do good.

—A case of excessive dilatation of the stomach is mentioned in the *Vratch*, which occurred in the clinic of Prof. Koshlakov, of St. Petersburg. The patient was a peasant, aged forty, and had been ill for three years. It was found that six litres of water could be introduced into the stomach without occasioning the man any inconvenience. The same journal records the case, by L. Scheffer, of a peasant, aged forty-nine, with intestinal obstruction, who, after the stomach had been twice washed out, passed a stool containing ascarides. Two grains of santonin were then given, with jalap, and about twenty round worms, which had been the cause of the obstruction, were passed.

—The *Lancet* says that from information published by the Immigration Office, Sydney, New South Wales, it appears that in the cities and larger townships of the Colony there is no lack of competent medical men, but in the newer and more remote districts they are too often conspicuous by their absence, and it is by no means unusual for the inhabitants of such places to advertise their willingness to guarantee a certain amount of income to a resident doctor. An experienced medical man, willing to "rough it" for a few years, will attain a competency much more rapidly than in England, especially if devoted to his profession and skilled in the treatment of complicated cases. Medical specialists possess a wide field in Australia, where institutions for the treatment of eye and ear diseases, etc., are practically unknown.

—To the British Gynecological Society, Dr. Lamprey described a case of double monstrosity. The patient had miscarried at the third month. She was 22 years old, and had had one child previously, who was born healthy. When Dr. Lamprey came to examine the ovum, he found it to consist of a double monster. The lower halves of the two sterna, and the whole of the abdomens, were united so intimately that, had the children arrived at maturity, and lived, it would have been extremely difficult for one of them to walk forwards without the other walking backwards. Or, supposing they walked sideways, the pelvis of each would have had to rotate in great measure upon the lumbar, or lumbro-sacral vertebræ, much more than could be accomplished. Had these fœtuses come to their full time, no doubt they would have caused a long, painful, and exhausting labor.

QUERIES AND REPLIES.

Please state in your valuable REPORTER the formula for glycerinum acidi carbolici, spoken of in June 20, MEDICAL AND SURGICAL REPORTER. S. N. ROWELL, M. D.

Ans.—Take of carbolic acid one ounce (avoirdupois), glycerine four fluid ounces (imperial measure), rub them together in a mortar until the acid is dissolved.

TUBERCULAR MENINGITIS.

BY HUGO ENGEL, A. M., M. D.,

Professor of Nervous Diseases and Clinical Medicine at the Medico-Chirurgical College of Philadelphia.

October 16, 1884, I was sent for in haste to attend the six year-old Mary K., daughter of a widow, whose husband had died two years before of pulmonary phthisis. On my arrival, the mother gave me the following description of her daughter's illness:

Mary had been a healthy girl and never suffered from any of the usual diseases incidental to childhood, until about a week previous to my seeing her. Then one morning she awoke earlier than was her habit, being seized with diarrhœa, which had since alternated with constipation. Her mother, however, had become alarmed mainly at the great change which she observed in her daughter's spirits. Mary used to be a very bright and somewhat wild girl; she never cared to sit still indoors, but always desired to play out in the air with other children. It was the most difficult work to induce her at nights to retire. Since her illness she often sat for hours quietly in her little arm-chair, appeared tired, and found no pleasure in joining the company of her playmates. And aside from all this, a peculiar listlessness had had come over her, so utterly at variance from her former vivacity, that her mother conceived the idea that some serious illness was beginning to operate within the child. How correct this opinion was the following will show.

The morning of the day when I was called, Mary had been particularly sleepy on awakening, and besides suffering from the diarrhœa, had greatly complained of headache. The least pressure seemed to augment the pain. When, after leaving her bed, she stepped across the room, her gait was unsteady; once or twice she appeared to reel, and cried out, "Oh, mamma, I am falling!" Her mother assisted her to a chair, and after dressing her persuaded her to partake of some food. Scarcely had Mary swallowed a mouthful of milk and a piece of bread and butter, when she was seized with vomiting, and immediately after she became unconscious and her whole body convulsed. But she soon recovered consciousness and was carried back to her bed, where I found her.

She lay there perfectly apathetic, the glare of the daylight seemed to hurt her, and the least noise to be painful to her acute sense of hearing. The room had to be darkened, and the attendants had to walk on tip-toe, to ease the little girl's suffering. At the same time she complained of pain in her head, and often held her little hands against it, though not permitting anybody else to touch her, the pain being evidently increased on pressure.

During the following week she remained much in the same condition. In daytime she often lay still for hours together, but was easily startled, especially by any sudden though ever so moderate noise, and could not bear the glare of the sun or gaslight. Whenever she was lifted, she had the sensation as of falling; the few times that she tried to walk a few steps, she reeled like a drunken person. Occasionally her physiognomy was peculiarly altered; her face appeared full of

grimaces, her facial muscles being evidently seized by a spasm. But her mother experienced the greatest anxiety at night, for Mary then, all at once, uttered a piercing scream, the so-called encephalic cry, and started up, as if she had been frightened by an ugly apparition. The vomiting persevered during the whole of this week; with rare exceptions, everything taken into the stomach was at once thrown up. There was no appetite; the tongue, though moist, was covered, contrary to most teachings, by a whitish fur; all diarrhœa had ceased, and constipation difficult to surmount, reigned instead.

The poor girl rarely passed a day during this period without her having one or two convulsions. They were always accompanied by chilly sensations, and often she seemed to suffer besides from internal spasms, which were indicated by her distorted features and by the same chills as those observed with the general convulsions. The spastic element occasionally showed itself only by the grinding of her teeth.

Towards the end of this week the picture somewhat changed, and assumed a still graver aspect. At times a slight increase of temperature had been noted before this, but the thermometer now recorded 101° F. every afternoon and about 101.2° every night. The pulse, somewhat increased in number of beats from the start, now began to be irregular. To the spasms, rigidity became added. The muscles of the nape of the neck and of the back at times contracted, and often remained stiff for several hours at a time; then relaxation set in, only to be again followed by the former rigidity. The abdominal muscles shared the same fate, but they permanently retracted and presented the well-known hollow appearance. Squinting also occurred; the eye-balls were occasionally turned upwards and the left pupil became decidedly dilated. I tried to make an ophthalmoscopic examination, but her sensitiveness to light was so great that I did not succeed, though I made repeated trials. I have never seen Trousseau's sign better expressed than was here the case. That the little girl became greatly emaciated will not surprise us, for she made but rarely an attempt at eating, and all the food that she did swallow was vomited again. Her skin assumed a sallow hue and was very dry.

In the afternoon of the tenth day—counting from the time when she came under my charge—the next stage of the disease was ushered in by a general convulsion, more violent than any she had yet suffered from. When the convulsion ceased, Mary did not at once regain consciousness, but fell into a comatose state, lasting for nearly twelve hours. When she came to she appeared very apathetic, and all former symptoms of irritation seemed to have vanished. She was no longer fretful, the eyes had lost their sensitiveness to light, noises no longer startled her, but her cries by night became still more frequent. The spastic and permanent contractures, however, not only remained, but were more expressed than had previously been the case. Her pupils henceforth remained decidedly uneven and the eyeballs diverged, while her face appeared greatly contorted, utterly changing the aspect of her once so lively features. Her head was buried deeply into the pillow, being thrust far back by the contraction of the muscles of the nape of the neck. The least attempt at bringing her head into a different position at once elicited a cry. Her left pupil was fixed, and did not at all react to light.

The twentieth day I noticed that her left arm was paralyzed. The pulse had become more rapid, but also more irregular, while her temperature no longer exceeded 99.3° F. The evening of the following day she was troubled with cough, for the first time since her illness. On examination, I found as the only morbid condition likely to explain this cough, hypostatic pulmonary congestion. Since her first attack of coma she had had one like it daily, her condition really being one alternating of coma and apathy. This state still continued, but the coma lasted by far the greater part of the day. There was no vomiting; the small amounts of milk, beef juice, and stimulants which she swallowed were retained. She seemed only to vegetate, the functions of circulation and of respiration almost being the only ones still carried on. Reflex irritations no longer elicited any response; but the convulsions, instead of ceasing, increased in frequency and degree.

The thirty-third day her pulse was 146; that day her respiration for the first time became noisy and irregular. There was nothing left of her by this time but the skeleton covered with a dried-up skin. Toward evening the next day her temperature suddenly commenced to fall; the thermometer, once applied in the mouth and once in the axilla, each time recorded 96.1° About five minutes later—the clock in the room had just struck six—the noisy respiration suddenly ceased; for the first time in several days Mary widely opened her eyes; her features appeared peaceful, and something of the light of the immortal spirit once more flickered across her emaciated countenance; with an intelligent look she turned toward her mother, who had so faithfully nursed her, and

parting her lips, she whispered, scarcely to be heard, "Water." When almost the next instant her mother held the glass to Mary's lips, first raising the patient's head, she discovered that the spirit had flown. I had closely watched the impressive scene; while applying the thermometer the last time the noisy respiration and the coma were continuing; a few minutes later, the clock struck the hour, and I at once noticed the ominous silence in the room, a silence which I can compare only to the passage of the death-angel, so beautifully described by the great German poet. Turning round to discover the cause of this sudden quietude, I observed the alteration mentioned in the patient's face, and found that the respiration was no longer noisy. Scarcely had the whispered word passed her lips, when her features relaxed, and the inexorable destroyer of all living beings ended the sufferings and the earthly existence of the child forever.

February 3, 1885, I was sent for by the wife of a patient of mine, R. F., whom I had attended for over a year for a left-sided empyema. This had apparently been cured; contraction of that side of the chest had ensued, but the patient still continued to cough, and did not gain in weight. Several months ago I had discovered dullness over the left and the right apex, and the temperature of the patient had since been 99.4° F. every night. When I was sent for the patient had been suffering for three or four days from constipation; an hour before I arrived he had taken his third dose of castor oil and immediately after been seized with vomiting and intense headache. The pain extended all over the head, but was not increased on pressure. I found the room dark, the patient explaining that the light hurt his eyes; at the same time he requested me to speak less loudly, as the noise "jarred his nerves." He was then sitting on a chair, and when I asked him to rise that I might examine him better, I noticed that his gait was unsteady, and he admitted feeling giddy when walking.

It was but with difficulty that I received these replies from him; he answered, but slowly, and most of the time I had to wake him out of his dreamy condition. This surprised me the more, as he had always been a great talker, and, in general, a very restless person. His wife said that he had been in his usual health up to within a few minutes after he had taken the last dose of castor oil, though she admitted his having been exceptionally irritable for the three days preceding, during which he had been constipated.

The disease in F. made rapid progress. The very next day he had to seek his bed, which he never left again. The symptoms, as they rapidly developed during the first week, were as follows: For hours he lay in a dreamy, half-sleepy state; then he was suddenly seized with delirium, during which he either sang all the while or talked all kinds of nonsense. He accompanied the singing by a continuous motion very similar to the one practiced by the leader of an orchestra, only more exaggerated. Then, again, he stared for half a day into vacant space, while picking in an absent-minded manner at the bed-clothing, or he remained for hours seemingly unconscious of himself and his surroundings. Several times at night he suddenly jumped out of bed, apparently frightened by some hallucination. He generally eat very little, though occasionally evincing a most voracious appetite, but whatever he swallowed was immediately vomited. The constipation persevered and yielded only every third day to drastic injections.

The ninth day he was suddenly seized with alternate divergence and convergence of his eyeballs, and the nape of his neck became stiff and remained permanently in that state. When I observed this rigidity, I examined his abdomen and found it flat and also somewhat retracted. His features at times were distorted, and the twelfth day this spastic condition attacked only the left side of his face, and ptosis of the left eyelid set in. That day I made an ophthalmoscopic examination. I discovered tubercles on the choroid and venous stasis of the papilla. His pulse about this time became very slow—between 56 and 60 per minute—and slightly irregular; the temperature every evening ascended to 100° F., being normal the rest of the day. His skin assumed a yellowish hue.

The thirteenth day F. appeared brooding. Towards noon he fell into a heavy sleep, lasting ten or more hours. The same occurred during the next two days. While thus asleep, he frequently moaned and touched his head. Then, again, he performed with his jaws a continuous chewing-like motion. The fifteenth day left facial palsy developed itself, and F. appeared to move his right arm and leg less than the extremities on the opposite side. The right side of his forehead and of the right temple were anæsthetic. Towards night his pulse became somewhat more rapid and more irregular. His spleen, which thus far had not seemed to be enlarged, decidedly augmented in size. During the night from the fifteenth to the sixteenth days F. fell into a deep

coma, and his respiration assumed the typical character of Cheyne-Stokes's. The sixteenth day at 11 a. m. he appeared to have a rigor; when I saw him at 11:30 a. m. his temperature was 109°, the pulse full and rapid—about 138—but very irregular, and at 1 p. m. death suddenly occurred, without his having recovered consciousness.

In both cases I made a post-mortem examination, but found nothing of special interest. In both instances the brain presented the usual and well-known picture of tubercular meningitis, and I refer, therefore, the reader to any work on pathology. I will mention only the facts, that on the surface of the convexity of the left anterior lobe at the seat of the first convolution, there was discovered in F.'s case some purulent matter, while in both cases intraventricular exudation was met with to a high degree. Whether this last fact explains the comatose condition, is difficult to say, cases having been published where coma occurred without increase of serum in the lateral ventricles. Whether there ever was a case in which a comatose state frequently occurred without well-developed extravasation in the ventricles, I cannot say. To my knowledge, whenever, in tubercular meningitis, coma seems to alternate with some other more or less apathetic condition, there is found after death an increase of serum in the ventricles.

As a rule, we may say that tubercular meningitis happens in individuals—children or adults—in whom (or in whose family) the tubercular taint exists. We often discover on inquiry, that some member of the patient's family has died of consumption, and in such a case the patient himself need not show any sign of tubercles previous to the meningeal disease. Or the patient gives evidence of scrofula, and here chronic enlarged glands, especially, are of diagnostic importance. Again, miliary tuberculosis, chronic pneumonia, pleurisy, etc., form the underlying malady, in the course of which the meningeal complication suddenly springs up.

While the usual course of the disease is well represented in the two cases above reported there are others where the picture of the malady is very different. Thus sudden paralysis occasionally begins the case, the palsy attacking either the vertical centre of speech, or one motor oculi, or one arm, or one side of the face, a. s. f. At times the complaint sets in with unconsciousness, or psychical symptoms appear in the foreground; in one case reported by Huguenin, the patient was seized with maniacal delirium. While some cases run a very rapid course, death occurring within the first week, others greatly resemble typhoid fever and may have a very protracted course. Though the pia mater is the original and main seat of the lesion, and though tubercular foci are never wanting at the base of the brain, there are cases where the fissure of Sylvius (its artery), the isle of Reil, or other parts, especially suffer. According to special localities, we may have peculiar phenomena. Still more difficult becomes the diagnosis if tubercular meningitis supervenes upon some chronic cerebral disease.

My experience, though not very considerable, has taught me to consider in the case of children the following points, when present, as sure indications of the existence of tubercular meningitis: When a child, in whose family there exists the tubercular taint, or which suffers from scrofulous swelling, suddenly, and without any apparent reason, becomes permanently changed in its temper, when, then, vomiting, constipation, and headache set in, to which are soon added irregular fever and an irregular pulse—provided all other diseased can be excluded—there is suspicion of the child being attacked by tubercular meningitis; a suspicion which becomes a certainty, if retraction of the abdomen, convulsions, and local spasms or local palsies—especially such of the third nerve—also occur.

In adults, if we cannot prove the existence of tubercles in the choroid, and thus at once recognize the disease, the diagnosis of tubercular meningitis becomes plausible, if intense headache and great apathy, or delirium, or coma, or all three, accompanied by ptosis or other local palsies of the eye or of one side of the face, and if one or more convulsions and rigidity of the muscles of the nape of the neck occur simultaneously or in rapid succession, and if while other diseases can be excluded, there is reason to assume the presence of a tubercular taint in the system. Neither Trousseau's well-known sign nor the encephalic cry is pathognomonic of acute hydrocephalus, and the irregular pulse, the palsy of the motor oculi or that of the face, and the convulsions are also met with in simple basilar meningitis, while the most violent delirium may be present in tubercular meningitis, though the convexity of the brain will then be found after death also to have been the seat of a purulent inflammation.

From these remarks, as well as, indeed, from the reports of the most experienced writers on this disease, the conclusion may, therefore, be drawn that there is not a single pathognomonic symptom characteristic of tubercular meningitis, but that it is the peculiar grouping together of a

series of symptoms happening under certain circumstances and in individuals either with a hidden tubercular taint, or with tuberculous lungs or glands, or suffering from miliary tuberculosis, or from scrofula, which authorizes us to diagnosticate hydrocephalus acutus.

A correct diagnosis, especially in children, is of vital importance, for lepto-meningitis infantum, whose symptoms greatly resemble the tubercular disease, is not necessarily a fatal malady, and other forms of meningitis also lead at times, at least, to a partial recovery. But tubercular meningitis, in my opinion, is invariably fatal. Though cases of apparent cure have been reported by trustworthy authors, a possibility of a mistake in diagnosis may so easily happen, that we cannot rely upon a few isolated cases as proofs. No post-mortem examination has yet been recorded, where the pia mater had given evidence of absorption of miliary tubercles, or of anything demonstrating the established cure of tubercular meningitis. If the cases of reported cure had ended as Huguenin's accidentally did,* the same result would probably have been always obtained.

Regarding treatment, we can speak only of palliative measures. The latest remedy in vogue —inunction of the head with a strong iodoform ointment—has not prevented the fatal end in the only case in which I tried it, nor influenced in the least the course of the disease. A blister to the epigastric region will often relieve the vomiting, and decided doses of the bromides lessen the frequency and the degree of the convulsions.

VOICE IN SINGERS.

ABSTRACT OF A PAPER READ BEFORE THE 39TH ANNUAL SESSION OF THE OHIO STATE MEDICAL SOCIETY, AT DAYTON, JUNE 5, 1885,

BY C. H. VON KLEIN, A. M., M. D.

The paper began with the exclamation, "Voice, beautiful voice, what is more precious than a delightful voice?" It has charmed kings and queens, princes and princesses, poets and peasants; it has been cultivated by thousands in every country and in every century. Vocal music has its origin with the beginning of mankind. But why does Italy produce such grand voices, not only among her own people, but even among those from other countries who go there to cultivate their voices? This success has been a mystery for ages. In the language of Gambetta, "Italy, beautiful Italy, where every man's voice is the voice of a mocking-bird." Two-thirds of her people can neither read nor write, yet her success becomes greater every year. The art of combining sounds agreeable to the ear has become a profound science.

Here followed a lengthy consideration of the anatomy and physiology of the vocal organs, closing with the assertion, "If all men were perfect all men would be singers."

Through the kindness and under the auspices of the late Dr. Bordini, of Rome, the author had made the examination of the throats of thirty-two Italians, thirteen of whom were professional singers. The Italians appear to have natural organs of voice for music. He found the throat very roomy, the tonsils almost level with the fauces, the uvula extending only $\frac{1}{8}$ of an inch from the soft palate, the posterior nares very large, the larynx thickly lined with a smooth mucous membrane, the trachea enormous. Another peculiarity was, the author found it very seldom necessary to use a tongue depressor. They seem to place their tongue down to the mylo-hyoid muscles, forming it into a concave shape. This accomplishment is necessary for a singer, and can be effected only by long and tedious training. Almost all nations appear to have cultivated their voices without regard to their timbre.

The Jewish people in very early times used vocal music in their religious ceremonies. The psalms of David and the songs of Solomon were executed with vocal music. The Egyptians, says Strapo, taught their youth vocal music by physicians. The mythology of Greece shows the ancient history of vocal music. The term music comes from Muses. There was a band of singers in the service of Osirisis. Roman music was cultivated by Servius Tullius 600 years before Christ. The Romans were accustomed to the best singing that the age afforded. Augustus, who did not at first esteem singing, late in life engaged a physician to regulate his voice. The Chinese, whose voices resemble that of a crow, cultivated vocal music from the time of Yaa and Chun, twenty-three centuries before Christ. Among modern nations, the cultivation of the voice has become one of the greatest arts. France established schools

* Huguenin reported a case of tubercular meningitis as cured. The symptoms really seemed to indicate beyond the shadow of a doubt the ailment as hydrocephalus acutus. Later the child died of pneumonia, with cheesy degeneration, and the post-mortem examination proved the apparent meningeal disease to have been simple serous effusion, "neither fresh miliary tubercles nor traces of absorbed tubercles were to be found either in the pia mater or elsewhere."—Huguenin's admirable article on "Affections of the Pia Mater," in Ziemssen's Cyclopædia, vol. xii.

of music in the 10th century. Germany has produced masters in vocal melody. Hungarians who came from Asiatic Europe in the 9th century, brought with them their vocal music. They were so fond of it that Rella III. sent an envoy to Paris in 1192 to be instructed in melody. In England, during the reign of Elizabeth, the talent of voice had been so cultivated that it has been surpassed in no country. The Swedes, Norwegians, Danes, Russians, Poles, Bohemians, Spaniards, and Potuguese are all music-loving people.

We now come to Italy, the nation of natural singers. Many theories as to the cause of Italy's numerous singers have been advanced, but few of them are tenable. The climate gets the credit of most of it. Let us then review and examine the climatic influence on voice. Mere latitude cannot determine climate. Paris lies north of Quebec, yet has a milder climate. The lowest temperature ever known in Italy was 2° below zero. In Ohio it reaches 20° below. It is true that the hygienic preservation of the voice depends on climate, but its development does not. Meliot states that in hot countries there are firmer voices than in cold ones. If a warm climate aids the development of the voice, why is it that the birds which possess the most diversified and complicated organs of voice, such as the nightingale, mocking-bird, lark, etc., are generally found in the cold climates, while on the contrary, the crow and parrot, coarse, noisy birds, inhabit hot or mild climates? It is claimed that the air of elevated plateaus has great influence on vocal organs, yet the Swiss and the inhabitants of the Alleghany and Rocky Mountains do not excel in song. Italy's superiority has been attributed to her sea breezes. The inhabitants of our Atlantic, Pacific, and Gulf States do not excel in song. One of the greatest follies is the theory advanced that the air of Italy is impregnated with iodine, bromine, and various saline principles, which is the cause of vocal improvement. Dr. Moffat, of Glasgow, claimed lately to have found the voice-making of Italy. He says on analysis it contains peroxide of hydrogen and free ammonia. He has an invention, the "ammoniaphone," which will destroy all deficiencies in voice culture Any one who will use one of these instruments will not be obliged to pursue a long course of study if he will daily take a few inhalations. This will entirely metamorphose the anatomy of the respiratory organs, changing the most uncultured and unmusical voice to one of surprising sweetness and melody. This is simply absurd delusion and deceit, ridiculous, mysterious, and false. The greatest singers of the world are not Italians, nor do they come from northern Europe. Parepa-Rosa came from old Scotland; Jenny Lind, Mad. Tarinia, Ostora, and Christine Nillson, from cold Sweden; Adelaide Phillipps and Elizabeth Billington, from England; Mad. Rudersdorf, from Russia; Mad. Theresa, from Hungaria; Henrietta Sontag and Paulina Lucca from Germany; La Blanche and Sophia Arnold, from France; Mad. Persiani, Louisa Kellogg, Emma Albani, and Miss Carey, from America; Adelaide Patti and her sister Caroline, though born in Spain, came to America when babes, and made their first appearance on the American stage at the age of nine years.

It is true that almost all those mentioned cultivated their voices in Italy, but their success cannot be due to Italian air. If inhalation of ammonia would have a tendency to improve the voice, all camel drivers, cow boys, and hostlers would be great singers. Some, as already remarked, have attributed the voice-making of Italy to iodine in the air. If true, why are not the sailor and fisherman, who constantly inhale marine vapors, great singers? One has said to me he attributed the success in music to the Italian language. Why, then, are not Gypsies great singers, who have the sweetest tone in their dialect? Another accredits the cause of excellence to the tyrannical discipline of the Italian schools and their peculiar mode of training and teaching. Those who go to Italy have made considerable progress in voice culture. They simply go there to refine it. The natives of that country, as a rule, confine themselves to music. Almost two-thirds of its inhabitants make a livelihood in this way. We must also consider the modification of the natural anatomical development of the lungs, trachea, and larynx, the scope of the throat, tongue, etc., which is peculiar to their race.

We have now considered the voice of Italy anatomically, physiologically, climatically, and gymnastically. If, however, we would consider the voice of nations, we would find that America has produced the greatest voices upon the face of the earth. The natural melody and sweetness of tone in American women has charmed the world, which adds to the enjoyment and fame of the American people.

—When Archbishop Whately was pestered by an aid-de-camp's conundrums, he thus disposed of him: "Do you know the difference between an aid-de-camp and a donkey?" "No," replied the aid-de-camp. "Neither do I," rejoined the archbishop.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY EDWARD T. BRUEN, M. D.,

Physician to the Hospital and Assistant Professor of Physical Diagnosis in the University of Pennsylvania.

Reported by William H. Morrison, M. D.

Hepatic Abscess, Phlebitis.

Gentlemen: The case which I present to you this morning is presumably one of hepatic abscess. Although the diagnosis is a little obscure, yet a study of the case itself will give us many interesting lessons respecting the symptomatology and etiology of abscess in this important viscus.

This old lady presented herself at the hospital some two weeks ago, with a lump under the margin of the ribs on the right side. It was about the size of a lemon, extended around the margin of the ribs to the right flank, and presented fluctuation. The introduction of the needle of a hypodermic syringe revealed the presence of pus.

The next step in the analysis of the case, was of course to review the possible causes of abscess in this region. In the first place the possibility of an abscess in the connective tissue of the back, an ordinary lumbar abscess, came up for consideration. This was speedily dismissed, because as the old woman is quite thin, it was readily determined that the external tissues were not affected, and that the abscess was a deep one.

We next studied the condition of the kidney by examining the urine. This was found to be nearly normal, so far, at least, as the secretion from the kidney was concerned. I shall, however, give you some reasons for believing that the bladder was not quite normal.

Examination of the lungs showed pulmonary resonance down to the tenth rib, posteriorly, the eighth rib in the axilliary region, and to the fifth rib anteriorly. The respiratory murmur was normal over the right lung, and there was no evidence of any pleuritic trouble. I refer to this because in the consideration of hepatic abscess, it is important to eliminate the possibility of empyema, since this is the most frequent cause of error in diagnosis. In addition to the points already referred to, I would call attention to the fact that in empyema of the right side, the liver itself is immovable, whereas if the abscess is in the liver, the organ will move to a certain extent during respiration, which movement will be revealed by careful percussion. This point is regarded by Frerichs as one of the most important next to the physical examination of the thorax.

Having excluded the possibility of empyema, having decided that the kidneys are normal, and having excluded the possibility of simple abscess in the connective tissue, we concluded that in all probability the abscess was in the liver. An incision was therefore made into the abscess, and about twelve ounces of pus was evacuated. The pus which escaped was tinged with green, evidently from the bile.

Having secured this evidence of deep-seated abscess, a probe was introduced, which passed upwards and buried itself for a distance of three inches in the hepatic substance.

With these facts in our mind, let us consider what further study of the case we can make with advantage. One of the most important conditions leading to a correct diagnosis is the existence of some cause for the abscess. Abscess of the liver is not infrequent in hot countries, but it is uncommon in this latitude. It is found that in hot countries it is nearly always connected with some form of disease of the intestinal canal, such as dysentery, or intestinal ulceration. The next most common condition is inflammation of the portal vein itself. As a result of inflammation, thrombus of the portal vein occurs, and from the area of thrombus, emboli are carried into the substance of the liver leading to the formation of abscess. It is, however, important to note that in this latitude abscess of the liver frequently occurs without this etiological relation. In six cases of hepatic abscess occurring in this hospital, in none of them was a lesion of the intestine found. It is therefore evident from these cases, as well as from the study of the literature of the subject, that in temperate climates hepatic abscess is not so frequently associated with intestinal affections as in the tropical zones. In the present instance, there is no symptom to lead us to suspect intestinal disease of any kind.

It has been assumed that a local injury may lead to hepatic abscess, and it is therefore important to carefully look for any evidence of a local origin of the inflammation. We can not attribute this abscess to such a cause.

Having excluded these causes of hepatic abscess, I have carefully considered the history of the patient to try and determine what condition of the system would predispose to the abscess. The patient's age (fifty years), would seem to place her beyond the period where abscess might develop from congestion of the liver. We find, on a close study of the case, a history of cystitis and uterine congestion. Six months ago, she was under treatment in the gynecological wards for some form of uterine disease which was associated with cystitis. There were no indications of pyelitis, for the urine was mixed with mucus. If there had been pyelitis, there would have probably been a large amount of pus, associated with a certain amount of pain in the back. It is, however, difficult to establish exactly the differential diagnosis between pyelitis and cystitis.

I would associate this condition of hepatic abscess with the cystitis and uterine disease. There has probably been inflammation of some of the veins around the uterus and the bladder, and the formation of thrombi in these veins, with the transference of emboli or irritating material to the liver and the development of secondary abscess. In support of this view we have the well-known pathological fact that next the disease of the intestinal canal, abscess of the liver is most frequently connected with some form of inflammation of the veins of the lower extremities, or of the pelvis. Bearing in mind this point in reference to the etiology, let me call attention to the symptoms. One of the important features of this case has been the absence of any symptoms indicating an internal collection of pus. Under these circumstances, you are supposed to have hectic

fever and sweats, the peculiarity of this sweating being that it is intermittent. Sweating sometimes occurs from prostration of the system from exhausting diseases, such as typhoid fever; this sweating is apt to be constant. I have recently had this fact forcibly brought before me by a case in which the differential diagnosis as to the presence or absence of pus hung largely upon this symptom.

As regards the temperature, in some cases of hepatic abscess the temperature fluctuates in the way usual in hectic fever, but not to the same extent. There seems to be a rule about the variation of the temperature, and this is that it changes with the functional activity of the organ, that is to say, during the periods while the patient is taking food. Simple as that observation may seem to be, it has an important bearing upon some cases of abscess which are apyretic. Abscess of the liver occurs quite frequently without there being a single symptom of elevation of temperature. I recall one case occurring in this hospital. The patient was supposed to have some form of jaundice. He walked down stairs, smoked his pipe, and suddenly dropped dead from rupture of an abscess into the peritoneal cavity. Cases are frequently reported in which the temperature does not go above one hundred, or even above ninety-nine. How do we explain this? You will recall that the physiological temperature of the liver is about 106°, and that the temperature of the liver is elevated during the process of digestion perhaps to 107°, 108°, or 109°. On the other hand, if the liver is inactive, the temperature of the organ will decrease. It has been experimentally demonstrated that if the products of liver digestion are rapidly absorbed into the system, the general temperature will rise, while on the other hand, it has been demonstrated that if an animal is starved, the general temperature will fall, as will also the hepatic temperature. Applying these facts to the condition before us, we can understand that although there has been the formation of an abscess in the liver, which would naturally tend to increase the temperature of the whole body, yet the patient being feeble and anæmic, with poor digestion and diminished functional activity of the liver, the temperature has not been markedly increased.

Let me now refer to the character of the pus. It was formerly stated by many authorities, that pus drawn from the liver was chocolate color. This is due to admixture of blood with the pus, and is dependent upon some alteration of the blood vessel structure of the gland. In this case, as in the majority, the pus presented the ordinary characteristics. It was streaked with bile, which was due to the opening of some of the biliary channels.

Abscess of the liver is far more common in the right lobe than in the left, and the anterior portion of the right lobe is the most common situation. Although hepatic abscess may open anywhere, it usually opens below the ribs. The next most frequent mode of opening is through the diaphragm into the pleural cavity, and thence through the lung and the bronchial tubes. Next to these the opening may occur into the colon or directly into the peritoneum. These facts show the importance of tapping abscess of the liver early. I was surprised, I may say horrified, on reading the statement in Quain's Encyclopœdia of Medicine, that abscess of the liver should not be tapped, because it will finally work to the surface and adhesions will form between the abdominal wall and the liver, and the abscess will open spontaneously, or may be opened more readily than if exploratory tapping is attempted. I am quite sure that the general experience in connection with abscess of the liver is that it should be tapped as soon as there is reason to expect the existence of pus, since perforation into the peritoneum is not unlikely. An exploratory needle may be introduced into the tissue of the liver, and the organ explored in various directions without injury. Too much stress I think has been laid on the necessity of having adhesions between the liver and the adjacent tissues before the opening is made. The aspirating needle can be introduced and the pus withdrawn without wounding the peritoneum. I can hardly think of an abscess of the liver so situated that it could not be opened in some of the positions in which the liver is superficial.

After the abscess has been opened and drained, what is the outlook for the patient? It is reasonably favorable in an individual whose nutrition is good. Abscess of the liver often has no capsule, its walls consisting of hepatic substance. Cicatrization of a very large abscess of the liver is unusual on this account, but in an individual whose general nutrition is good it is reasonable to hope for cicatrization of hepatic abscess after drainage, in the same way that we have healing of any other abscess. Still, the course of the majority of cases is towards a gradual exhaustion of the patient from suppuration. I fear that this case is one in which an extremely favorable prognosis can not be entertained; at the same time she has been doing well since the abscess was opened, and her temperature has not been above 100°.

Before dismissing this case, let me refer to one other matter. Should we inject this abscess? I think there is no reason why an abscess of this kind should not be treated on general principles, but I think that the solution should be weaker than those used in the pleural cavity. Disinfectant solutions are only to be used when the pus has an unhealthy odor. Injections for the cure of abscess are used for two purposes, first, to stimulate granulations and thus favor healing, for the purpose of disinfection, thus rendering the pus as little septic as possible. The pus from this abscess has been pretty healthy, and has had no offensive odor, and we therefore have not used injections.

We have examined the pus for the presence of hepatic tissue. Dr. Fenwick has maintained that it was possible to find liver cells in the pus from hepatic abscess. You well know that the liver cells are very granular, even in a physiological condition, and it is difficult to recognize the hepatic cells when broken down and mixed with the products of suppuration. I have been unable to obtain any evidence of hepatic cells in the pus from this abscess, but our examinations will be repeated. The majority of observers have not confirmed the view of Fenwick.

Phlebitis.

I shall next show you two cases of a condition

which is not extremely frequent. I allude to phlebitis. Both patients are suffering with phlebitis of the left lower extremity. The first patient was admitted to the hospital seven weeks ago with apex pneumonia. It is important to note that he was a drinking subject. Eleven days after admission he developed tenderness along the femoral vein, which rapidly extended to the calf. This tenderness was associated with extreme pain and a renewal of the fever.

The second case is that of a man who gives a very imperfect history of himself. The general features of the case are however similar to those of the first case. He was seized a short time ago with pain running down the leg to the calf in the course of the femoral vein. This was soon associated with a certain amount of swelling, some of which you see to-day. In this case the pain has not been so intense, but is more a feeling of numbness and soreness.

What is the cause of this condition? I think that an important feature in the diagnosis of phlebitis is to determine whether it is a local trouble or whether it is an evidence of general septic inflammation. There is no trouble in saying that in the first patient the whole trouble was a local inflammation of this series of veins. I suppose that the etiology of the case was this: the man had been a drinking subject, and was suffering with pneumonia. Both of these conditions tended to interfere with the circulation by depressing the heart and general circulation, and the pneumonia assisted in producing a reduction in the force of the venous circulation; and secondarily we suppose that there was a thrombus formed in consequence of the slowing of the blood-current. It is a curious fact that this disease nearly always occurs on the left side of the body. It is extremely common in any condition in which the circulation is much enfeebled—in typhoid fever, dysentery, and cholera. The last case of thrombus which I have seen was in a case of severe cholera morbus. The femoral artery was closed by a clot which I believe was due to slowing of the blood-current by the drawing off of the serum by the bowels. I do not mean you to infer that the clot blocks up the whole vein. Fibrine accumulates along the wall of the vessel, and tends to block up the vein, and following this there is inflammation of the vein. I told you on a previous occasion that if the venous circulation is partly obstructed, the lymphatics, if free, are capable of removing the fluid, and there has to be considerable venous obstruction, if the lymphatic channels are free, before œdema will occur. In some cases of phlebitis all the symptoms of pain, tenderness, and swelling in the course of the vein, are present without much œdema. This is because the lymphatics are free. In our second case, although the lymphatics have not been involved, the venous obstruction has been so marked that the lymphatics could not take up the exudation. Next to the determination whether the disease is a local one or not is the determination whether or not the lymphatics have been involved. Most recent clinicians and pathologists have decided that lymphatic involvement converts a case of phlebitis into a case of phlegmasia alba dolens. There is much confusion as to what is meant by a phlegmasia alba dolens. The clearest idea to carry in the mind is that it consists of phlebitis with lymphatic involvement. It may occur in connection with typhoid fever or other exhausting disease, but is most frequent in the puerperal state.

Suppose that the inflammation of the vein is not a local trouble, as in these cases, how may it be caused? The other cause is the transference of a septic embolus to a pocket of the vein. Suppose you have dysentery, there is ulceration of the bowel, and phlebitis occurs, what is its probable cause? In an inflamed vein in the neighborhood of the ulcer, a thrombus has formed, which has in turn given off an embolus, which in a large majority of cases is septic. This passes into a vein of the extremity, creates irritation, and produces a septic phlebitis. In the same way, in the puerperal states, there is the formation of a certain number of clots in the uterine sinuses. If these are associated with some septic condition, there may then be a thrombus which may give rise to emboli of a septic character. In puerperal phlebitis the inflammation may be non-septic, and the main point is to determine whether or not the process is septic. The two forms of inflammation give rise to the same local symptoms, and the diagnosis must be based upon the general symptoms of pyæmia or septicæmia; that is to say, hectic fever with a daily rise and fall of temperature and intermittent sweats. In the case alluded to a few minutes ago, a case of puerperal phlebitis, the important point which could not be settled for several days was whether the phlebitis was septic in character or simply a local trouble. The case was somewhat confusing, because there was profuse sweating all the time, and a temperature curve from 100 in the morning to 104 in the evening. That was not the temperature curve of septicæmia, which usually ranges from 99 to 103, and is associated with intermittent sweating, flushes, and rigors.

I hope that I have made clear the importance of differentiating between local and septic phlebitis. If it is a septic condition, we must look out for secondary consequences, such as abscess in various organs and general septicæmia. In local phlebitis, you can give a prognosis of recovery in a comparatively brief period.

Let me say one or two words in reference to treatment of local phlebitis as we have it in these cases. The best treatment is, I think, the conservative. In these cases the limb has been enveloped in cotton, and the patient has been kept perfectly quiet. It is advisable not to do too much in attempting to arrest the inflammation by blisters, iodine, mercury, and so on. If the pain is severe, hot fomentations, as of laudanum and water, may be employed, and in very severe cases lead-water and laudanum may be used; but lead-water is objectionable because it hardens the skin and prevents a careful determination of the amount of induration due to the trouble in the veins. Internally, opium is to be used freely to relieve the pain. Morphia may be used hypodermically, but it is to be borne in mind that in septic cases, hypodermic injections are liable to produce localized abscesses. In such cases it is better to use opium by the mouth or rectum. We also use tincture of the chloride of iron and quinine. Quinine has a tendency to arrest inflam-

matory processes in general, and it certainly has a positive effect in septic inflammation.

If the phlebitis is septic, is there anything else to be done? I really think that it does not make much difference. At present, some favor the use of small doses of carbolic acid. Personally, I think that you cannot antagonize a septic poison in the blood by such means. The plan, I think, should be to maintain the crasis of the blood and the constitution of the tissues. If the character of the cells can be kept up to a certain point, the septic materials cannot attack them. We have an illustration of this in phthisis. We know how often phthisis is arrested. I grant that occasionally treatment will do this, but more commonly the cure is spontaneous, and is because the process of repair exceeds the process of wasting. The patient is, perhaps, removed to a climate where he can have exercise, he takes plenty of food, and the improvement in nutrition will give such a vital capacity in the cell that it will cease to break down. So in septicæmia, if you can increase the vitality, you can prevent the spread of the poison. Beyond this, I think that nothing can be done.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, May 22, 1884.

The Vice-President, Dr. Amy S. Barton, in the chair.

The first paper was

Removal of a Lymphoma from the Neck—Recovery.

By Dr. Susan P. Stackhouse.

The patient was a woman 40 years of age. Sixteen years ago she first noticed a small tumor, just below the left ear; there was no inconvenience caused by it except the projection of the earring. On seeking medical advice, she was told there was no danger attending the growth so long as it remained undisturbed. It increased in size very gradually, and was attended with no pain nor tenderness. The patient entered the Woman's Hospital of Philadelphia, and was operated upon by Dr. W. W. Keen, October 17, 1884. The tumor then extended from the ear to an inch below the cricoid cartilage, and was 2½ inches in width; from its size it began to interfere with deglutition and respiration. The skin was not involved, but the veins were enlarged, and two pulsating vessels could be felt to enter the tumor. The growth was movable, to a certain extent, firm and inelastic.

Operation.—After the patient was etherized, an incision 4 inches long was made, care being taken to avoid the external jugular vein, which crossed the growth. The hemorrhage, which was quite profuse, was arrested by hæmostatic forceps and ligatures; it being necessary to ligate *eighteen* vessels. On account of the vascular nature of the growth, and its loose connections with surrounding structures, the adhesions were broken up with the grooved director. The tumor was intimately connected with the internal jugular vein for nearly 3 inches, and very careful dissection was required in order to preserve the integrity of that vessel. Nearly all the deep structures of the neck were exposed on the removal of the tumor. The wound was closed by wire sutures, after the introduction of a drainage-tube and a bundle of horse-hairs. The operation required one hour, and the patient became very much exhausted, but reacted very quickly after a hypodermic injection of brandy.

The wound was dressed on the following day, on account of there being considerable oozing of blood; the tube was then removed, the horse-hairs being left. After this the patient did very well; temperature never reached 100°; the only difficulty being some trouble in deglutition for three or four days. On the eighth day, when the dressings were removed, scarcely soiled, the wound was found closed, with the exception of one small point. The patient was discharged from the hospital two weeks later, in good health, the cicatrix being only a slight disfigurement.

Dr. Stackhouse also reported "A Case of Complete Retroversion of the Uterus from Distension of the Bladder."

July 22, 1884, while serving as interne at the Woman's Hospital of Philadelphia, I was called to a woman who was said to be dying. The patient was 35 years old. Temperature normal, pulse 100, feeble and irregular, respirations gasping and rapid, face anxious, eyes injected. She did not complain of any pain, only a constant desire to urinate; said that she had passed urine repeatedly, and pressure upon the abdomen caused some flow of urine. The abdomen was greatly distended, the patient saying that the enlargement had existed for ten days, and had come on suddenly without any previous illness; did not think she was pregnant. On examination of the abdomen, its enlargement was found to be due to an oval, elastic tumor, extending from the symphysis pubis to within two inches of the ensiform appendix. It was regular in outline, and in no way resembled a pregnant uterus. On examination per vaginam, I found that the tumor had no connection with the uterus; that organ was completely retroverted, the fundus being only a short distance from the vulvar orifice, and the cervix in front of the symphysis pubis. The uterus was somewhat enlarged, and perfectly immovable. The patient insisted that she was not pregnant, and said that four months ago her abdomen became enlarged suddenly, she was unable to urinate, and the physician, on passing the catheter, drew off a large quantity of urine, and the condition was relieved. I therefore passed a rubber male catheter, No. 16 French, and drew off fifty ounces of very pale, clear urine; it was neutral in reaction, sp. gr. 100.2, containing a small quantity of pus, but no albumen.

The relief was very great; the respirations were no longer gasping, and the face lost its anxious expression. A soft French catheter, male, was introduced into the bladder, and kept in place by perineal bands of adhesive plaster. The paralysis of the bladder was complete, and lasted for a week. It was found impossible to restore the uterus to its normal position by manipulation, so the patient was told to place herself in the knee-chest position for five minutes at a time frequently during the day. At the end of ten days

the patient was perfectly well, urinated without difficulty, and the uterus was restored to its normal position.

Dr. Louise S. Blum then read the report of

A Peculiar Case of Death from Asphyxia, Caused by a Plate of Artificial Teeth Impacted in the Trachea.

The literature on the subject of foreign bodies in the air-passages is exceedingly rich in rare and peculiar cases of extreme interest. Almost every physician has been called upon, at least *once* in the course of his practice, to remove some article from the air-passages of a child who has made the mouth a common receptacle in place of the pocket. In such cases there have been found and removed pins, needles, marbles, fish-hooks, rings, buttons, button-moulds, pebbles, sticks, pens, slate-pencils, ears of rye, wheat, or barley, fruit stones and seeds, and numerous other articles. Neither, it seems, is this reprehensible practice confined to children alone, for a number of the above-mentioned articles, as well as some others, have been removed in the cases of men and women. Buckley, for instance, removed a copper umbrella tip from the larynx of a woman; and in two other cases on record, a puff dartand a hard rubber tube were similarly removed. Instances of pieces of the various kinds of food entering the air-passages during deglutition, are of such frequent occurrence that that they receive no mention. Of far more importance and interest to the medical profession is tne fact that tracheotomy tubes and corroded pieces of the same, hypodermic needles, and various surgical instruments, or portions thereof broken off during operation, also unsecured corks for keeping the jaws apart, leeches carelessly applied, sponges, etc., have all, at various times, been found in the respiratory tract. Scarcely less interesting is it to read that matters vomited during anæsthesia or unconsciousness during apoplexy or epileptic attacks, as also regurgitated chyme, curdled milk, worms from the alimentary tract, pus from tonsillar, post-pharyngeal or epiglottic abscesses; necrosed nasal, palatal, and cranial bones, and laryngeal cartilages, have all at various times acted as foreign bodies in the air-passages of man. Even a lymphatic bronchial gland, one inch in length, has been known to have caused death by becoming impacted in the rima glottidis during a violent fit of coughing. A still more remarkable case is that recorded by Ruehle in "Kehlkopfkrankheiten," in which the epiglottis of a man was drawn into the upper orifice of the larynx during deglutition, where it became firmly impacted, and acting as a foreign body caused death. During operations upon the teeth and mouth, one or more teeth, or crushed fragments of the same, have frequently fallen into the windpipe. More rarely a number of artificial teeth, connected by a metal, have become dislodged during sleep, and were drawn into the larynx or trachea by the attempts made at respiration. This accident has also occurred during deglutition, although in that case they are usually swallowed with the bolus of food, and enter the stomach. Still more rarely has this accident occurred where a number of artificial teeth were attached to a plate. The only case of the kind on record, to my knowledge, is that reported by Mr. Henry G. Croly, of Dublin, cited by Prof. Gross, in which instance seven artificial teeth, set in gutta percha, were arrested at the juncture of the larynx and trachea. The case which forms the subject of this paper is a parallel one, but is far more peculiar than the majority of such cases are likely to be, from the fact that the accident occurred in the course of an acute disease, and was not suspected until after the death of the patient.

On February 18, 1883, I was asked to call upon Caroline H., æt. 25, widow. Examined the patient carefully. Temperature 104° F., pulse 128.

On the following day I called twice, taking the morning and evening temperature, which, together with the previous history of the case, confirmed my diagnosis of malarial fever of the remittent type.

February 21. Temperature 103° F., pulse 115.

February 22. Temperature 102° F., pulse 110; within an hour after my visit I was hastily recalled to the patient, the messenger saying that she was dying of hemorrhage. I found the patient, her face livid and convulsed, held down by *four* people. As I reached the bedside she gave a few gasps expired, and before anything could be done for her relief. With the last gasp of the dying woman, and the consequent dropping of the lower jaw, the mother noticed the loss of the teeth, and called my attention to the fact. Thinking that they had dropped out of the patient's mouth during her struggles, I advised a thorough search of the floor.

In the evening I called again to ascertain all possible details of the last hour of the patient's life, and found that immediately after I left she had taken her medicine and composed herself to sleep. Suddenly the nurse, who was looking out of the window, was startled by a peculiar, barking sound. On turning round and seeing the patient with eyes rolled up and face fearfully convulsed, she became frightened and ran down stairs for help. By the time the others reached her side she was violently convulsed, her face livid, and blood flowing from her mouth. This, as I had readily ascertained, was from the bitten tongue, and was small in quantity, although it gave rise, in the minds of the family, to the idea of hemorrhage. The convulsive movements, though violent, were of short duration, and had about ceased as I entered the house. Upon inquiring for the teeth, I learned that, although the room had been swept, they had not been found; after hearing this fact, together with the details of the case, I felt convinced that the teeth had become dislodged during sleep, and had entered the air-passages and thus caused death. A post-mortem examination was made the next day, and revealed the following: The heart and lungs, otherwise normal, presented the usual signs of death from asphyxia. The liver was congested and softened. The spleen was enlarged and very much softened, thus verifying the diagnosis of malarial fever. All the other organs were found in a normal condition. This much having been ascertained, search was made for the missing teeth, which were found in the trachea, about *two* inches below the larynx. The plate was of the usual size, of vulcanite, and had *four* teeth attached to it; it was so firmly wedged that force, little short of violence, was required to remove it. In the vigorous efforts made

to dislodge the plate, one of the teeth, which seems to have been imbedded in the walls of the larynx, was broken off and left behind.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, May 14, 1885. The President, Dr. Shakespeare, in the chair.

Fracture of the Pelvis; Rupture of the Bladder; Fracture of the Forearm.

Presented by Dr. De F. Willard.

H. C., æt. 23, was admitted to the Presbyterian Hospital, 3, 27, 1885, having fallen a few hours previously under a backing locomotive, which, when stopped, held him firmly fixed beneath the ash-pan. In starting the engine to extricate him, he was again rolled by this ash-pan, which was not more than fifteen inches above the cross-ties. On admission, no lacerations of the skin were visible, but the contusions about the pelvis were well marked. The pubic, lower abdominal, and upper femoral regions were extremely ecchymosed. The right arm and left iliac regions were emphysematous and painful. There were no evidences of urinary infiltration in the perineum or scrotum, although the latter was blackened by ecchymosis. Crepitus was marked at every movement of the pelvis; the left trochanteric region and buttock were much flatter than upon the right side, and pressure increased the deformity so much that it seemed probable that the head of the femur could be pressed into the pelvis through the acetabulum. This was not so, as was subsequently proven, but was due to the great mobility of the anterior pelvic fragment. At least two lines of fracture could be discovered at the iliac crest, and one at the pelvis. Both bones of the right forearm were also broken in the lower third, and there were many contusions of the trunk. A catheter easily introduced into the bladder secured many blood-clots, and about two ounces of urine. Shock was not excessive, and although restless during the night, only small doses of morphia were necessary. On the following day the mind was perfectly clear. Vomiting soon occurred, but unaccompanied by severe abdominal pain. Diligent search was made for extravasated urine, as only half an ounce was found in the bladder; but the only suspicious territory was to be found in the left iliac region, and here the ecchymosis and contusion was so great that no positive conclusion could be reached. Temperature 102.1° F., pulse 150. Death occurred on the third day from peritonitis. Post-mortem.—Complete separation of the symphysis pubis was found, the left fragment with its sharp end having made an opening in the anterior wall of the bladder about one-eighth of an inch in diameter, through which aperture a small quantity of urine—say two or three drachms—had found its way into the connective tissue, and lay just behind the symphysis. Another fracture extended from behind the anterior superior spinous process downwards just behind the acetabulum, through the ischium; another ran from the centre of the crest into the obturator foramen, and the sacrum was torn from the ileum at its synchondrosis. There was blood in the peritoneal cavity, but no pus, and but little lymph. The examination showed that the small collection of urine could not have been reached by puncture, and that the small amount of urine obtained by catheterization was due to suppression, and not to its extravasation. The kidneys were much congested. The fractures were undoubtedly produced by the lateral pressure in rolling, which reduced the patient's transverse diameter from seventeen to fifteen inches.

Dr. Wharton said that there were several points of interest, and especially with regard to the urinary symptoms. Did he understand Dr. Willard to say that the catheter had been passed and no urine withdrawn?

Dr. Willard replied, several times, evacuating only a few drachms each time.

Dr. O'Hara would ask the reporter as to the condition of the kidneys. As total suppression of the kidney secretion was evident, it would cast some light upon it to know the pathological expression of shock in the actual condition of the kidneys. Shock is very often a general and unmeaning term, but if there was an actual diseased condition, whether recent or old, it would be well to record it, in reference to the details of the case. Belfield in "Diseases of the Urinary and Male Sexual Organs," had, to his mind, negatived many cases of shock, and proved that they depend on "negative pressure," or "hyperæmia ex vacu." Dr. Belfield seemed to the speaker to have clearly made out the matter in reference to the kidney on anatomical and pathological grounds.

Dr. Willard answered that the kidneys were very much congested.

Dr. Nancrede differed *in toto* from Dr. O'Hara, in his explanation of the suppression of urine in this case. It was well known, experimentally as well as by post-mortem evidence, that in "shock" an enormous accumulation of blood in certain instances took place in the abdominal viscera, due to paralysis of the abdominal vaso-motor system of nerves. Pure congestion, if sufficiently marked, was competent to produce suppression even in a healthy kidney, AND THIS SUPPRESSION TOOK PLACE BEFORE ANY CATHETERIZATION WAS ATTEMPTED, as was distinctly stated by Dr. Willard. In Dr. Willard's cases Dr. Belfield's "negative pressure" theory was a mechanical impossibility, as it required a previous *retention* of urine either in a bladder with healthy walls, or in one whose parietes were rigid, and could not therefore collapse. Neither of these conditions obtained in the case under discussion, and the kidneys had practically ceased to secrete before any catheter was even near the patient for introduction, since he was admitted to the hospital *some hours* after the accident, when only "about two ounces of bloody urine" was evacuated. Even with regard to the cases where the mechanical conditions were favorable for "hyperæmia ex vacu," he doubted if this was always the correct explanation. The theory was not new, and he thought was carried far beyond its legitimate limits by Dr. Belfield, with whose work, he would assure Dr. O'Hara, he was peculiarly familiar.

(*To be continued.*)

EDITORIAL DEPARTMENT.

PERISCOPE.

Traumatic Epilepsy Cured by the Use of Trephine.

Dr. J. R. Weist thus writes in the *American Practitioner*, May, 1885:

The very valuable paper of Dr. W. T. Briggs, of Nashville, Tenn., on the "Surgical Treatment of Epilepsy," read at the meeting of the American Surgical Association in 1884, and published in volume ii. of the Transactions of the Association, having brought the question of the propriety of trephining for the cure of epilepsy again prominently before the profession, the following brief report of a successful case may be of some interest:

Frank Mitchell, nineteen years old, was struck at the upper and outer margin of the right frontal eminence by a number one shot, January 12, 1878. He was brought to me soon after the injury. The small opening in the scalp was enlarged and the flattened shot found slightly imbedded in the bone. The shot was removed, some headache was complained of for a few days, but the wound soon healed. About two weeks after the injury, while riding in a wagon, he had a severe epileptic seizure; soon after this the wound opened, and did not entirely close for about five months. During this period frequent headaches were complained of, and several small scales of bone were removed. About a year after the accident a second epileptic seizure occurred, and attacks followed, at first every two or three weeks, gradually increasing in frequency during four years. Then for two years, and up to the time of operation, they occurred two or three times per week, generally of severe character. He was still subject to frequent headaches, worse on the right side. The epileptic seizures were preceded by increased pain in the head, and a tendency to turn the head to the right. No special impairment of the mental functions was observed. The slightly depressed cicatrix, about half an inch in diameter, was tender. On April 6, 1885, assisted by a number of medical gentlemen, a triangular flap was raised over the seat of injury, and a button of bone three-fourths of an inch in diameter removed by the trephine. The cicatricial tissue of the scalp was found adherent to and to pass through a small opening in the bone, which was very thin, and attached to the dura mater. After the button was removed, it was found that the centre-pin of the trephine, which had been protruded but very slightly, had not been placed on bone, but on cicatricial tissue, and it is probable that the point had penetrated the dura mater. A drainage tube was placed in the wound, the flap held in place by two or three sutures, and a light compress applied. The next morning the patient was doing well, but it was observed that the dura mater was raised through the opening above the level of the bone and pulsated strongly. These phenomena had disappeared on the next day, when pus escaped freely from beneath the flap. On the third day the pulse beat rapidly, pain in the right side of head was complained of, and slight symptoms of paralysis appeared on the right side of the face and in left arm and leg. These unfavorable symptoms increased. The pulse and respiration became slow, with complete motor and partial sensory paralysis on the left side, with marked comatose symptoms. Discharges involuntary. All the signs of cerebral abscess were present, but operative procedures were delayed because of its apparent location. The motor centres of the arm and leg are about two inches posterior to the opening in the skull, and they were evidently involved.

Finally, thirteen days after the operation, Dr. Bond, who had charge of the case during my absence from the city, freely divided the dura mater and brain through the opening already made in the skull; considerable pus was discharged, and in five hours motion appeared in left leg and arm. Pus continued to discharge for several days, then serum for a few days, when the flow ceased, and the wound was allowed to close. In a few days all unfavorable symptoms save a slight headache disappeared. The patient was discharged from the hospital, and his condition still remains good. He has had no epileptic seizure since the operation; and, having been free of an attack longer than at any time during six years, there is reasonable ground for the hope that a cure of the epilepsy has been effected. He will be kept for some time on the use of sodium bromide.

By giving attention to the facts herein recited regarding this case future errors may be avoided. Probably the center-pin of the trephine wounded the dura mater; this was followed by an effusion of blood beneath it, shown by the pulsating tumor, and inflammation and suppuration. By using the trephine through an opening in a disk of wood or leather, the use of the center-pin would not have been necessary. Perfect drainage was not provided for, and another preventable cause of inflammation of the membrane and brain allowed to be present. It would, perhaps, have been better practice to have entirely removed a portion of the scalp corresponding to the opening in the skull. In this way perfect drainage would have been effected, and as the dura mater would have been under direct observation, it would have been incised as soon as made prominent by the blood or pus beneath.

Thus through our mistakes may we acquire wisdom.

Multiple Saroma of the Skin: Treatment by Hypodermic Injections of Fowler's Solution; Recovery.

Dr. Frederick C. Shattuck thus writes in the *Boston M. and S. Jour.*, June 25:

July 26, 1883, K. B., thirty-one years old, was admitted into the Massachusetts General Hospital. Her health had usually been good, and

she had worked at dressmaking up to the time of admission. Seven months before that date she began to suffer from pain along the lower jaw, and soon after noticed swelling behind the angles of that bone. About two months later nodules appeared in the skin over her right shoulder, then on her right arm, next on the left, next on the abdominal wall. She thinks that the appearance of the nodules was preceded by local tenderness, and followed by discoloration. About three weeks ago she noticed that her face was fuller than normal, and she began to suffer from pain in the cardiac region. She was somewhat short of breath on exertion, and reported that she had lost decidedly in strength, though not in flesh. The bodily functions were in fairly good order. The pulse was 120, regular, rather weak.

On examination, it was noted that the patient was pale, with some œdema of the eyelids and face, preponderating on the right side. Scattered throughout the skin of the upper extremities and the body as far as the umbilicus were hundreds of nodules, mostly about the size of a pea. Over the inner aspect of the arms the nodules were discrete, not raised above the surface, slightly tender on pressure; the skin could be wrinkled over them, and was not discolored. On the outer hand, over the shoulders, outer aspect of the arms, breasts, upper abdomen, and back—though in the latter situation to a less degree—the nodules were so thickly sown as to form large masses or plates, very hard and but very slightly tender; the skin covering this could not be pinched up or wrinkled, and was markedly erythematous, with slight scaly desquamation of the epidermis. In the legs a very few nodules could be felt, and there was no erythema. The glands at the angles of the jaw were enlarged, but those of axilla and groin were apparently normal. Thorough examination failed to reveal any material modification of the great viscera. I made the diagnosis of multiple sarcoma of the skin, and soon after Drs. White, Wigglesworth, and Tilden were kind enough to accede to my request to see the patient, concurring in the diagnosis.

General tonic treatment was prescribed at first, but Köbner's brilliant success in a similar case with the subcutaneous use of Fowler's solution induced me to adopt his plan toward the end of August. An injection of four minims, diluted with an equal quantity of water, was given once daily, deep in the thigh. September 15th Dr. Tarbell resumed charge of the wards, and soon after increased the injection to six minims. The general health of the patient improved, a few fresh nodules appeared, but the old ones disappeared in much larger numbers, and November 3d she was discharged from the hospital, in order that she might work a portion of her time. She came daily to the hospital, however, for her injection until she was furnished with a syringe and taught its use, and treatment was persisted in steadily till the middle of March, when I opened an abscess in the thigh, the only one which formed during the whole time. A few nodules still remained, but the masses which filled the skin over the breasts, abdomen, and outer side of the upper arm had entirely disappeared, and during the past year she has been under observation from time to time without any treatment whatever, and has worked steadily at her trade. I have seen her within a few days, and she remains perfectly well to all appearance.

Early in 1884 I showed her at a meeting of the Medical Improvement Society, but have purposely allowed a year to elapse before reporting the case, in order that there might be no doubt as to the result.

Cases of multiple sarcoma of the skin are rare, and the authorities on diseases of the skin have little to say on the subject. All agree that the prognosis is absolutely unfavorable, and the course generally a rapid one. Köbner's is the only case recorded up to date, so far as I am aware, in which recovery took place. I now regret that one of the tumors was not excised and examined microscopically, as was done by Köbner. The patient was extremely averse to the operation and preferred to wait, promising that she would make no objection if she got worse. To this delay I consented, having very little faith that treatment would prove of any avail. Still, even without the evidence of the microscope, I think there can be no doubt as to the diagnosis. The experts were unanimous, and I had previously seen two other cases very similar, except that they ended fatally. Was the cure really attributable to arsenic? If so, would the drug have acted as well administered in the usual way by the stomach? These are questions which can only be answered by extended experience. It is interesting to state that ten days after the arsenic was stopped the urine was examined for its presence by Professor Wood with a negative result.

False Reduction of Hernia.

The *London Med. Record* tells us that Dr. P. Berger gives, in two papers which have appeared in the *Revue de Chirurgie*, some illustrative cases and remarks upon this interesting subject.

Commencing with the account of a case of Arnaud's which occurred in 1730, he gives in detail eleven cases which have been published, and one which came under his own notice. Of these twelve, it appears that six were inguinal and six crural herniæ, and in an appendix are added three cases of an allied nature, communicated by Professor Azam, of Bordeaux. Of these, only two (Arnaud's and Berger's) recovered, and Berger's died after ten days, though the reduction was effected.

On anatomical examination, he finds the hernial sac and the proper course of the hernia empty: in the deepest part of the latter is the bend of the strangulated intestine, folded back into the cellular tissue of the iliac fossa in the case of an inguinal hernia; behind the pubes, in the cellular tissue of the pelvis by the side of the bladder, in the case of a crural hernia. It is still pressed upon by the neck of the sac, which may have been divided or not, and it makes its way into the subperitoneal connective tissue, through the opening made by the deep incision of the operation for the relief of the stricture. Sometimes there may be a peculiar anatomical arrangement, such as an exposed testicle, or a fibrous cord like that of the umbilical artery, or adhesions between the intestine and the neck of the sac, which explains the difficulty the surgeon may have had to encounter during the operation, and be a reason why the

intestine passes along the course which manipulation and instrumental interference have prepared.

In almost all the necropsies it was found that the cause of strangulation, or at least the obstacle to reduction, had not been removed by operation. Moreover, it is evident that the surgeon often has himself prepared the "false route" into which he has forced the intestine; and Dr. Berger urges that the injudicious force used in attempting reduction is the principal factor in this complex action, the result of which is the substitution of an internal for an external strangulation.

He discusses the symptoms which accompany or follow this accident. Of course, the ultimate absence of relief to the ordinary symptoms of obstruction makes this obvious; but it is important to notice any features by which the failure can be detected early, and he quotes freely from the experience of Pelletan and others, that the feeling of fullness and firmness of the intestine ought to indicate a state in which no danger exists of the accident occurring when this condition persists after a supposed division of the cause of strangulation. Besides this, the finger introduced into the course of the hernia does not pass freely into the abdominal cavity. The intestine can be distinguished, and may be found not to be freely movable in the peritoneum, but fixed and presenting itself to the finger always in the same position, and in the same character. The author says truly that, the longer the discovery is postponed, the more difficult and obscure the case and its treatment become.

The practical conclusions arrived at may be summarized thus:

1. The surgeon should bear in mind the possibility of the accident and its usual origin from incomplete division of the stricture, or from division of tissues which are not the real cause of strangulation, and from pressure during taxis having been too long or too forcibly attempted.

2. The persistence of symptoms of strangulation points to a false reduction. The special symptoms and signs have been indicated, but two points are specially worth notice. *a*. When the operation has been done several hours, or even a day or two, without the symptoms of strangulation ceasing, can the surgeon distinguish such a false reduction from those cases of pseudo-strangulation due to paralysis of the gut after intense or long-continued pressure? The answer is difficult. False reduction is not followed by even temporary relief of any kind; moreover, the pain is localized, more or less, and the swelling can be made out with careful manipulation. Then, on searching by the finger in the wound, the intestine is found distended and fixed in position, and the seat of strangulation is not relieved. *b*. When we are clearly in the presence of a false reduction, can we be sure that it is due to displacement under the peritoneum rather than to any other cause? The other cause indicated is adhesion of the gut to the sac. This can only be answered by the careful exploration of the wound.

3. When the existence of the false reduction is made certain, it must be put right, and to do this it is necessary to draw down the gut from its false position to learn the nature of the obstacle, and then to reduce the hernia after proper division of the stricture.

Septicæmia from Human Bite: Recovery.

Dr. M. Whiting thus writes in the *Peoria Med. Monthly*, May, 1885:

In view of the attention that has been recently given to the poison of human saliva, under certain conditions, I will report a case which occurred in my practice a year ago.

D. W. German, aged twenty-two, married, sent for me in January, 1884. On visiting him, I gained the following history: Two weeks previously, while engaged in expelling an unwelcome visitor to his marital couch, he received a bite over the second phalanx of the middle finger of the right hand. The bite upon the dorsum was of insignificant importance and soon healed, but that upon the palmar surface remained an open sore until the date of my visit.

On examination, I found an ugly, foul sore over the second and third phalanges of the finger, the edges were thick and dark, while from the wound exuded a thin and very offensive purulent discharge. On probing, I found the bone carious and exposed. The whole finger was tensely swollen and had been extremely painful. The hand was of a dark-red color and œdematous to the wrist, while the arm was somewhat swollen, slightly œdematous and painful to the shoulder. Red lines marked the internal aspect of the forearm. Axillary glands enlarged and tender upon pressure.

General Condition.—Tongue furred, bowels constipated, no appetite, high fever, temperature 103, pulse 120, weak and thready. Several hours before my visit he had had a severe chill, which was followed by a decided increase of fever. Having lost sleep for several nights previous on account of the pain in the finger and hand, his appearance was haggard and anxious. At the time of my visit he was literally bathed in a copious perspiration, which had come on an hour or two before.

Cleansing the wound as well as possible with a carbolic acid solution and ordering flaxseed poultices, I prescribed four grains quinia sulph. every four hours, also a laxative, and a mixture containing ten drops of muriated tincture of iron, with stimulants. This treatment was continued for three days without any perceptible change in the patient's condition. During this time he had frequent chills, followed by an increased temperature, and a large blister appeared over the first phalanx, extending back to the metacarpo phalangeal articulation of the finger, from under which offensive pus could be pressed into the wound. At this time I requested Dr. T. M. McIlvaine to visit the patient and advise concerning the amputation of the finger, which I had urged from the beginning of my attendance. My consultant advised delay in the operation, giving as his reasons therefor, the extremely bad condition of the patient, and apprehension that the exposure of a large fresh surface would only give a freer entrance for the septic poison into his system. He advised the continuance of the quinine, substituting syr. ferri iodidi in twenty-drop doses for the tincture of iron, and the application of charcoal and yeast poultices to the finger. This treatment was vigorously pursued for the ensuing ten days, within which time I removed the second phalanx of the finger.

At the end of three weeks the patient's condition began to improve, the sweats grew less, fever abated, appetite returned, and he was able to leave his bed. The finger, however, did not improve much, except that the discharge was lessened and not so offensive. The patient now agreed to the removal of the offensive member, and accordingly, with the assistance of Dr. McIlvaine, I removed the finger and head of the corresponding metacarpal bone; the tissues making the flap were wonderfully thickened, and so soft that I did not believe a suture would hold; still, to my surprise and gratification, the wound healed very quickly, and in a few days was entirely closed. From that time on he made a rapid recovery, and in a few weeks more resumed his work.

Treatment of Spinal Irritation.

Dr. George W. Ryan read a paper on this subject before the Ohio State Medical Society, June 4, 1885. The essayist stated that he proposed to consider this condition more particularly in its relationship to joint troubles and the cases that come especially under the care of the orthopedic surgeon. Of the various names this affection had been given, he thought the term spinal irritation the best, as it was expressive and comprehensive enough whatever the pathology might be. Its influence in arthropathies had been pointed out by Gibney, Shaffer, and other American writers in recent years. He did not believe it essentially a hysterical condition, but rather that hysteria was the result of it. It was often mistaken for Potts' disease of the early stage. Its influence in deformities and apparent disease of the joints was the widest field in its secondary troubles. The essayist stated that he had seen cases which had worn apparatus for months which were promptly relieved by treatment directed to the cause of the deformity; others in which this condition had not been recognized had suffered when prompt relief could have been given had it been intelligently applied. He believed it would be a sound rule to examine the spine in every case of joint trouble where the disease was not unmistakable. The "Brodie" joint often resembled the joint of chronic disease, but was generally characterized by the rapidity of its onset, and generally the absence of the characteristic symptoms of bone lesion, but often extreme tenderness. Deformity nearly always accompanied it. He had not been able, in many cases, to find the "tender points" spoken of by some writers. The hip, the knee and ankle, were the joints generally affected by this condition. Club-foot was occasionally found with a neurotic cause. The essayist read the report of two cases, one in which the spinal trouble followed acute articular rheumatism. The patient had been confined to her bed and invalid-chair for more than two years; was unable to walk but a few steps. The case was so far relieved in six weeks that she was enabled to get about very well, and has continued to improve. The other was of five or six years' standing, in about the same condition as the first, and was relieved in about the same time. The treatment in both cases had been the Paquelin cautery, faradism and spinal support. The essayist believed that the Paquelin was better suited to cases that required treatment extending over several weeks, but he had seen prompt results from the large fly-blister in the more acute cases. Faradism was of great service where there had been loss of muscular power. Massage had been used to a limited extent in the cases. No medicine except tonics were employed. The speaker thought the value of the spinal support had been underestimated; he had found it of considerable value, used solely as an adjunct. Theoretically and practically, he believed it indicated in most cases, and the patient finds it gives relief to the burning sensation experienced after exertion.

Empyema Treated by Daily Aspirations.

Dr. Dan Millikin, of Hamilton, read a paper on the above subject before the Ohio State Medical Society, June 4, 1885, wherein he approached the subject only in the line of a theorist. He wished only to throw out a hint of a new line of treatment, and sought rather to be instructed than to instruct. He reported a case of pneumonia, which, while resolving, became pleuro-pneumonia, and the left pleural cavity became filled with pus. His distress being very great, the doctor made all haste to aspirate, obtaining a great quantity of horribly offensive pus. The treatment consisted of a daily withdrawal of pus until the patient complained of tightness, oppression, or pain. He then entered his protest against further aspiration, and a quantity of some antiseptic fluid was thrown into the cavity of the chest. Fluid was withdrawn and injected with each sitting until it returned clear and limpid; at the end of the sitting it was so thoroughly withdrawn as to leave the patient in some slight distress. The recovery was rapid and complete notwithstanding that the patient had been reduced by a long illness before the development of the empyema. He reported a second case. Pleura filled with pus in very tuberculous patient. Daily aspirations healed completely the pleural trouble, though he was at the same time dying of tuberculosis.

The doctor thought there was an advantage in a small opening in the chest; other things being equal, a small hole is better than a large one, and one better than two. That it is better for the pus to flow only when the doctor is present, and the clothing to be clean in the intervals. He thought it best to have the orifice slanting or valvular. He recommended care to keep the drainage-tubes from slipping into the cavity. By means of the aspirator the lung was subjected to a daily stretching, such as it could not have had by any other means convenient, and not at all with a free opening of the chest. By leaving a slight vacuum after each sitting, he occasioned a gradual expansion of the lungs and contraction of the chest, and caused the mediastinal border to make a convexity towards the affected side of the chest, and give the sound lung more room. Gravity cannot coax pus out of a pocket; the aspirator can.

Dr. P. S. Connor, of Cincinnati, said he had seen aspiration succeed, and he had seen it fail. He had seen patients run down hill after repeated aspirations and recover when a free aspiration was made.

Dr. Joseph Ransohoff, of Cincinnati, has dis-

continued aspirating for empyema. All the cases upon which he has operated have died when tuberculosis was present. He mentioned a case of his where a drainage-tube was lost in the chest for fifteen days with no special harm. He thinks early free incision will save most cases.

Dr. Kinzman, of Columbus, spoke in favor of free incision for empyema. He operated as soon as aware that it was purulent. He is not fearful about air getting into the pleural cavity.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a recent reprint Dr. J. H. Musser, of Philadelphia, describes three cases of idiopathic anæmia. He concludes with a judicious hint as to the prevalence of the disease:

It had been thought because in parts of Switzerland the inhabitants were so frequently affected with idiopathic anæmia, it was an endemic disease. It will be seen that three places in this country give nearly all the cases, and yet we believe, for reasons entirely apart from endemic influences. Thus fifteen of the cases were observed in Philadelphia, thirteen in Canada (Montreal and Toronto), eight in Boston, and the remainder in separate localities. This is to us curious, and yet readily explained. In each locality the great attention paid to blood diseases was apparently more influential in recognizing the disease.

——Dr. W. W. Keen, of this city, has set forth the advantage which vivisection has been to medical science in a lecture entitled, "Our Recent Debts to Vivisection." He concludes with the just observation:

The sentiments of our own profession, so constantly and so conspicuously humane, are always against inflicting pain; but if in yielding to sentiment we actually increase disease, and pain, and death, both among animals and men, our aversion to present pain is both unwise and actually cruel.

——A description of a case of infectious ulcerative endocarditis and of one of acute pericarditis has been sent us by the authors, Dr. John H. Musser and Dr. George A. Pierson, of this city. They are instructive cases.

——The bromide of ethyl appears to promise well as an anæsthetic in labor. In a reprint before us, by Dr. E. E. Montgomery, of this city, the writer reports 112 cases, in which it was used without any fatality for mothers and with but three deaths in children, none of which could be attributed to its action.

——"The External Therapeutics and the Dietetics of Pulmonary Consumption," is the title of a suggestive paper by Dr. Thomas J. Mays, of this city, reprinted in neat form. The same writer treats of "The Physiological Action of Cocaine and of its Analogue Brucine." Both reprints can be had of Mr. George T. Davis, publisher, Detroit, Mich.

BOOK NOTICES.

A Text-Book of Medical Physics for the Use of Students and Practitioners of Medicine. By John C. Draper, M. D., LL. D., etc., with 377 illustrations. Cloth, 8vo., pp. 733. Philadelphia, Lea Bros. & Co., 1885.

It is rather hard on the already overladen student of medicine to add another to the "auxillary sciences" on which he is required to pass an examination. But the relations of physics to all the exacter sciences are now so numerous and so indispensable for their comprehension that it is not easy to see how it can be avoided. The author is not correct in supposing—as he intimates in his preface—that the subject is a new one in this country. But certainly we have no text-book which treats it as fully as the excellent one he has prepared. It begins with a statement of the properties of matter; then proceeds to its distinct forms as solid, liquid, gaseous, and radiant matter. Energy is treated of as potential and kinetic, and motion as translatory. After these, the special departments of physics are explained, acoustics, optics, heat, electricity, and magnetism, closing with a section on electro-biology. The applications of all these to physiology and medicine are kept constantly in view.

The text is amply illustrated, and the many difficult points of the subject are brought forward with remarkable clearness and ability.

Manual of the Antiseptic Treatment of Wounds. By W. Watson Cheyne, M. B., F. R. C. S., etc. 8vo., cloth. Pp. 146. New York, J. H. Vail & Co.

Those who would like to acquaint themselves, without spending too much time, with the doctrines of antiseptic surgery, will find this little volume just what they require. The author, who is a well-known authority on the subject, begins with the modes of repair in wounds, describes the species of bacteria and the means of their destruction, enumerates the materials employed in aseptic surgery, gives an example of an operation of the aseptic character, catalogues the special dressings in use, speaks of their modifications for country practice and in war, and concludes with a list of the chief antiseptics and the most approved methods of their employment. The illustrations are numerous, and are very neatly printed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

HEADACHE.

It is such a common thing to hear a person say, "*I have a headache,*" and it is as equally common to hear the reply, "*It will soon pass off,*" and we so constantly find such recommendations for its relief as a cup of tea, or a nap, or "vinegar and brown paper," and we so seldom inquire into the *cause*, unless the headache is so continuously persistent or some other prominent symptoms imperiously force our attention to a close examination, that we reproduce the following remarks from the *Lancet* as well worthy of careful consideration:

"Headache, although so common an affection, possesses a peculiar interest on account of the tantalizing obscurity in which its cause is often shadowed. Depending upon one or two main physiological principles connected with the passage of nervous impulses and the calibre of cerebral blood-vessels, it yet arises in response to so many different stimuli, that, practically, the branches of its original stem of structure, its distributive variations, are perplexingly numerous. Among the forms but recently described and named, though probably as old as art, is the 'academy headache.' Critics and doctors have vied with one another in trying to translate this term according to the rules of medical logic, but have not, so far, been able to agree as to its meaning. In venturing to put forward our own opinion on the subject, we think it best to notice the different circumstances which tend to produce in the frequenter of galleries that general sense of fatigue which is often the precursor of pain, and then to note the special stimulus which brings out of this chaos the formed and local ache. It should be noted that all do not suffer from this form of headache; while of those who do, some are less and some more affected. Fatigue may be the limit of annoyance with a certain class. They are heavy-limbed and heavy-headed, languid, but no more. The forces at work upon them are the warmth of the crowded room, the summer sunshine pouring through the skylights, the listless rotation or circulation, rather than walking, through the rooms, and the weariness of much-divided attention. Being robust and used to go about upon their feet, they soon lose the feeling of languor after its causes cease to act; and if their eyesight be equally healthy, they suffer no strain in these organs. There are other persons, of weaker organization or more sedentary habits, in whom pain quickly follows fatigue, and it is felt, for certain reasons, chiefly in the head. Among these

reasons we must note the fact that in the standing position the blood, driven by a languid heart, reaches the head with greater difficulty than when recumbent. Anæmia is one cause of headache. Anæmia, too, is associated with changes of arterial calibre which constitute the usual cause of megrim. Under these conditions, also, the giddy malaise of a loitering gait is painfully perceptible. Concentrated attention increases the uneasy sensation. The frequently constrained position of the head has its influence. It would be strange, moreover, if ocular movements had no share in the production of this complex indisposition. Let any one converge his eyeballs to an acute angle, as in squinting, or let him direct a sidelong glance of extreme obliquity, and a single effort will convince him of the pain of such muscular effort. No doubt this is the pain of muscular tension, acute and so far abnormal; but it is also possible to induce a similar pain from the strain of too frequent muscular action within the normal limits of accommodation to distance or other movements of the eye. Ocular pains of this kind are felt as an aching about the middle and back of the head. The scrutiny of paintings or engravings, from the many points of interest which have to be noted, requires a considerably greater exercise of the muscles of the eyeball than is called for in ordinary life. In this fact, established, as we have already stated, on a basis of fatigue and general muscular and nervous strain, we have probably the usual exciting cause of the form of headache we have been discussing.

DISEASE AS AFFECTED BY THE CLEARING AND CULTIVATION OF LAND.

Among the papers presented to the Ohio State Sanitary Association at its meeting last February, was one which we have read with much satisfaction, as it has appeared in full in the published Proceedings of the meeting. The subject is "Climatic Changes in Ohio, from the Destruction of the Forests and the Drainage of the Land, and their Effects on the Health of the People." The author, Dr. R. Harvey Reed, of Mansfield, has taken pains to collect from old physicians in the State, and from local sources, a mass of information not heretofore accessible, and his results are of importance not merely for the medical history of his own State, but for that of our whole country, which has but recently emerged from the forest wherever we go.

He traces the progressive removal of the primitive forests, the upheaval and drainage of the soil, and correlated to them, the modifications in the types of prevalent diseases. His general conclusions are so interesting that we give them:

1. From the destruction of the forests we have more wind, more humidity, and more rainfall (as shown by the Signal Service records), more dust, more sudden dashes of rain, resulting in more sudden changes from one extreme to the other, both as relates to temperature and moisture.

2. From the immense amount of artificial drainage, and the improvement of natural watercourses, there is a much more rapid transmission of water from the periphery to the great trunks and basins.

3. These two causes combined, act—1st, in removing the surplus surface-water supply more rapidly; 2d, by the decidedly increased evaporation: they together rob the natural regulators, and lessen the common supply of springs and wells, while the latter require deeper average penetration (as is shown in the records of well-driving firms), and the former, which once were strong, have partially or totally failed.

4. These changes have been followed with a decrease of all forms of malarial diseases, and an increase of typhoid fever, together with a very decided increase of all forms of catarrh, and their common sequelæ—deafness and chronic pulmonary troubles.

Finally the author is of the opinion, in addition to all these, that the increase of wind and dust is a decided factor in the propagation and spread of all forms of contagious and zymotic diseases, and furnishes a rational explanation for the frequent occurrence of the so-called sporadic cases of contagious diseases.

From some similar observations which we collected about twenty years ago in the State of Illinois, which, as our readers are aware, is largely a prairie state, and where the changes could not have come from the denudation of the soil, there had been a similar alteration of type in disease since the first generation after the general settlement of the country. The forms of malignant "bilious fever" with which the old physicians had to combat are now scarcely met with; malaria, though frequent, is unquestionably less severe; typhoid fever has increased; and spinal meningitis is decidedly more abundant. The cli-

mate has been modified much, as in Ohio, the cause apparently being the more rapid surface drainage.

It is highly desirable that these investigations be carried out while there are still living in most of our states physicians whose experiences carry them back to the epoch of the settlement of their localities, or nearly so.

Notes and Comments.

Plantar Neuralgia.

We cannot read too much about neuralgia, for there is probably no disease, that is not fatal in its character, that is so obstinate and so resisting in treatment; hence we reproduce the following case which Dr. C. W. Suckling reports in the *London Med. Times*, June 13:

H. E., a single woman, aged 38, employed as a domestic servant, was admitted into the hospital, April 9, 1885, complaining of pain in the soles of the feet, and inability to walk or stand on account of the pain. Both her parents had suffered from rheumatism, and two of her brothers have had rheumatic fever.

The patient had had jaundice twice, otherwise she had enjoyed good health, but was not robust. About four years ago, she had pains in both her feet, similar to the present illness, but soon recovered. Three weeks before admission she got her feet damp, and the next day they were very painful. There were shooting pains confined to the soles of the feet near the heel. The pain was much aggravated by walking or standing, and much relieved by lying down.

When examined on admission, there was considerable hyperæsthesia of the soles of both feet and tenderness. The hyperæsthetic area was close to the heel, and measured an inch and a half in length, and one inch in width on each foot. When the feet are allowed to hang down the painful areas become red and the veins stand out, and free perspiration follows. The same phenomena occurred after walking a few yards. There was a tender spot behind the internal malleolus and another over the heel. There was no special tenderness, no pain in the back, or any sign of disease of the spinal cord or its membranes. There was no pain in the joints, nor any heart murmur. The urine was normal.

The patient was kept in bed, and a blister applied behind the internal malleolus of each foot. Simple rest in bed relieved the pains, but she always suffered from them at night. Repeated blistering finally caused complete cessation of the pains.

At the time of reporting (May 9) hanging the feet out of bed does not cause them to become red or to perspire, and walking does not cause pain. For the time, at any rate, the patient is well.

This disease was first described by Weir Mitchell, and is said to be rare in women.

On the 20th of May the patient left the infirmary perfectly well.

On the 25th the patient, after having tramped about and been much exposed, was re-admitted, the pains having returned, but in a less degree than when first admitted.

A Case of Idiopathic Tetanus.

These cases are sufficiently rare to warrant reproduction; hence, we note the case which Dr. O. N. Royle reports in the *Lancet*, June 13:

He was sent for at two o'clock on the morning of March 11th last to see the patient (a woman). The messenger, upon inquiry, informed him that she had been feeling ill for the last ten days, with spasms and slight pains in the stomach, and that her bowels had been unrelieved for more than a week. Looking at the constipation as cause and effect—the night, moreover, a stormy one, and the house some distance from his residence—he did not consider the nature of the attack one of sufficient urgency to pay a visit at that early hour, so sent her by the bearer a brisk purge of croton oil, with directions to foment the body well until he saw her. Calling at eight o'clock the same morning, the bowels, he found, had freely acted, but the pain and spasm associated therewith had much increased. He then for the first time recognized the nature of her case. The last day in February, it seems, this poor woman had become greatly alarmed at seeing the hand of a child placed on a machine for cutting turnips in motion, although with no injury to the child further than a slight graze of one finger. It was a clear case of idiopathic tetanus from nervous shock. The poor husband was in great grief and distress about his wife, whom he succeeded in calming by the assurance that she would soon be better; nevertheless, every day for more than a week after first seeing her the symptoms increased in severity. Trismus and opisthotonos at one time were well marked, the latter coming on after an interval of some hours, and lasting from five to ten minutes, resisting apparently all treatment employed, first with opium in two-grain doses every three hours

for three consecutive days, then with chloral in half-drachm doses every four hours for a like period, with very little improvement, and subsequently with one grain of morphia injected hypodermically every night with two of Indian hemp, repeated at short intervals during the day—the symptoms after this treatment gradually disappearing on the second day until her recovery, just three weeks after receiving the shock. The case he thinks of some interest and worthy of record; first, from the great impression made on the nervous system from so slight a cause; again, no marked symptom of the disease showing itself until the eleventh day after the fright, resisting at first all treatment; and lastly, succumbing to Indian hemp and morphia injections, a line of treatment he should commence with most certainly if ever called upon to treat a similar case.

Periostitis Following Typhoid Fever.

The specific relation (if there is any) between typhoid fever and periostitis, is an interesting field for observation. We have already noticed several cases that have been reported, and now in the hope of causing further notice of this phenomenon we record the following case which Dr. Thomas Preston Gostling publishes in the *Brit. Med. Jour.*, June 6:

"The patient, a young woman, aged 17, had a moderately severe attack of fever, with a relapse occurring on the twenty-first day of illness, and before the first attack had subsided. The spots were very numerous, and involved the extremities, being present below both elbows and on the inner part of the thighs. There was constipation throughout; and in the relapse she complained of deafness and pain in the left ear, without any discharge. The pain lasted two days, the deafness four days.

"On April 2 (fortieth day of disease), and after the temperature had been normal for six days, the patient complained of pain over the centre of the right tibia, on its inner surface, and the temperature rose to 99.2°. There were very slight redness, some swelling, and also well-marked tenderness. Extract of belladonna, mixed with an equal quantity of glycerine, was smeared on the part, and hot fomentations were applied, which relieved the pain slightly for a time, although, on April 3, the swelling had increased in size. Redness now extended over an area of about four square inches. Fluctuation could not be obtained, and the attempt to do so caused intense pain.

"On April 6, the temperature had reached 99.6°; the pain had increased; the tenderness had become excessive; and the swelling had become larger, now measuring 4 inches long by 3½ inches wide. The pain was much worse at night, and kept the patient awake.

"An enlarged painful gland was noticed in the right popliteal space on April 9, and on the following day there was distinct fluctuation over the centre of the swelling. It was opened by a small longitudinal incision, and half a drachm of pus escaped. The temperature came down to normal the next day, and remained so until the discharge of the patient. The pain was at once relieved by the operation.

"A careful examination did not show any bare bone. Fomentations were continued until April 14, when, the wound having commenced to granulate, it was dressed with red wash, and it had entirely healed by April 21. The swelling had also entirely vanished."

A Series of Cases of Diphtheria.

The following series reported in the *Brit. Med. Jour.*, by Dr. T. H. Sawtell will furnish food for thought:

Between April 20 and 30, diphtheria attacked all the children living in a house in Hornsey Rise, members of two families. The ages were three and three-fourths years, four and one-half years, three and one-fourth years, two and three-fourths years, eighteen months, and eight months respectively, six in all.

The first patient was moribund when his parents called me in. Chloroform and emetics failing, I did tracheotomy. For twenty hours he breathed well, but died four hours later. The necropsy revealed collapse of both lungs, with non-adherent membrane throughout the trachea and bronchi, the subjacent mucous membrane smooth, slimy, neither tumid nor congested. On the tonsils, the usual diphtheritic appearances were present. He had been ill for nearly four days.

In the second case, the air-passages proper seemed to escape, but the membrane rapidly invested the eyelids, nostrils, mouth, and fauces. All these surfaces bled freely. Hard œdema, with enormous swelling, occupied the whole neck, finally reaching the chest-wall. There was no marked dyspnœa. On the seventh day, stasis, and hemorrhages occurred in the limbs, and the child died quite suddenly from clotting of blood in the heart or great vessels. There was no post-mortem examination.

The treatment, adopted also in the other four cases, modified as circumstances required, was, brandy very freely, tincture of perchloride of iron

in five-minim doses every four hours, frequent emetics, with a diet of milk and egg. While the throat was actively inflamed, I used antimony to produce vomiting, following it with abundant brandy.

The child aged three and one-fourth years, although exhibiting very acute symptoms, rapidly recovered after three days.

Cases four, five, and six were very severe, all having malignant symptoms, with epistaxis, etc. After much trouble, however, they escaped. In my judgment, tracheotomy was contra-indicated in all the cases except the first. The interest of these notes lies in the fact that four out of five malignant cases, two of them infants, were treated successfully with abundant brandy, frequent emetics (at first antimonial), and iron, the membrane on the tonsils and pharynx being undisturbed; in fact, the throat was not touched.

Intra-Pulmonary Injections.

The treatment of phthisis has at all times been unsatisfactory; cases often progressing steadily downwards in spite of our most active therapeutics. Dr. W. C. Phillips, in the *New York Med. Jour.*, June 20, 1885, records two cases of intra-pulmonary injections, one in advanced phthisis and the other with a large superficial excavation.

Solutions of permanganate of potash, iodine, and carbolic acid have been used by other experimenters with invariably good results. The doctor used Lugol's solution diluted with five times its quantity of water, using an ordinary hypodermic syringe.

The injection causes but little pain, and is to be performed at full held inspiration, as it is then easier to keep the lung in repose. He suggests that the needle be graduated in inches and fractions thereof, thus enabling one to be more accurate.

Both of his cases were followed by good results; in one the improvement was marked.

The case of Pepper's, referred to in the article, has been seen a number of times by the writer in the Philadelphia Hospital. Her disease has undoubtedly been held in check by the injections used by Pepper ten years ago.

The doctor offers as suggestions, first, could not the injection be given with impunity much oftener than has been recommended by Pepper and Robinson? Second, is not the severe paroxysm of coughing caused by the injection being thrown directly into a bronchus?

In regard to the first, he says his patient received five injections in eight days, and the result has been not in the least disastrous. In regard to proposition second, each time that the patient had a paroxysm of coughing she at the same time mentioned that she observed the acrid iodine taste in her mouth; at times when she did not cough she complained of no taste in the mouth; hence, the conclusion is obvious that the cough is caused by the irritating effect of the fluid upon the membrane of some part of the bronchial tract.

Hysteria, with Attacks of Tetany, Induced by Pressure on the Ovary.

E. L., a woman aged 27, was admitted into the Queen's Hospital, February 23d, 1885, suffering from paraplegia. She was markedly hysterical and had the characteristic "facies hysterica." While in the hospital she suffered from globus, clavus, dyspnœa and flushings of the face. At times also she had photophobia.

There was marked ovarian hyperæsthesia, and firm pressure over either ovary at once produced flushing of the face, a painful sense of fulness in the throat, and choking, quickly followed by rigidity of hands and feet, the hands assuming the characteristic posture observed in tetany. The legs and feet were strongly extended, the big toes showing a tendency to be flexed. Trismus was also brought about at the same time. The rigidity quickly passed off after discontinuance of the pressure. On one occasion catalepsy was present, the limbs maintaining any position in which they were placed for a considerable time.

The treatment consisted in isolation, blistering over the situation of the ovaries, and Faradization. The patient when discharged could walk well, and had lost the ovarian tenderness; no symptoms were produced by pressure.

The above case, which Dr. C. W. Suckling reports in the *London Med. Times*, June 13, is very instructive and possesses much practical interest, in so far as it will serve to remind us that in very many of those mysterious and illy-defined hysterical conditions so often noted in women, the ovaries are at fault; it reminds us that we should look to and direct our treatment to these little organs. Pressure over the ovaries will often serve to unravel hitherto mysterious cases.

Osphresiology.

The *Med. News*, June 20th, tells us that Dr. Monin, Secretary of the French Society of Hygiene, has recently written a monograph upon the odors of the human body. The Society of Medicine of Paris has given him its triennial prize for this

work. The subjects successively treated in it are the odor of the skin and its appendages, the odor of the breath, of expectorations, of vomited matters, and of eructations, of feces and intestinal gases, of the urine, of the female genital organs, and of suppuration and gangrene.

Various pathological conditions are indicated by the odor of the skin, or of its perspiration, and by that of the breath. For example, the skin has an ammoniacal odor in cholera, and in dysentery the perspiration has the odor of the anal dejections; in hysteria the hair has the odor of ozone. In diabetes the breath has a sourish odor; if this odor be slight, it is due to aldehyde, but, when more marked, it is due to acetonæmia; a garlic odor of the breath in infants indicates intestinal worms, and upon this indication alone anthelmintics may be given.

Of course, the detection of faint odors will depend upon the olfactory power of the individual, and one may be able to perceive distinctly that which another fails to recognize, for doubtless there are just as great variations in the sense concerned as have been shown to exist in the sense of hearing, or in that of seeing. It is probable that science, which has done such marvels in making the unseen seen, so vastly increasing the size of an object of research, will one day find means to make odors more distinct, and thus assist professional investigation.

Heroic, or Poisonous Doses.

At a recent meeting of the Société de Thérapeutique M. Huchard brought forward to the notice of his colleagues several examples of accidents succeeding the administration of iodide of potassium in large doses. Besides the iodism usually observed, such as swelling of the eyelids, œdema of the face, and even purpura iodic, other symptoms of a graver character have been observed by him in two cases. The first, that of a man who took forty grains of the iodide and a drachm of the bromide for an aneurism, very violent dyspnœa followed. The second, a syphilitic, was attacked with such severe suffocation after having been given a certain quantity of the iodide, that tracheotomy had to be performed to save his life. M. Lereboullet said that when he was house-surgeon at a hospital in Strasburg he saw given for syphilis as much as *nine drachms of iodide of potassium a day*. Rarely evil results followed this large dose, and he thought that idiosyncrasy in many persons would account for the accidents referred to. In affections of the aorta and atheroma he has given it in small doses (five or six grains) with the best result, but it should be continued for a long while. M. Huchard said that he gave the salt at the rate of one gramme a day, or fifteen grains for two years, in angina pectoris, and he is confident that he has obtained several definite cures.

A Curious Case of Hiccough Cured by the Extraction of Nine Needles from the Epigastrium.

Liégeois has described in the *Revue Méd. de l'Est* a case of intractable hiccough in a nervous and irritable woman, aged twenty-one. The paroxysm lasted twenty-four days, and was so violent that the whole body was shaken, and the noise could be heard at a distance of forty yards. Bromide of potassium and ether had been given without success. Chloral and hyoscyamine produced a temporary improvement, but the paroxysms reappeared after a time. Opium and atropia were then administered, and the hiccough ceased for about a month, when a new attack occurred. Five months later, a small abscess formed in the epigastric region, and a needle, which projected through the skin, was extracted by the patient's sister. An incision was then made by Dr. Liégeois, who found eight other needles in the subcutaneous tissue. This operation was followed by a complete cure, but the author is unable to state whether the needles had been swallowed or introduced under the skin by the patient herself.

Systematic Examination of Wet-nurses for Preventing the Transmission of Syphilis.

The *Med. Record*, May 30, says: Several years ago a bureau was started in Moscow (*Jahrbuch für Kinderheilkunde*), where wet-nurses could be examined by specialists with reference to old or recent syphilis. The examination was intended to be a very searching one, on account of the latency which characterizes this disease, and the possibility of future outbreaks in such cases. A certificate of immunity was withheld if suspicious glandular swellings, scars in certain places and of a certain character, suspicious pigmentations, or swellings of the bones were present, or if there was a history of repeated miscarriages. The condition of the nipples was especially noted. Of 490 women, who were examined in the course of three years, seventeen per cent. were refused certificates of immunity. In an additional four per cent. of cases, the evidences of syphilis were unmistakable. It is gratifying to know that this bureau appears to have met with the approval of Russian physicians. But in our own country the establishment of such an institution is hardly practicable.

Simulo in Epilepsy.

In the first number of *El Boletin Medico*, published at Trujillo, Peru, Dr. Larrea y Quezada recommends the treatment of epilepsy by an Indian remedy "simulo," which is the fruit of *Capparis Coriacea*, a plant indigenous in Peru. *Melocharn*, a conserve made from another plant belonging to the same natural order, is also used in epilepsy. Of the powdered simulo, 45 grammes are mixed with 500 grammes of the sweet sacramental wine, and of this a wineglassful is to be taken night and morning. In his own case, this treatment was most successful. As a boy, aged 13, he had fourteen epileptic attacks, preceded by a distinct aura, but under this treatment the fits left him. Since he has been in practice he has employed simulo extensively in epilepsy, hysteria, and other nervous diseases.

A Formula for Ring-worm.

Dr. Henry Browne gives it to us in the *Brit. Med. Jour.*, June 6:

℞. Sodæ hyposulphitis, ℥j.
Solve in aqua, fl. ℥viij.
Et adde acidi hydrochlorici, fl. ℥j.
For outward use only.

The use of this lotion, as a water-dressing covered with oiled silk, and accompanied by daily washing in soft soap and water, has proved perfectly satisfactory.

An Ointment for Sore Nipples.

Groussin (Eclraireur Pharm.; Lyon Méd., N. Y. M. J., June 20, 1885) recommends, for application to sore nipples in nursing women, the following ointment:

℞. Sacch. alb., ℥j.
Zinci. ox., ℥j.
Acaciæ,
Glycerinæ, āā ℥j.
Mft. ungt.

Correspondence.

The Communicability of Scarlet Fever.

Eds. Med. and Surg. Reporter:—

I noticed an article in the last number of the Reporter, on "The Communicability of Scarlet Fever through a Third Healthy Person," and, thinking my experience may add something to the literature of the subject, I write this hurried note. In the fall of 1878 Mrs. G., of this place, visited friends some fifteen miles or more from here, staying two or three weeks.

Previous to that time there had been no case of scarlet fever in this neighborhood, and no epidemics of the disease for several years. There were some few cases in the community where Mrs. G. was visiting, but, as subsequently learned, not seemingly of a malignant character. In about a week or ten days after her return, two of her little grandchildren were taken with the disease in so mild a form that, if it had not been for the throat-trouble and the peculiar pasty condition of the tongue, it would hardly have been recognized as scarlet fever. The cases progressed favorably and the patients were soon well.

In the meantime, a family living about one or two hundred yards away from Mrs. G., and whom she visited soon after her return, were taken with the disease, in all its virulence, one of the children dying in a few days, and some five or six others had the disease with its unpleasant sequelæ, and tardy convalescence. These children were *never* outside of their own door or yard, and the only possible communication was as above mentioned. In addition to this, my own little boy, as in the case of Dr. Hewetsen's, climbed on my lap after my return from seeing Mrs. G.'s grandchildren, and in the usual time the disease developed, and the child died in a few days. My other children also had it, but recovered, and the disease became general, spreading far and wide throughout the community.

In the fall of 1879, when there had been no known cases of scarlet fever for six months at least, a woman came on a visit to a family in another part of my field of practice, from a place some thirty or forty miles away, where scarlet fever was prevalent. The usual result followed in the family she was visiting. Every child in the family—seven—being attacked by malignant scarlet fever. All recovered, however. The disease spread, and was of the most malignant type I ever saw. One bright little fellow died in less than ten hours after he was taken, or at least after he complained of being sick, another in eighteen hours and so on. I hope to be spared from ever passing through epidemics of scarlet fever such as I have mentioned.

It seemed to spare neither age, sex nor "previous condition of servitude." I saw cases that were well-marked in persons as old as sixty years and more, and all ages younger than that.

I never knew a nursing child to die of scarlet fever, and regard the danger, other things being equal, as slight, even when malignant, after the age of puberty. Parturients, however, should be excepted. Since that time I have never had a doubt in regard to the communicability of scarlet fever.

In this connection, it may not be out of place for me to give a short similar testimony in regard to diphtheria. Mr. M. and his wife, parents of a large family, all of them at home, except the two oldest daughters, married, went on a visit to one daughter, married, living not far from Wheeling, West Virginia, taking their youngest child, a boy some four or five years old with them. Whilst there he contracted diphtheria, which was prevailing there, and died after a short illness. The heart-broken parents buried their baby among strangers and returned home.

There had not been a case of diphtheria in this country for a long time, although scarlet fever was epidemic, but in a week or two diphtheria, in its most malignant form, broke out in Mr. M.'s

family, and four out of six remaining at home died. Mr. and Mrs. M. said they brought nothing with them that had been about the first child that died, so that the disease must have been carried in their own clothing.

WM. F. MITCHELL, M. D.

Addison, Pa., June 29, 1885.

Facial Erysipelas.

EDS. MED. AND SURG. REPORTER:—

This disease has long been known by various appellations throughout the civilized world, and yet comparatively little is known of its ætiology, and there is room for improvement in the treatment. It was formerly treated entirely as a local disease; but the old barbarous treatment with caustic applications has deservedly fallen into disrepute. Many are the cases who suffer from the intense burning and disfiguration of the face resulting from facial erysipelas; and in some cases life is destroyed. And yet, many of the sages of our profession seem to regard it of little importance, and lecturers in our colleges give it a mere passing notice. In the REPORTER, February 21, 1885, there appeared an article on pilocarpine in this disease. In another, February 7, a member of the profession reports a case of facial erysipelas cured with local applications of ext. jaborandi, fld. ℥j.; tinct. opii and glycerine, āā., ℥ss: preceded by a purgative, which of, course should always be given when needed. Of course, we cannot doubt the truth of his statement; but that there are cases of this disease not amenable to local applications of any drugs yet employed, is self-evident. It is not my purpose to set forth anything new, or to exhume anything ancient in the treatment of this disease, but if possible to discover some mode of treatment that will arrest the course of the disease more rapidly, and without the deleterious influence on the teeth of tincture of iron, which is now our "sheet anchor." I should be glad to have the experience of any member of the profession who has used jaborandi or its alkaloid in this disease—the dose given, interval between doses, and how long continued. In case of nausea and vomiting, which usually follow large doses of jaborandi, what are we to do? I think we ought to report the failures as well as the successes. I have heard of cranberry poultice being used in this disease. Has any one tried it? If so, is the result due to the heat and moisture, or to some therapeutic property contained in the berry?

I will ask your indulgence for a brief period, while I give my experience with jaborandi in a case of facial erysipelas. Was called to see Mrs. D. about 3 p. m.; age 35, medium height and weight, with neither history of any hereditary disease, nor previous attack of erysipelas. She complained of intense pain in the head, face swollen, discolored, and exceedingly sensitive to the touch. The swelling and discoloration extended from a point just below the left eye, over the entire side of the face and nose. Temperature 105°, pulse 120 per minute. I ordered internally, ext. jaborandi fid. gtt. xx. every hour, and locally, ext. jaborandi, fld. ℥j., tinct. opii, and glycerine āā ℥ss., keeping the face moist with this preparation. I returned about 9 p. m., finding the patient still suffering as before, with the addition of nausea and vomiting. I succeeded in checking the vomiting by discontinuing the jaborandi a short time and using bismuth subnit. I continued this treatment for three days, giving the patient all the jaborandi her stomach would tolerate and applying it locally as at first. The disease continued to spread, now covering the entire face, ears and sides of the neck. The temperature continued as high as ever, and in fact the case began to assume a serious aspect. I ordered tinct. ferri chloridi gtt. xx. every hour. In twelve hours the fever abated a little, and the patient was more comfortable. The interval between the doses was lengthened to two hours. In three days the temperature was normal, and the swelling and discoloration nearly gone.

The iron was continued a few days in smaller doses at longer intervals, and was followed by elix. quiniæ. ferri et strychniæ, as a tonic. The patient made a complete recovery without any discoloration of the face. It is unfortunate both for us and our patients that all cases do not terminate thus happily. While I was treating the case reported, I was also treating a case which finally succumbed after an illness of about eight weeks. This patient was treated with tinct. of iron in large doses from the first. Some cases cannot take tinct. of iron, and pills of "reduced iron" may be used.

J. H. MOORE, M. D.

Spring Hill, Johnson county, Kansas.

NEWS AND MISCELLANY.

Death of Armand Peltzer. (The Finale of a Great Crime.)

A recent number of *La Belgique* records the death of Armand Peltzer, who, along with his brother Leon, was found guilty of the murder of William Bernays, the eminent Belgian advocate. The details of this crime, which was designed by Armand, now deceased, and carried out by Leon, were of the most sensational character, transcending the most exciting narratives of Braddon or of Allan Poe, and were fully described in its pages for February, 1883, p. 106. The two brothers were sentenced to death, but, owing to the insuperable objection of the King of the Belgians to capital punishment, had the capital sentences altered to imprisonment for life. They were employed as bookbinders, and Leon, being of a coarser organization, appears to have reconciled himself to the situation. Armand, ambitious, unscrupulous, crafty, and fond of pleasure, felt keenly the loss of social position and enjoyment; he got thinner and weaker, and gradually fretted his life away. Last week he was attacked with pulmonary hemorrhage, to which he quickly succumbed. Neither of the Peltzers had to complain of material discomfort, and, in fact, their treatment all along and at the close illustrates the present unhealthy moral atmosphere of social life in some parts of the Continent. Here they would have been convicted felons of the more heinous type, known by their prison numbers, dressed in prison clothes, and seeing their families at distant intervals, and separated by solitary confinement.

In the Belgian prison the Peltzers used to see their families whenever they liked, in a comfortably furnished room and in their ordinary clothing, which they used to put on for the purpose (*revetir les habites burgeois pour reçevoir la visite*). Leon had a taste for reading, and in his room were "The Letters of Paul Louis Courrier," "The History of Napoleon the First" by Lanfrey, and a number of works of fiction, travels, and history, lent to him by various private friends. He requested to be supplied with the *Revue de deux Mondes*, but the Director of the prison declined to permit this. In these countries the death of notorious criminals either passes unnoticed, or, at most, is briefly mentioned in the journals. The closing events of Armand Peltzer's life are described at length, and read very like the deathbed scene in "Traviata." All that was said and done by himselt and by the others present, is recorded with much unction, constituting a regular apotheosis of crime. The newspaper account concludes by mentioning that the remains of Armand Peltzer are to be removed from the prison of Louvain (where he died) to Berchem, the fashionable cemetery of Brussels, where they are to be interred in the family vault.

The Waking Power.

The *Popular Science News* tells us that an old problem of the psychologists has been revived by a letter to *La Nature*, written by a French business man, who mentions that for years he has been in the habit of waking himself at any hour in the morning that he wished, simply by impressing upon his mind, before going to sleep, the fact that he must awake at that hour. He says, further, that he seldom varies five minutes from the moment which he has assigned himself. The editor of the journal adds: "We have a distinct recollection of many instances in which we have ourselves tried the experiment with success; and at one time, when it was necessary for a considerable period for us to wake on certain days of the week at a very early hour, to take the first train to the place where our services were then needed, we had an opportunity of studying the circumstances under which this peculiar species of self-control is most easily exercised.

"Whatever part of our mind it might have been that took charge of waking us, seemed to begin its count of the hours from the time at which we composed ourselves to sleep; and, if we did not inform ourselves of this, our conscious reckoning was correspondingly uncertain, and the effort to wake vague; but, if we took a clear note of the time in the evening, we could sleep peacefully through the whole of the allotted interval, sure of being aroused at or near its expiration.

"Another condition of waking we found to be the occurrence of some small external event, through which, as it were, the internal effort could take effect upon our senses. A very trifling circumstance—the flutter of a leaf outside the window, the chirp of a bird, or any other of the unnumbered sounds of early morning—was sufficient, if it happened at the right time, to wake us by a sort of magnifying process, which at that moment gave the power of starting up by a noise which would at other times be unnoticed; but without such sensible impression, we think we should not have waked. In fact, on one or two occasions we remember to have been impressed with a dim consciousness of waiting for something to happen before waking; and a moment later a trifling sound would open our senses with a little shock. To the necessity of waiting for this impression, small as it might be, we were disposed to attribute the variation of a minute or two, either way, from the exact moment assigned for waking, which might otherwise be kept with exact punctuality."

Aunt Betsy's "Simpsons."

A writer in the *Columbus Med. Jour.*, for July, says:

One day, not long ago, I was called to see an old colored woman of the "fo'-de-war" type, black as the ten of spades (which is ten times blacker than the ace), extremely voluble, and anxious to impress me with the importance of her "simpsons," of which she was determined I should have a full and clear understanding before I prescribed.

"My mis'ry, doctor, wuks right up from bofe my legs, an' up through my stummick, and den crosst my bowels, all a shaky an' a wig-waggy! Den my right shoulder, doctor. *Law sakes!!!* Dat yer mis'ry in my right shoulder pow'ful bad sometimes. Den I has shootin' pains all up an' down my spine; dreadful! an' lumps in my flanks, an' a burnin' all over my right side, an' a *roarin'!* yes, honey, an' awful roarin' in my head, an' de bones all loose in my head. Den I has pains in bofe shoulders, an' my insides dey workin' jes' like maggots!! an' I has a draggin' in my stummick, an' my sistum very bad. Ef you b'lieve me, doctor, dar's a patch of mis'ry in de small o' my back, an' when I stan' up 'pears like my insides dey stickin' to my spine! an' a wallowin' in my head, an' I don' got no appetite, an' 'pears like every minute I gwine throw up my insides. I can't drink no fresh water; drinks all my water *biled!* In de night you can hear my head a roarin' an' a buzzin', an' den my bowels gets to workin', an' you can hear 'em a crackin' an' a blabbin', an' dey all a shakin' an' a trimblin'. Den I has a hotness in de bone o' my neck; yes, doctor, right in de bone o' my neck, an' at fuss a *pang* riz up right acrost my neck, an' riz an' *bust!!* I knowed it wa'n't a blood-vessel else I died *sure*."

The Pennsylvania State Board of Health.

At the first meeting of the State Board of Health, held at Harrisburg July 2 and 3, immediately after the organization of the Board was completed, the following resolutions were unanimously adopted:

Resolved, That the State Board of Health desires to express its hearty approbation of the energetic measures now being prosecuted by the health authorities of the cities of Philadelphia, Pittsburgh, and Erie, in order to avert the threatened invasion of Asiatic cholera during the present summer.

Resolved, That in house-to-house inspection, faithfully and fearlessly performed, it recognizes the only reliable means for discovering the actual

sanitary condition of a city, and that the appointment in the city of Philadelphia of an officer who shall devote his entire time to the work of disinfecting such premises as are reported by the inspectors to be a source of danger to the public health, affords reasonable ground for the hope that with proper pecuniary support from the City Councils, these efforts will there be crowned with success.

Resolved, That the Board of Health regrets the suspension of the order of the Board of Health of Philadelphia, directing the disuse of filling up of wells of drinking water in built-up parts of the city, believing that all such wells, if not already polluted, must shortly become so, thus constituting a constant source and menace of disease.

Resolved, That that this Board pledges to the Boards of Health, Health Commissioners and Health Officers of the cities aforesaid, its vigorous co-operation in all action designed to avert pestilence from and maintain a high standard of public health in, the ports of entry of this commonwealth, and will unhesitatingly use for this purpose the powers which the Legislature has conferred upon it, and will also avail itself of such advantages as may accrue from its relations to the National Board of Health and the Boards of Health of neighboring states, to the same end.

Resolved, That in view of the lateness of the season, and the threatening character of the intelligence from the south of Europe in regard to the progress of Asiatic cholera, the Boards of Health or health officers of the aforesaid cities be requested to send at once to the secretary of this Board copies of their regular reports, together with such other information as in their judgment it may be important that this Board should be in possession of, without waiting for the preparation of blanks by this Board.

Medicine in Greece.

The *London Med. Times*, May 16, 1885, tells us that a correspondent of the *Semaine Médicale* (May 6) gives a satisfactory account of the state of medical education in Greece at the present time. The Faculty of Medicine of Athens, he observes, is the most important of the two Medical Schools in the East. (The other, that of Constantinople, is especially devoted to the instruction of military doctors for the Turkish army.) It is well managed, and is provided with clinics for the complete instruction of the numerous students who frequent it, not only from the different parts of Greece itself, but also from the entire East. The old laboratories have been replaced by new constructions; and the Hellenic government has determined upon founding a new laboratory for the physical sciences, and a large establishment for anatomical and microscopical researches. The study of medicine extends over four years, and for the degree of doctor an examination has to be passed at the end of the second year, and another at the end of the fourth year. But the diploma does not confer the right to practice, for which another year has to be passed at the hospitals, and a third examination undergone. Athens possesses two important medical societies, the Society of Medicine and that of Hygiene, while the Parnassus, which is a scientific and literary society, has a section devoted to medicine, physiology, anthropology, and physics. There are two medical weekly journals, and a monthly one, published by the Society of Hygiene. A Greek Medical Congress has also been established. Its first meeting was held at Athens in 1882, and the next is to take place at Constantinople in 1886.

The Yellowstone Park as a Winter Sanitarium

From my own observations, and from inquiries made on the spot, I am of opinion that the Yellowstone National Park possesses, in a high degree, all these essential conditions. In elevation above the sea it surpasses Davos; the great plateau of the park is between 7,000 and 8,000 feet above sea-level, while it is stated that not one of the narrow valleys dips below 6,000 feet. The mountain ranges, partly surrounding and partly within the park, rise to heights of from 10,000 to 12,000 feet. I should anticipate, therefore, that all the advantages which, as a winter resort for invalids, Davos possesses from its elevated position, would be enjoyed even in a greater degree in the Yellowstone Park. The period of permanent snow is longer, so that invalids could remain there probably until the end of April, whereas the melting of the snow generally compels them to leave Davos early in March, when the climate of the valleys is peculiarly unfavorable for chest complaints. It is to be expected, from its greater elevation, that a still clearer sky and a larger proportion of sunny days would be experienced in the Yellowstone Park, while the wholesomeness of the air would be still more marked, owing to its comparatively greater freedom from zymotic matter.—*From "A Great Winter Sanitarium for the American Continent," by Prof. Edward Franklana, in Popular Science Monthly for July.*

Medical Mission Work in China.

From the report for 1884 of the Hang Chow Medical Mission in connection with the Church Missionary Society, it appears that the total number of out-patients attended during the year was 2,920 and of in-patients 235, patients visited at their homes bringing up the total of those who were relieved by the mission to 4,707. Anæmia, as in the case of the Chin-Chew Hospital, the work of which was noticed in a recent issue, formed a large percentage of the cases coming under treatment. It is especially common amongst women, and is easily accounted for by the following causes: Marrying too young, hemorrhagic losses during confinement, suckling their children for three or four years, and their cramped feet, which prevent them taking proper and sufficient exercise. Diseases of the skin and digestive system and malarious fever also each contribute a large percentage of patients. A new hospital, comprising a refuge for opium smokers, which was its *raison d'être* when commenced some thirteen months ago, and a medical school are almost completed, and will, it is expected, be opened in a few months.

Therapeutical Inventions.

The McIntosh Batteries.

The McIntosh Galvanic and Faradic Company,

of Chicago, attracted much attention at the New Orleans Exhibition for their fine display of goods and the improvement they have made in electrical articles generally. They received first medal for fine displays of electrical goods, and first medal for their combined solar microscope and stereopticon. Dr. L. D. McIntosh, the inventor, deserves great credit for arranging and making this display, because he met in competition the electrical inventions of Europe and America and took the first medal.

STAUFFER'S UTERINE EXAMINING INSTRUMENTS.

These instruments are of hard rubber, the specula with a high internal polish, not breakable, admirably arranged for carrying in the pocket without occupying much room, and very durable. We have used them for years, and prefer them to any others we have tried. A descriptive and price list may be obtained of the manufacturer by addressing care of this journal.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended June 13, 1885.

Long, W. H., surgeon. Granted leave of absence for three days, June 18, 1885.

Fessenden, C. S. D., surgeon. Leave of absence extended seven days on account of sickness, June 24, 1885.

White, J. H., assistant surgeon. Granted leave of absence for twenty-one days, June 23, 1885.

Items.

—Pasteur's method of vaccination for cattle-plague has proved completely successful in India for elephants, horses, asses, cows, buffaloes, and sheep.

—Oxide of zinc, according to Professor Peterson, of Kiel, is just as *good as iodoform in the treatment of wounds*, is not poisonous, is cheaper, and does not smell offensively.

—The *Pacific Medical and Surgical Journal* states that the law regulating medical practice is a failure, because juries cannot be found who will convict, "even though they be the lowest Chinese charlatans."

—Nasal polypi, it is said, can be readily cured by the injection of a solution of a scruple of tannic acid in a fluid drachm of water. Ten to twenty minims of the solution are to be injected into the polypus. The polypus shrivels, dries up, and comes away without pain or trouble.

—An unusual bathing fatality is reported from Greenock (Scotland), where a boy, while bathing in a stream, fell on his side against a broken bottle. The abdominal walls were cut through, and the intestines protruded. He was conveyed to the infirmary, but succumbed to his injuries within forty-eight hours.

—Dr. Pasquale Ferraro has recently (*Il Morgagni*, February and April, 1885) conducted a research on the comparative pathology of diabetes, in the Anatomical Institute of the University of Naples, under the direction of Prof. Schrön. It results that diabetes mellitus may develop spontaneously in the dog, and gradually intensify until it becomes fatal. The etiology, clinical course, and histological anatomy of the disease, are similar in the human and canine species.

—Chicago is to have a charity that will be a credit to the philanthropy of its founder. March 7, the will of Mrs. Clarissa C. Peck was admitted to probate. By the provisions of this will, the sum of $125,000 is appropriated to the purchase of ground and the erection and furnishing of a building to be known as a home for incurables, and the balance of an estate amounting to upward of $600,000 is given as an endowment for the same.

—To the Sheffield Medico-Chirurgical Society, Mr. Edward Barber showed a lad, æt. 15, the subject of a most marked form of pigeon-breast; the prominence of the lower portion of the sternum, with its attached cartilages, was extreme. The mother said that the boy was quite right until two years of age, when the breast changes began; they have been rapidly increasing of late. There is no deformity of the spine, and in other respects the boy seems well-nourished.

—Under the name of "Transverse Anterior Club Foot," M. Mollière, of Lyons, has described a deformation of the foot in which the first phalanx of one or several toes is in a position of forced extension, while the second and third are flexed. The arch formed by the heads of the metatarsal bones is flattened in consequence of the relaxation of the ligaments, and the patients complain of much pain after exertion. The symptoms are relieved by the use of an India-rubber pad, placed under the head of the second metatarsal bone, and the toes soon resume their normal position, but the treatment must be continued during several months.

Personal.

—Dr. F. Le Sieur Weir has resigned from the Medico-Chirurgical College of this city.

QUERIES AND REPLIES.

MESSRS. EDITORS:—

Is the common crude petroleum poisonous when taken internally, say in quantity of two or three ounces?

MARCIPAN.

Ans.—If the inquiry means whether it is liable to produce *fatal* results, we believe we may answer in the negative. Petroleum taken in such quantities would be partly vomited, partly passed off by the bowels, and the kidneys.

MESSRS. EDITORS:—

I notice that several prominent makers and venders of disinfectants say their compounds are endorsed by the Public Health Association. I cannot learn what the Public Health Association is. Is this a deception upon the public to boom their compounds? Please advise a reader.

MEDICUS.

Ans.—The title "The Public Health Association" is certainly very vague, and we believe is not the full name of any scientific body; we presume, however, that its employment is rather out of carelessness than an attempt to "steal thunder."

Dr. J. K. R., of Mo.—We should not care to recommend one college above another. There are at least a dozen in the country which stand at the top, and are equally good.

SURGICAL TREATMENT OF INFANTS.*

BY DEFOREST WILLARD, M. D.,

Lecturer on Orthopædic Surgery, University of Pennsylvania, Surgeon to the Presbyterian Hospital, etc.

Your committee having invited me to speak to you to-night upon the Surgical Treatment of Infants, I purpose to confine my remarks chiefly to personal experiences in the means of relieving the principal surgical difficulties which are met with during the first two years of life. If the subject shall occasionally lead me to mention older children, it will be because the line between infancy and childhood is not a marked and well defined one.

As you are all active practitioners also, it will be unnecessary for me to dwell on detail, and I shall only touch upon practical points in treatment. The surgery of childhood as compared with that of adult life, is, aside even from congenital defects, sufficiently marked and distinctive to entitle it to separate consideration.

First of all, must the children's surgeon acquaint himself with the anatomy of the child. This is rarely done, as the ordinary adult dissections during a college course give little idea of the size and position of the individual elements as seen in the infant. In consequence of ignorance upon this practical point, many grievous failures have occurred. After unusually large opportunities for the study of both normal and abnormal tissues in the diminutive frame, I am still frequently surprised to note the exceeding smallness of different organs and canals.

Another essential element in the surgeon is tact in the management of the little ones, especially when dealing with those between the ages of two and ten. In hospital cases, but little history is attainable, and much depends upon quick perception. Naturally fearful of pain, the patient's mind must be diverted and engaged, or great difficulties in diagnosis will often occur from the fright and struggling. The operator not in sympathy with children, can never secure their confidence. Much will often be gained by quiet observation. It is not a month since my opinion, which in the first few moments of the consultation had been favorable to tracheotomy, was changed by five minutes' close watching, and the result proved the correctness of the procedure. To the person, however, who will carefully study individuality as well as disease, no department of medicine offers so pleasant a return for his labors. My personal experience with children has perhaps made me more hopeful in regard to the power of such individuals to endure pain, shock and disease, than would be indicated by the expressions of other authors; but to me there is no domain of surgery so attractive and gratifying as the treatment of children below the age of puberty. Their natural condition is that of hopefulness, and as soon as the depressing influence of shock, pain or fear is removed, the normal resiliency of mind and body asserts itself with such rapidity that the results are often surprising.

Again, a child has only inherited taints of constitution to contend against; his viscera are ordinarily in a healthy condition: an adult has not

*Read by invitation before the Philadelphia Obstetrical Society, June 4, 1885.

only hereditary, but all the acquired vices occasioned by misuse or abuse of any organ or sets of organs, a circumstance which often turns the scale in the struggle between life and death. Take, for example, the single instance of the outraging of tissues by either the moderate or the excessive use of alcohol, and every surgeon will testify that even slight wounds may, in such an individual, quickly develop a fatal attack of mania-a-potu.

Tetanus is not more frequent in infants than in adults, notwithstanding the tendency of the former to nerve excitability.

In regard to anæsthetics, my experience is that great benefit is obtained by the use of ether when pain can thereby be prevented. In the first weeks of existence, I admit that a feeble vitality would contra-indicate its use, although I have successfully administered it to a three-days' old infant. After the first or second month, I see no reason why we should needlessly inflict pain upon an infant simply because we can control it by brute force. In the examination of fractures great suffering is often inflicted by careless and frequent manipulation, and unless the diagnosis is easy and positive, unconsciousness should be produced. No case of bone injury should ever be passed by undiagnosed, when ether will solve the question.

In the opening of abscesses, the "primary influence" of ether is so readily obtained that it should be brought into use whenever practicable, as keenness of pain can thereby be avoided.

Fear plays an important part, and may depress the child's system even more than pain, hence great caution should be observed that all knowl edge of any operative procedure should be guarded against. When the day for action arrives, let the surgeon quietly and gently state to the little one, if it has arrived at years of reason, just what it is proposed to do, at the same time assuring him that no pain will be experienced; and if such words be followed by firm, speedy, and judicious management, much agitation and fear will be avoided.

All preparations should be made out of sight and hearing of the patient, and instruments need never be seen by him, except when a strong impression is intended to be made upon the mind of a masturbating boy, requiring circumcision, in which case ether may also be omitted.

One word in regard to the method of anæsthetization. It is but natural that a child should be distrustful of any attempt to deprive him of con sciousness, a fear which is greatly increased by the injudicious and greatly to be condemned habit of many parents who systematically threaten their offspring with the expression, "the doctor will come and cut your head off." A few kind words will often quiet the agitation, and simple directions as to the method of breathing will save many minutes of struggling resistance. With very young children, the first smell of ether may be masked by permitting them to see cologne poured upon the towel, after which ether may be quietly added, and they will feel that it is a perfume that they are breathing. This device has frequently served me a good purpose. I always allow a good admixture of fresh air for the first moment, but when the child actually begins to cry, then quick action answers best. The towel should now be well saturated and held firmly over nose and mouth until two or three strong screams and inhalations will yield a full primary impression, which can be gradually followed up to complete anæsthesia with safety.

Should any symptoms of ether narcosis occur, it is so easy to depress the head of a child, or to perform artificial respiration by acting upon the ribs, that serious accidents are infrequent. Subsequent vomiting is very common, but is not persistent, and is easily quieted by a small hypodermic of morphia, a procedure which ordinarily brings quiet sleep to the patient. If the child is feeble, I always allow milk up to within two or three hours of the operation, and then administer wine or whisky in water immediately before giving the anæsthetic. Milk with lime water and whisky is usually retained within ten minutes after the first vomiting on rousing. In tedious excisions, not only should preliminary precautions be taken to secure against prostration by shock, but hot water bags should be ready for use, which with hypodermics of brandy, may succeed in tiding over a temporary depression, which would otherwise end in death. When the loss of blood has been great, especially in acute surgery, important assistance may be gained by transfusion, either of blood or of a warm saline solution.

Under the head of arrest of hemorrhage, I would strongly advocate the use of animal ligatures, since the pain often incident upon the removal of threads, greatly disturbs the needed quietude of wound and mind.

Thorough asepsis and antisepsis are especially valuable, since we not only secure the admirable results that are attainable by their use, but are also enabled to disturb the child with far less frequency. I am now treating a girl with a railroad crush of the leg, which would thoroughly have

justified amputation, yet which under corrosive sublimate dressings has not been touched but six times in as many weeks, even though extensive sloughing has occurred. Save upon one occasion, at the height of the process of tissue-death, the applications have been taken away perfectly sweet, and the child has the promise of a reasonably good limb. In my ante-*septic* days, I certainly was never able to carry a patient through such a process, and keep the temperature as has been done in this case, below 99½° all the time, and usually but slightly above 98°. With infrequent dressings, the irritation of the child is but slight, and if pain is also absent, contentment is the rule, under proper nursing.

I cannot too strongly emphasize the importance of this latter condition. A kind, quiet, gentle nurse is one of the most valuable assistants in the real progress of the case, especially during the first week following the operation. Such care cannot be delegated to untrained and careless people, hence it is absolutely necessary that children should be in separate hospitals or in separate wards, under the best of care-takers. Even in private practice, the mother is rarely the best nurse for a child past two or three years of age, and a skilled attendant answers best. In hospital practice, I have often been surprised to see how contented and patient the majority of children of even three years of age will become, if the mother maintains a judicious absence and the nurse is efficient and kind.

Another point which I wish most emphatically to emphasize to-night is the fact that congenital defects are most inexcusably and persistently neglected by even good practitioners, either under the mistaken opinion that nothing can be done, or that a later period will be early enough. The consequence is that many unfortunates become helpless and hopeless cripples by their physician's advice, since, passing out of his sight and mind, the neglect engendered by his direction, "wait," is fostered by parents, ever ready to postpone a dreaded day.

Turning to some of the special surgical diseases of infants, I would say that it is my intention to simply touch upon a few points of treatment without regard to definite arrangement or order, since to consider almost any one of the conditions in full would require an entire evening's discussion.

In a new-born child, the first most probable trouble, requiring surgical relief or treatment will be *imperforate anus* or *rectum*. Such a condition is not improbable when we remember that the intestine is formed as a closed tube. If the malformation be simply one of occlusion of the anus by a membrane, it would seem to be the easiest of procedures for any practitioner to make an opening; yet I have seen children permitted to die with the entire ischio-rectal fossa and perineum bulging with retained fæces, when a simple puncture through a membrane closing an otherwise normal anus would have given immediate relief. This timidity may perhaps be explained by the fact that occluded anus and imperforate anus are confounded with imperforate rectum, and the case is given up as hopeless. In imperforate anus, the operation is still a simple one, since a crucial incision together with stretching of the mucous membrane to the skin, and subsequent dilatation with the finger or probe, is all that is required.

When the anus is normal and patulous, but the rectum is occluded by a membrane, or is actually absent, then a much more serious condition presents itself, the difficulty increasing in proportion to the extent of the deficiency. Should no meconium be passed within the first twenty-four hours, a careful search should be instituted. The little finger or a catheter passed into the anus will detect the obstruction, or if the anus be absent, the vagina, if present, may be explored for the abnormal fistulæ. As soon as the presence of fæces can be discovered in the fossa, a careful dissection should be made, keeping well backward, so as to avoid the vagina or the urethra and bladder. A catheter should always mark the position of the urethra. There is but little danger even in deep incisions, if the region of the coccyx and sacrum be followed. The gut found should be drawn down as far as possible, and secured, a channel being maintained through the rectal region, if necessary, by the finger or by bougies, the latter of which should not, however, be retained constantly in position. There is much more danger from subsequent hemorrhage if the external incision be free, and no fear need be entertained about the ultimate retention of the fæces; if the child escapes peritonitis and other inflammations, good control of the bowel is always secured, in fact, the chief subsequent danger lies in the formation of stricture. When the length of the bowel will not permit it to reach to the site of the anus, the new opening may be made nearer to the sacrum. Should no trace of the rectum be found within two inches of the anus, it is unsafe to further explore a region where peritoneum would be liable to injury; either left inguinal or left lumbar colotomy should

be performed. The right groin is to be selected if there are evidences of absence of sigmoid flexure. The left inguinal position gives a better subsequent opportunity of passing the bougie downward into the rectum, and thus establishing a proper anus. If the colon is full, it will not be difficult to find. In cases of doubt, its distension by air or water through a hypodermic needle would determine its termination. Abnormal openings into the vagina, bladder, or urethra rarely require early operation, but in non-retention of fæces at a later age, Rissoli's plan of procedure is a good one.

Later in childhood, the surgeon is often compelled to treat another condition of the rectum, namely, prolapse. This, if excessive and non-yielding to replacement, astringent applications, hot water bathings and general constitutional measures, must be cured by the production of linear eschars by nitric acid.

The genito-urinary organs may also require attention immediately after birth. A simple occluded urethra is easily relieved by the careful introduction of a sound or catheter. *Epi-* and *hypo-spadias* and *extrophy* of the bladder should not be allowed to go on to adult life without relief. As soon as the child has passed its dentition period, a plastic operation should be attempted for relief, since the mental and moral effect of such a deformity has often a marked influence upon the lives of the unfortunates. *Adhesion* of the *vulva*, or nymphæ, should not be overlooked, since not only does the nervous system suffer, but the parts may be improperly developed. Separation can almost always be accomplished by the finger or by a probe. An absolutely *imperforate hymen* should never be allowed to exist if discovered, since if permitted to impede the menstrual flow, at a later period, serious and even fatal results may follow its division, if the uterus and fallopian tubes have become dilated by the imprisoned secretion. *Imperforate vagina* should receive at least careful diagnostic attention to detect the presence of a uterus, and if not absent, fuller development will be secured if the passage can be opened during the first few years of life. With a catheter in the urethra and a finger in the rectum, a careful operator can explore safely. I have met with several cases in which the *penis* was preternaturally *short* and illy-formed, the body of the organ during flaccidity being almost entirely concealed in the fatty tissues of the pubis. In such instances I have removed the prepuce during the first three months of life, and have cut away all restricting bands of skin and connective tissue, sometimes even drawing beneath the penis an extra flap of skin when the corpus spongiosum has been short and dwarfed. By such means the fullest amount of growth is encouraged.

Adherent and *contracted prepuce* or *phymosis* has been the subject of much discussion, in regard to its causal influence upon certain nervous manifestations. My views upon this subject have been already published,* and after two years of additional experience, during which time I have been brought daily in contact with this class of cases, I can reiterate what I then stated, namely, that while more or less adhesion is an almost constant and normal condition, yet that when urinary, choreic, paretic, or any other nervous symptoms develop, a careful investigation should never be omitted, since a direct relation will, in a certain number of cases, be clearly evidenced, and removal of the cause will speedily cure the manifestation. The fact that even circumcision does not relieve the symptoms is undoubtedly true in many instances, and I have never claimed that preputial adhesion and narrowing was anything more than one of several factors, which should be carefully scrutinized. I have only urged that its influence should not be overlooked, and when so simple an operation as stripping the prepuce from the glans by the thumbs, or possibly by the use of the probe, is all-sufficient, there can certainly be no argument against removing this one factor. My opinion in regard to the feasibility of drawing back the prepuce in young children, even when the opening seems scarcely pin-hole in diameter, has been greatly strengthened, and circumcision is only necessary when the simpler method described fails to secure a prepuce freely movable over a normal glans. Dilatation even is but rarely required, a few moments of continuous pressure soon revealing the mucous layer, adherent perhaps just above the meatus, which when loosened permits the head to pass through the opening, and the corona is freed with the thumbs. Should temporary para-phymosis occur, two probes or a hair-pin slipped beneath the constriction will easily permit replacement.

Congenital hydrocele rarely requires much surgical interference beyond an evaporating lotion of muriate of ammonia or alcohol, as a few weeks will often close the canal, if hernia does not coexist, a fact which can be determined by non-translucency and capability of reduction. Should the connection with the peritoneum fail to close, puncture with the application of a truss will

*Philadelphia Medical Times, June 30, 1883.

usually complete the cure. A hydrocele with closed canal is better treated by tapping and injection than by seton. The diagnosis between *encysted hydrocele* of the cord, *hernia*, and *undescended testicle*, is sometimes difficult; but if the surgeon remembers that the former is simply a cyst in some unobliterated portion of the peritoneal coat of the cord, that its rounded shape can be detected if it is pulled well down into the scrotum, that it is usually translucent, that the impulse is not as decided as in the case of hernia, that it returns to the abdomen only by being pressed upward, and not with a slip and gurgle, he will rarely be lead astray. A hernia may coexist with either of the above-mentioned conditions, but if non-adherent careful isolation will settle the diagnosis. Should the hernia become strangulated, or the non-descended testicle become inflamed and infiltrated, the most careful examination will be necessary. In retained testicle, its absence from the scrotum will be the first point in arriving at a decision, but even in such a condition, the organ might be within the abdomen and an encysted hydrocele present, or the testis might, as has recently fallen under my notice, slip into the tissues of the perineum, and be exceedingly difficult to discover. In the case just mentioned, it sometimes requires numerous manipulations to cause the missing organ to return to its place in the pouch. Should hernia and retained testicle both exist, a double purpose can be gained by drawing the latter down and pushing the former up, and then applying a truss. The successful retention of the organ within the scrotum is a matter of great difficulty, and removal is scarcely justifiable in young persons unless pain or inflammation ensues. Extirpation, if required in later youth, will probably not interfere with the procreative power of the individual, since one gland will supply all requisite material, and the affected one is practically useless from atrophy, even if it is not devoid of tubular structure. Traction is of little service, as manipulation tends to increase the sensitiveness of the organ. In prognosis it should be remembered that cryptorchism exists in nearly ten per cent. of males at birth, and that descent may occur within the next few weeks.

Simple *umbilical* and *inguinal hernia* should receive early attention, as, contrary to the rule in adults, a cure can often be effected during the first year of life by the persistent use of a truss. In young infants, I prefer the hard rubber variety as more cleanly. The instrument should be applied during the first few weeks of life, and continued for one or more years. The treatment of strangulated hernia does not differ from that of the adult, but in obstruction of the bowels, *intussusception* is so commonly the cause of the blockade, that unless violent peritonitis is present, laparotomy, with careful search for the invagination, offers the best hope of relief, and I am glad to say is rapidly growing in favor.

Meningocele, *Encephalocele* and *Spina Bifida*, are complaints that will early require the surgeon's attention, or at least his expression of opinion and his prognosis. If attached by means of a narrow pedicle, constriction with an elastic band is feasible, but unfortunately this pedicle is but seldom found. Injection of iodine following tapping is rarely successful, yet is worthy of trial in so hopeless a task. In a large hydro-rachis of the lumbar region, lately under my care, which resisted pressure, tapping, injection and constriction, I was strongly inclined to excise the thin sac, and attempt a plastic operation by drawing in toward the median line two flaps of skin from the lumbar region, leaving the vacancies to granulate. Soon after a consultation, in which I was dissuaded from my attempt, the tumor ruptured spontaneously, and death occurred in two days, although frequent tappings had never produced any nervous symptoms. I had then never seen a record of such a plan of procedure, but only last week I noticed in the Journal of the American Medical Association (vol. iv, No. 17, p. 466) that Mr. Robson had performed this operation with successful results in two out of four cases. Strict antisepsis was enforced.

Cephalhæmatomata are usually easily distinguished from encephalocele or meningocele, and also from the simpler tumor, caput succedaneum, the latter being exterior to the periosteum and more doughy. The blood in a cephalhæmatoma is always confined between the pericranium and the bone substance, and increases until the second or third day. The hardened ridge around the border of the tumor may give the sensation of an opening in the bone, but the orifice in meningocele is rarely as large as the base of the swelling mentioned. The peculiar crackling feeling upon pressure at a later period, is due to the new bone deposits beneath the periosteum. Absorption so generally takes place in three or four weeks, that aspiration or incision is unwise, even though antisepsis be thoroughly practised, unless in exceptional cases when suppuration is certainly present. Lotions have a good influence, at least upon the brain of the mother.

(*To be continued.*)

HOW SOON AFTER EXPOSURE TO SEPSIS MAY THE ACCOUCHEUR RESUME PRACTICE.*

BY GEO. F. FRENCH, A. M., M. D.,
Of Minneapolis, Minn.

The term puerperal fever embraces a group of essentially diverse affections, some of which are non-contagious, but the septicæmic variety is one which alone engages us in this discussion. Its formidableness may be inferred from the statement of Barker, that since 1740 there have been more than 200 epidemics of this disease—a humiliating fact when we consider that it is a largely preventible disease, caused too often by criminal negligence on the part of physician or nurse. It is more than thirty years since Semmelweiss proclaimed to the profession that the source of puerperal fever "is decomposing organic matter."

The great Simon sententiously observes, "Contagia are perhaps the most important of all the incidental physical influences which concern mankind."

Hebra says: "The discovery of Semmelweiss as to the chief source of puerperal fever, ranks in importance with that of Jenner."

In October of 1884, I addressed letters of inquiry to some of the most distinguished medical men in America and Europe, as to how far time is an essential factor in the cleansing process. In reply, Heger, Henry Savage, and J. Knowsley Thornton emphasized the importance of time as an element in the process; while Battey, Emmett, Goodell, Marcy, and Thomas, in this country, and Schröder, Martin, Nussbaum, Esmarch, and Volkmann, in Europe, affirmed the possibility of safely resuming obstetric or any surgical work, immediately after a thorough cleansing. The letter of Volkmann is especially significant. Under date of December 5, 1884, he writes:

"A surgeon who disinfects himself *well* can immediately after making a post-mortem or dressing a septic wound, undertake a laparotomy, do a trepanning, or dress a penetrating wound of the joint. Every morning, from six to eight, during the summer, I am obliged to give the students operations on the cadaver, and from ten to three I am busy in the hospital operating and dressing wounds, and I have never yet infected a patient. In the winter I have no operations on the cadaver to make. Comparing my results in the clinic, I can assure you that the mortality in summer is not greater than in winter.

"RICHARD VOLKMANN."

My own experience warrants me in making abdominal section on the day following exposure to sepsis. To show my confidence in the possibility of immediate and complete disinfection, I made the following experiments:

June 21, 1884. After laying open a dissecting abscess of the thigh, in a pyæmic patient, and stripping the limb with both hands till they were offensively drenched with the pus, I three hours later attended Mrs. M. in confinement, having first scrupulously disinfected myself.

July 22. In dealing with a case of pyo-nephrosis, before penetrating the kidney, I came upon a foul peri-nephritic abscess. Passing through this, the kidney was sought, incised, explored, and its grumous contents scooped out with the finger. The hand was so long engaged in this work, a more complete purulent saturation could hardly be conceived. In the afternoon of the same day I confined the wife of a physician, after stating to him the full extent of my morning exposure. In both cases the convalescence was perfectly normal.

February 11. I purposely infected my index finger with the ichor of an erysipelatous case, and after a careful washing with corrosive sublimate, inserted it into a fresh wound from which I had just excised a tumor.

In the rush of crowded professional work, some plead lack of opportunity to carry out the tedious and painstaking details of the disinfecting process; but how valid would such an excuse appear in the case of a wife or sister, or in the eye of the law? The present weight of evidence goes to show that the materies morbi of contagion, whether living or dead, is a non-gaseous material particle, capable of being acted upon and demonstrably susceptible of destruction. Its material nature makes it amenable to material and human influences.

To ascertain what time alone will effect in the destruction of septic matter, we may consider the well known property of contagia, of self-multiplication, and almost indefinite propagation under favoring conditions—a fact too frequently illustrated by the repeated outbreak in certain non-disinfected houses of diseases like diphtheria and scarlet fever after long intervals. Hildenbrand's coat retained its contagiousness for a year and six months. Pasteur has kept spores alive for twenty years. The resting spores of the bacilli are, of all forms of life, the most difficult to destroy, requiring a solution of corrosive sublimate $\frac{1}{3000}$; ordinary spores being killed by a solution of $\frac{1}{20000}$.

Steam or boiling water kills all bacteria in ten or fifteen minutes. Particles of contagion most frequently find lodgment on the hands—particu-

* Read before the American Medical Association, April, 1885.

larly under the finger nails. It is always possible, after the ordinary use of nail-brush or knife, to remove particles of dirt in which the microscope reveals living germs of possible infection. On this account I cut the nails short, and swab under them with a blunt instrument covered with cloth wet with some disinfecting liquid. I formerly used for this purpose five per cent. carbolic acid, but this made the sensitive flesh crack and pull away from the nails. I now use instead corrosive sublimate solution $\frac{1}{1000}$. All instruments are kept scrupulously clean, and the nurse is regarded as one of the instruments.

Volkmann's custom of wearing a linen coat to guard against emanations from the clothing is adopted. Cleanliness is a trait of personal character, and it is as impossible for some men to be scrupulously clean as for them to be orderly or systematic. Such physicians are by nature disqualified for ovariotomy, or even obstetric work. The closing sentence of Esmarch's letter epitomizes the discussion: "Time does not destroy septic dirt."

Hospital Reports.

A CASE OF ADDISON'S DISEASE.

REPORTED BY J. S. HACKNEY, M. D.,

Resident Physician West Penn Hospital, Pittsburgh, Pa.

Frederick Miller, German, æt. 41, an old soldier; occupation, peddler; family history, negative; personal history, while in the army he was wounded twice—once in the thigh and once in the abdomen. The history of the latter is rather uncertain, as there was no scar, and only the patient's friends say he was wounded, but could not define how or where.

Eight months previous to being admitted he began to feel ill, and seemed very weak, especially in the legs, his skin began to assume the dirty yellow color peculiar to the disease, and he looked, upon admission, not unlike an Italian who had been very much exposed to the sun. He continued at his work until three days before admission, June 11, 1885. At that time he took, as his wife expresses it, "a fit," which lasted about fifteen minutes, he being unconscious at the time. She also noticed at this time, while washing him, that in the region over his kidneys he had several brownish looking spots about the size of a silver dollar, to which she called my attention.

On May 11th he walked to the hospital, a distance of two miles. Upon admission he had no well-defined symptom pointing to any special organ being the seat of the trouble, except the discoloration of the skin. He complained of being very weak, and would throw up his food soon after taking it.

Upon examination I found as follows: Lungs and heart sounds normal; liver slightly enlarged, but not markedly so. The spots over his back as his wife had told me. The conjunctivæ were not discolored. Upon palpation and pressure over the kidneys and other organs, I could elicit no pain. He was but slightly emaciated. Pulse weak, but normal in frequency. There was no constitutional disease that could be made out. I ordered his urine saved, and found it negative in character, both as to quantity and quality.

I ordered him a tonic of tr. cinch. comp., before meals, and gr. v. pepsin after meals, with a diet consisting of beef tea, milk toast and a little whisky. In ten minutes after taking the medicine and his food he would throw it off. He thought it was the medicine that caused the vomiting, and to please him, I stopped it for two doses, but with no better results. I then changed the tr. cinch., for tr. iron, with 2 gtt. acid carbol., before eating, but with no better results. I then ordered a teaspoonful of milk with a few drops of whisky every half hour, all to no good, as he would throw it off.

I then ordered him an enema of warm milk; the syringe being hardly withdrawn, when to my astonishment it all came away. This was repeated three or four times with still no better results.

I had now exhausted my remedies, but as the patient was still strong enough to go to the water closet when necessary, I was hopeful.

On the evening of June 26th, I saw him at seven o'clock, when he was sleeping soundly, but somewhat heavily. Thinking it best not to disturb him, I left him without examination. Three hours later (10 o'clock), the nurse came to me and said, "I think that man will die before morning." I replied, "I think not," and went in to see him. I found him drowsy, but answered my questions intelligently. He was breathing rapidly, with a pulse weak but easily counted. I ordered some whisky, hoping he would retain it by giving a very few drops at a time. He said to me, "Let me get on the commode, quick, and then I will take it," and suiting the word to the action, he got up *without assistance* and got on the commode. He sat there about one minute, when he fainted, he was lifted on the bed at once, and in ten minutes he was dead.

Twelve hours after death a post-mortem was held by Dr. M. C. Cameron and myself, with the following results: An incision was made from mid-sternum to the pubis, exposing the whole of the abdominal and thoracic viscera. The viscera were examined as follows: Lungs normal; heart somewhat atrophied, with beginning atheroma of the mitral valves; liver slightly enlarged, but of a normal texture; spleen normal; small intestines normal; pancreas attached to the under and posterior surface of the stomach, otherwise normal; stomach, the mucous membrane indicated a slight but chronic inflammation; left kidney was somewhat enlarged and pale, otherwise normal; the supra-renal capsule was enlarged to the size of a hen's egg, and was very firm and hard in consistence, and was attached to the cardiac end of the stomach, so much so that it had to be dissected away with the knife. Upon cutting it open it grated upon the knife, showing calcareous changes taking place. It contained numerous cheesy deposits, imbedded deeply in a fibro-cellular, semi-transparent cortex. Right kidney the same, with

its supra-renal capsule much larger and firmer, and containing more cheesy and calcareous deposits, and firmly attached to the under surface of the liver, so that a section of the liver had to be cut away in order to secure the specimen. The mesenteric glands in the neighborhood were somewhat enlarged and tuberculous. Both specimens were saved and put in the museum of the hospital.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Discussion on Cholera. (*See page* 1.)

Dr. Bush, of Wilmington, Del., illustrated a point made by Dr. Hunt in reference to the removal of the well from the sick, by the following fact, which occurred in the Wilmington Almshouse in 1849.

The disease made its appearance with much violence and virulence, so that three-fourths of the inmates were attacked, and new cases were daily occurring. The floors of the house, which were old and emitted a disagreeable odor, were scrubbed, and both the floors of the house and the walls were washed with lime and chloride of lime —without effect; the disease went on. The inmates who were well were then removed to some shanties which were hastily put up on a lot across the road, and no new case occurred after their removal.

Similar instances were recorded by the English surgeons in India, where the removal of a camp had the effect of arresting the progress of the disease.

Dr. Bush also said that there was one point connected with this subject of special importance to Philadelphia, as well as to Delaware, viz.: the protection by quarantine established at the Capes of the Delaware. Last year there was a cutter stationed there under the direction of the Marine Hospital Service, also a hospital was erected. Having been removed for the winter, they should be restored early this season, inasmuch as there is such ready communication between all parts of Delaware and Philadelphia, that the protection of the former involves the protection of the latter, and indeed of all the country above. It is not sufficient to arrest vessels from foreign infected ports at the Lazaretto.

Dr. Ludlow described his remembrances of a severe epidemic of cholera which prevailed in Albany when he was a boy 12 years of age. He was also in the epidemic in Philadelphia in 1849, and, in fact, he had had experience with every cholera epidemic which had prevailed in this city. During the last epidemic he had charge of the cholera hospital. This was built in front of the almshouse, and from what he then saw he fully made up his mind that the disease could be prevented. Cleanliness, mental quietude, and absence of fear, are essential for prevention.

In regard to food, he said that in the severe epidemic in Albany, his father's family was permitted to eat everything that they had been accustomed to, with the exception of cucumbers; the reason for this restriction being that if any of them had gotten cholera, the neighbors would have blamed it on the cucumbers, and would have said that they deserved to have the disease. In subsequent epidemics, he had followed the same plan.

Another important point is to keep the system in good condition, and to see that the bowels are not constipated nor exceedingly relaxed, Another great prerequisite to prevention is good water.

If patients would only observe the usual laws of health, and avoid improper food and liquor, and *especially* taking liquor in excess when the premonitory symptoms are upon them, I believe that cholera would lose its dread. Great dram-drinkers afford a large field for cholera subjects.

Dr. Bailhache stated that although the vessel at the Breakwater quarantine had been removed, the hospital had been open all winter. On June 1, there will be placed on duty at this point a quarantine boat for boarding purposes. In order to make the quarantine effective, it will be necessary to have the pilots directed to bring all vessels to anchor during the night, so that they can be examined in the morning, for it is almost impossible to run the station day and night. While it was desirable to take these precautions, he agreed with Dr. Formad in thinking that it was very improbable that cholera would visit this country this year.

Dr. E. O. Shakespeare did not agree with those who were disposed to make light of the danger to which this country may be exposed from the invasion of cholera. It is not necessary to have cholera prevail in the northern countries of Europe to have it come to this country. There are two, perhaps three, instances, in which the infection came rapidly from the Mediterranean. The epidemic of 1865 started at Mecca, only nine months before its arrival in this country, in New Orleans, and avoided England entirely. There are two occasions in which the disease entered New Orleans from the West Indies, where it was not known to prevail.

There is, at the present time, a cholera epidemic in Spain, although the attempt has been made to conceal that fact. He did not think that a false alarm was created by insisting on preventive measures at a time when preventive measures can only be efficient, that is, before the invasion of cholera.

The lecturer had recommended the removal of those still well from the house; he should go further and establish a surveillance upon those removed, for it is well established that those who escape from quarantine may later develop the disease, and serve as sources of infection. There is a difference of opinion in regard to the length of the incubation period of cholera. The reports of the last cholera conference at Berlin bear upon this point. Koch states that in ordinary spring-water, the comma bacillus has been found alive at the end of thirty days; in sewage-water, at the end of seven days; in the contents of privies they have been found dead at the end of twenty-four hours, and from soiled garments germs have been cultivated after four days. Rietch and Nicati, at Marseilles, last summer, found comma bacilli living in the harbor at the end of eighty-one days. In a favorable culture soil, as agar-agar, the bacilli have lived one hundred and forty-four days. If these micro-organisms be the cause of cholera,

this has an important bearing on the length of effectual quarantine.

Dr. H. Hartshorne said that in 1854, he, with other physicians, went to Columbia, Pa., to give voluntary aid during an epidemic of cholera which was prevailing at that place. This town is situated on the Susquehanna river. At that time the weather was very hot, and the river was extremely low. Dead cattle were daily thrown from the railroad trains into the river. Many people received their water supply from the river. His observation of these circumstances led him to suspect that decomposing animal matter was the true promotive cause of cholera. A study of the facts concerning the disease in India, where the Ganges is used as a burying place, and where from the inundations large areas are covered with decaying animal and vegetable matters, had confirmed this conclusion. The facts known to-day have been known for a long time, but they used to be explained from a different standpoint. The standpoint is now that of the germ theory.

He had been much interested in reading the most recently stated views of Pettenkoffer, who holds that cholera is not an endogenous, but an ectogenous disease, and that its great determining causation is connected with locality. Pettenkoffer does not deny, but accepts, the germ theory of its causation, although not the comma bacillus. He holds that cholera is not personally contagious, and this, of course, has an important bearing on the preventive measures to be adopted.

Dr. Hartshorne did not admit the view that there is no occasion at present to consider the question of prevention. The history of cholera shows that there is no certainty about its movements; where it was last summer is no guarantee as to where it will be next summer. When it occurs in western Europe, especially early in the summer, it is likely to come to this country.

In 1866 there was a cholera scare almost as great as now, and our Board of Health was driven to take preventive measures. Although cholera came, and there were 900 deaths from the disease, the total mortality for the year was 300 less than the year before. A mortality of 900 was very small in proportion to the population at that time. The disease is not to be prevented by quarantine, which, indeed, it is impossible to enforce. There are many facts which justify the opinion that the disease is not contagious. The illustration of Dr. Bush, where the almshouse inmates were simply removed across the road and no new cases developed, points in that direction. In the Baltimore almshouse, in 1854, there were seventeen deaths on one side of the house, and not one on the other side. On the former side there was under the windows a cesspool into which the refuse from the dead-house was thrown. Pettenkoffer has shown that in Lyons there has never been a great epidemic, although Lyons is between Marseilles and Paris. In the same way, while cholera was prevailing in Carlisle and in Dumfries, it did not prevail in the intermediate town of Annan.

During a cholera epidemic, there should be houses of refuge for the well. It is inhuman to attempt to remove the sick. If quiet is essential in the early treatment of any disease, it is in cholera. Cholera, Dr. Hartshorne thought, could be stamped out by proper sanitary measures, because it is an ectogenous or extra-somatic disease in its origination, not propagated by personal contagion.

Dr. S. S. Cohen stated that his attention had been called to a pamphlet by Surgeon Jessop of the Indian army, describing an outbreak of cholera in a military camp, situated on elevated ground to leeward of the cholera hospital. After a careful study of all the surroundings, the conclusion was reached by the author, that the morbific elements had been carried to his camp by air blowing from the cholera hospital. It was also stated that all of those affected were individuals who had acquired a personal susceptibility by dietetic errors, especially the habit of eating a certain indigestible compound peculiar to the country. The instance was brought forward simply in connection with the theories of causation and transmission, to which reference had been made.

Dr. Ulrich, of Chester, referred to Dr. Hunt's allusion to personal susceptibility, but nothing would produce personal susceptibility quicker than fear. He thought that in Philadelphia and in the large cities, the popular mind had been drawn so tense with apprehension that it was ready to snap. It was all very well for physicians to talk among themselves and give their experience, but he did not consider it wise to fill the press with cholera alarms. . . . While the influence of the mind is potent for evil, it is also powerful for good. He cited one instance where cholera had broken out on a negro plantation, the well individuals were removed with much ceremony and with the positive assurance that the physician could prevent the disease. They were taken to a woods, without tents, and with only one blanket apiece. No case of cholera developed among them. . . . The public mind should be kept in a condition of as little apprehension as possible.

Dr. Blackwood said that he considered the main thing to be prevention. The practice of his preceptor, in a case of cholera, was to have the stools disinfected at once by the use of chloride of zinc, and the clothing and bedding which was soiled burnt. He adopted the same measures in the epidemic of 1866, and where the instructions were carried out the disease rarely spread beyond the first case. Even if Europe were ravaged from one end to the other, he thought that would be no reason why we should have it in this country. If the discharges and clothing, when the disease breaks out in a vessel, were thrown overboard, he thought cholera could not be brought to this country. There should be careful examination of passengers before starting, and careful supervision during the voyage. In a city like this it would be almost impossible to remove the well from the sick, while to remove the sick would be barbarous.

Dr. Gauntt, of Burlington, N. J., said that he was unwilling to ammit that nothing more was known of the cause of cholera than in 1849, when the most eminent pathologists declared that the causes of epidemic cholera and pestilential diseases are among those whose origin and principle is not given to man to comprehend. "That all was mysterious and invisible, all produced by powers whose *effects* alone are revealed to us."

The conservatism of the physicians of Philadelphia, which he so much admired, would scarcely admit the teachings of that date—that the appearance and disappearance of cholera coincided with violent storms, and while cholera prevailed electricity was retained with difficulty; that the power of loadstone was reduced from 80 to 14 pounds, the electric telegraph remained inactive, and that magnetism was almost neutralized; the only sure principles that we then received were that cholera was caused by a disturbance of the equilibrium between terrestral magnetism and the electric state of living bodies.

Pasteur teaches, by his investigations, that death is the result of life in excess, and reveals facts showing that the diseases he has chosen to find a cause for have been the result of a living specific organism, whose destructive power is only controlled by the exhaustion of the soil upon which it depends for its development and reproduction.

If there be a microbe-anthrax for splenic fever, tuberculosis, swine-cholera, chicken-cholera, small-pox, and others, why not for epidemic cholera? If it be not the comma-bacillus of Koch, it must be some other bacillus, whose life is governed by the same immutable law, and whose living principle is a microscopical exotic plant that is capable of reproducing itself in any locality that favors the growth of our indigenous bacilli, called mould, mildew, must, etc., and in such places as other epidemic plants find most congenial. Localities do not produce epidemics; what is called filth, by the aid of darkness, heat, and dampness, offers a congenial soil for this class of plants, and when not preoccupied by the natives, offers a rich soil for the exotic, be it small-pox, diphtheria, yellow fever, or cholera.

From such places the contagium is carried and spread upon all the articles of food and drink, most, of course, in the immediate vicinity, but everywhere, the grocer, the butcher, the baker, and the visitor, is a common carrier of a prevailing disease.

He favored the publication of discussions upon medical subjects in the secular press, and did not believe that the influence of fear could produce any disease.

He said that the cholera bacillus pervaded the air and caused illness by being taken into the stomach with food, and to insure safety after the disease was introduced to any community, the board of health should direct that no person shall eat anything that had not been recently cooked or subjected to a very high temperature, or drink anything that had not been recently boiled.

He was of the opinion that water-pollution endemics, called typhoid fever, of so frequent occurrence, could be speedily arrested by preventing the use of drinking-water until it had been thoroughly boiled, and that Schuylkill water should never be used for that purpose that had not been exposed to a temperature of 212° F., which would effectually destroy the bacilli of typhoid and malarial fevers that abound in that river.

Dr. Gross, of Camden, had expected to hear some reference made to the medical prophylaxis of cholera by the use of sulphuric acid or water acidulated with sulphuric acid, and used for drinking purposes, instead of ordinary water, the strength of which can be modified by the presence or absence of any diarrhœic phenomena. Dr. Roland Curtin, who had charge of the asylum inmates of the Philadelphia almshouse grounds in 1866, fully demonstrated the value of this prophylaxis, "in its use for drinking purposes," and demonstrated its utility by an entire absence of cholera—or, at least, fatal cholera—among his special charges; whereas in the other departments, upon the same ground, there were numerous fatal cases of cholera.

Dr. Shakespeare said, in regard to the influence of fear, if there was one thing settled about cholera, it was that it is a specific infectious disease. No matter what contributing causes may be present, there must be added to these the one specific cause of the disease before there will be cholera. Fear as a cause of disease has, from the time of Adam, been associated with every disease which has attacked man. Every one admits that the state of the digestive apparatus has much to do with the susceptibility to cholera. The disinfectant and destructive power of the healthy gastric juice is a protective against the effects of the specific cause of cholera. Fear may induce such a condition of the digestive tract as will favor the multiplication and activity of the specific cause of the disease, but to assert that it is a cause of cholera is nothing less than ridiculous.

It has been said that the discussion of this subject should be kept to ourselves, and not allowed to reach the people, and that we should attempt to secure the legislation which is necessary to bring about these preventive measures in a meek and quiet manner, and with bated breath. Every one knows that the only way for raising sufficient money for equipping sanitary departments can be obtained, is by arousing public sentiment; and this can only be done by the spread of information among the people, through the far-reaching secular press.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

(*Concluded from page* 68.)

Osteo-myelitis of the Femur.

Presented by Dr. DeF. Willard.

E. H., aged forty, female, has had trouble with left femur for six years; sinuses forming from time to time and healing after many months' discharge. On admission to hospital, an opening two and a half inches in length and one-half inch in width was found upon the inside of the thigh at the lower third. The bone was thickened to twice its normal size nearly to the trochanters; many cicatrices exist at various points on the thigh. The knee-joint is not swollen or painful, but the foot can only be moved through 40° of the arc of a circle. The discharge from the opening is thin, yellow, and very offensive, but not excessive in amount. This sinus has been open for two years. The patient can walk, but is unable to work, and suffers considerable pain. Injections of solution of chloride of zinc corrected the fetor, and as the former sinuses had healed, it was decided not to amputate, although this operation was carefully considered. The opening was accordingly enlarged, and as no sequestrum was found, but the cancellous tissue was much

softened, it was gouged and a counter-opening was made by boring through the outer shell of the condyle, a drainage tube being afterwards inserted. The wound was thoroughly disinfected, and immediately closed with dry sublimate dressings. The cotton used had been prepared with a solution of the corrosive chloride, 1 pt. to 500 instead of 1 to 1000, as was Dr. Willard's ordinary custom. On the second day, the temperature rose to 101° F.; vomiting was quite constant, and accompanied by great tenesmus and the frequent passage of bloody mucus. Upon opening the wound, it was found that the dressings had vesicated the skin for some distance about the wound. Recognizing the symptoms as probably due to the chloride, iodoform dressings were substituted, with carbolized oil. On the fourth day, possibly by infection from a most virulent and fatal case of erysipelas, a chill occurred, followed by fever, with a temperature of 104⅘° F., and upon opening the dressings, an erysipelatous inflammation was found extending from the toes to the groin. The diarrhœa and vomiting had ceased. At 8 a. m. the next day, under quinine and kairin, the temperature was 98°, but in the afternoon, after a chill, it rose to 103° with a pulse of 160, and death took place on the sixth day after operation. On examination, the femur, from three inches below the trochanters to the condyles, was found enlarged to twice its natural size, the outer shell being firm, but the entire internal structure showing marked osteo-myelitic changes. The articular cartilage of the femur was intact, but a ledge of osteophytes prevented anything more than the limited motion of the knee above-mentioned. There was no sloughing of the wound, and the discharge was odorless. Had amputation at the hip-joint been performed, the result would, probably, have been more fortunate.

Dr. Davis inquired at what part of the limb did the erysipelas start.

Dr. Willard said that the parts being covered he could not say whether the wound was or was not first affected.

Dr. Nancrede referred to the not uncommon occurrence of the rash at a distance from the wound to the previous constitutional and glandular involvement, and said that he thought erysipelas was an eruptive fever, just like scarlatina, etc.

Dr. Parish remarked that he had recently seen a patient whose history bore out Dr. Nancrede's remarks, and where the disease appeared at a still more remote point. The patient was one of Dr. Sinkler's where Dr. Parish had withdrawn by the aspirator through the vaginal wall three pints of pus from a pelvic abscess. Erysipelas attacked the face, while at no time was the skin over the swelling or the mucous membrane affected. At the same time that the first abscess was opened, another, more deeply situated, had been recognized. To show the dependence of the erysipelas on the local condition, as soon as the second abscess was evacuated through the abdominal wall of another three pints of pus, the erysipelas disappeared like magic, clearly demonstrating to Dr. Parish the interdependence of the two conditions.

Encephaloid Disease of the Stomach.

J. K. Mitchell.

The facts of the case from which the specimen presented to the society was taken are as follows:

J. M., an Irish teamster, aged 63, was admitted to the Episcopal Hospital November 28, 1884. His family history was good, and his own, except that he had always been a drinking man, and had had lead-poisoning four years previously. For two months before admission, he had suffered constant pain in the epigastrium. For a week his abdomen had been swelling, and he had complained of a constant ache in the back. No cardiac murmur could be heard. The resonance of both lungs was generally impaired; breath sounds were absent at both bases for a space about four inches deep. There were percussion flatness and marked ægopheny over the same extent of surface. A general atheroma of the vessels was present. His bowels were constipated, his urine very scanty, measuring about eighteen fluid ounces daily, sometimes less, alkaline in reaction, dark-colored, and mal-odorous. Not a trace of albumen could be found after repeated examinations by picric acid, Heller's test, or heat. After several trials, Dr. Lewis, in whose charge the patient was, found pale hyaline casts, containing pus-cells, and made the sketch of them which I have here.

Basham's mixture, digitalis, occasional diaphoresis produced by means of pilocarpin, elaterium to evacuate the bowels, and liquid diet, made up the treatment. The man would take no solid food, but drank large quantities of milk. The œdema lessened for a time, but re commenced at the end of six weeks, and about the same time he began to complain that everything taken into the stomach produced a painful sense of fullness. Nevertheless, he continued to take from three to four quarts of milk daily. A portion of this was given to him pancreatized, and the feeling of distension was thus for a time relieved. At the end of January he had a severe and obstinate seizure of diarrhœa, and failed rapidly.

Autopsy Fourteen Hours After Death.—Frame emaciated, belly greatly distended, right leg œdematous. On opening the abdomen the omentum was found very hard, much thickened, and quite white, and covered with small pale yellow nodules closely packed together; the whole was tightly adherent to the neighboring structures, so that to move it moved both stomach and intestines. The liver was small and pale, but of natural consistence and appearance on section. The gall-bladder was firmly fastened by adhesions to the liver and to the intestines. Both kidneys were small, very little congested, the capsules easily stripped off, and except that in each were one or two small cysts filled with clear watery fluid, showed no signs of disease. The abdominal cavity contained about sixteen pints of clear yellow fluid. The heart was small, its cavities were filled with little red and white clots, and the valves were all perfectly competent. The lungs were much congested at the bases, and somewhat compressed by the abdominal distension, but had no other evidence of disease.

The stomach, which I here present to you, was small, very hard to the touch, and externally felt rough. On opening it, nearly the whole internal surface, but more especially the posterior wall, about its middle, was found covered with masses

of hard elevated nodules, grayish-red or black on their tops, with diffuse inflammation surrounding the base of each. Among these some were softer than others, and in some the most elevated portion was ulcerated. The walls of the organ were very hard and firm.

The appearance suggested to me a diffuse carcinoma, and on making some sections and examining them microscopically, I was still more inclined to this view. Dr. F. P. Henry, who also examined some sections, found no evidences of cancer, and Dr. J. H. C. Simes, after also examining specimens thought cancer possible but doubtful.

The pyloric orifice does not appear closed at all, but there is a slightly increased induration about it which may prove to be the scirrhus from which the formation on the posterior walls has spread. The growth had all the macroscopical appearance of encephaloid, and occupied the more usual seat of that disease. The thickening of the walls of the stomach may too be due to that hypertrophy of the muscular coats which not uncommonly occurs when an extended growth of carcinoma exists, and adhesions such as I have described also are frequently found in such a condition.

I should like to submit the specimen for the consideration of the committee on morbid growths, who will, I hope, determine its character.

May 14, 1885.

Drs. Henry and Simes having both examined sections microscopically, were unable to detect anything beyond atrophy of the glandular elements with hyperplasia of the connective tissue.

Dr. O'Hara asked if there had been any symptoms of stomach disease.

Dr. Mitchell replied that there had been almost complete absence of stomach spmptoms; the patient complained of a feeling of distension after taking food, but vomiting had never occurred except after the administration of jaborandi.

Dr. W. A. Edwards inquired whether the nodular omental masses had been examined microscopically, and also what was the condition of the other glands throughout the body, as a knowledge of the condition of these structures would throw some light on the case.

Dr. Osler said that in the absence of evidence of carcinoma he thought that the case must be referred to general cirrhosis of the stomach, of which he had seen two cases; one involving the stomach alone, the other both that organ with the cæcum and a small portion of the colon. In both cases the actual presence of carcinoma could be excluded. He thought Dr. Mitchell's case was possibly one of this rare disease characterized by atrophy of the glands and increase of the fibrous stroma. He thought, however, that the omental nodules should be examined, for it is well known that in some cases of carcinoma of the stomach, with much thickening around the pylorus, etc., we could only be certain of the diagnosis by examination of the secondary nodules. In his cases there had been no adhesions of the stomach to other viscera.

Dr. Mitchell said that he was unacquainted with cirrhosis of the stomach, but that if his specimen were regarded as one of that disease, it left unaccounted for the actual or impending ulceration of one-third of the posterior wall of the stomach.

Dr. De Schweinitz presented for Dr. Randall a specimen of mastoid disease and meningitis, the notes of which will be published elsewhere.

Dr. E. C. Shakespeare made an interesting report of the facts arrived at by Dr. French and himself during their investigations of the recent typhoid outbreak at Plymouth, Pa.

EDITORIAL DEPARTMENT.

PERISCOPE.

Two Cases of Sudden and Extreme Loss of Hearing Relieved by Pilocarpine.

Dr. Thomas Barr thus writes in the *Brit. Med. Jour.*, June 13, 1885:

Disease of the nervous apparatus of the ear is usually so hopeless, and so little affected by remedies, that cases, such as the following, in which favorable results are obtained by treatment, seem worthy of being brought before the profession.

Case 1. J. M., a ship-steward, aged twenty-two, presented himself for treatment at the Glasgow Ear Hospital, on August 25, 1884, suffering from almost total deafness. He was a man of pale and unhealthy aspect. Six months before, he contracted syphilis, followed by secondary symptoms; for which, however, he was successfully treated. He was also somewhat addicted to alcoholic indulgence. One of his sisters suffered from phthisis pulmonalis, but the other members of a pretty large family were quite healthy.

Inquiry elicited from him the following account of the origin and course of the disease. About six weeks previously, while crossing the Atlantic on the voyage out to Montreal, he was seized with great nausea, vomiting, and severe giddiness. Accustomed to sea-life, he knew that he was not liable in the least to sea-sickness. By the time the ship arrived at Montreal, the sickness had passed away, and the giddiness had become much less. On the afternoon of his arrival, however, while walking in one of the streets of Montreal, the weather being extremely hot, he was suddenly seized with giddiness so extreme that he staggered and fell to the ground, without losing consciousness. After a short time, he recovered sufficiently to make his way, with assistance, to the ship. He was put in bed, and the surgeon of the ship prescribed some form of pills.

Up till this time, his hearing was unaffected; and, indeed, at no time during his past life had there been, to his knowledge, any dullness or other disturbance of the hearing on either side. On the following morning, however, he awoke

from sleep finding that his left ear was apparently totally deaf. As he lay with the right side of his head on the pillow, he could not hear what was said by a man speaking close beside him. But now a loud noise, like the rush of water, was constantly present in the deaf ear, as well as through the head. Towards night, the hearing of the opposite or right ear seemed also to be passing away, and next morning found him absolutely deaf on both sides, so that the loud shouting of his mates close to his head was by him quite unperceived. The extreme giddiness continued, and the loud rushing noise filled his head.

During the whole of the voyage back to Liverpool, he lay in bed in a condition of great dizziness, nausea, and total deafness. When he attempted to walk, his movements were like those of a drunken man; he kept in a straight line for a few steps, then reeled from side to side. Up till his arrival in Liverpool, there had been little, if any, pain in his head; but, while in the steamer from Liverpool to Glasgow, he became affected with severe pain in the back of his head, and very especially in the region behind his ears.

In Glasgow he was placed under the care of Dr. Halket, who shaved the head and applied a cantharides plaster on the surface behind each ear. These were repeated two or three nights afterwards. There was also prescribed by Dr. Halket a mixture containing iodide of potassium chiefly, with good effect, "clearing the head and helping the stomach," as the patient expressed it.

One morning, shortly after his arrival in Glasgow, when he awoke from sleep he experienced a sensation of stiffness in one cheek; and on examination, with the aid of a mirror, he found his face drawn to the left side. The odd appearance which he presented, with shaven head and twisted face, constrained him, even in his sad condition, to smile; this facial movement rendered, of course, the twisted appearance still more striking. In attempting to drink tea or water, the liquid tended to trickle out of his mouth. This facial paralysis of the right side was of short duration, passing away in the course of the same evening.

About this stage of the illness a consulting physician saw the patient, and expressed an unfavorable prognosis. His state, nevertheless, began to improve. Under treatment by iodide of potassium the pain in the head diminished, and the giddiness became much less, although some tendency to stagger still continued. The deafness, however, remained unaltered, and as soon as it was practicable, about seven weeks after the beginning of the illness, Dr. Halket sent him to the Ear Hospital for treatment.

On admission, I found his hearing by both aerial and osseous conduction, almost quite abolished. Words spoken very loudly into his ears could not be understood by him. In the right ear, however, the voice was heard, although the individual words could not be distinguished. He was unable to hear the loud tick of a watch on either side, pressed firmly on the auricle or on the bones of the head. The sound of a vibrating tuning fork applied to the bones of the head was also unperceived. Objective examination of the outer and middle ears yielded negative results; on both sides the tympanic membranes presented quite a normal appearance, while the Eustachian tubes were permeable. He did not now complain of the subjective sounds. The vertigo was much less than at an earlier stage of the illness; but there was still a disposition to stagger in walking. The pain in the head was at times quite absent, but now and then it returned in severe paroxysms.

The digestive functions seemed to be much disturbed; the tongue was thickly coated with a yellowish-brown fur, the bowels were persistently constipated, while an extremely foul odor was exhaled by the breath.

He was admitted to the indoor department of the hospital, and at once treated by pilocarpine injections. One of Wyeth's tablets, containing a third of a grain of the drug, was dissolved in six minims of water, and injected underneath the skin of the shoulder every second day for six days, and then every third day for nine days. Copious perspiration followed every application of the remedy. The first produced very considerable sickness and vomiting; on every subsequent occasion there was some nausea excited, but it was much less than after the first. The patient always remained in bed for a few hours after the use of the remedy.

Improvement in the hearing almost immediately manifested itself. A day or so after the first injection the patient noticed some improvement in the right ear, and this improvement seemed to go on gradually almost day by day. In three weeks after admission, he could hear and understand, with the right ear, conversation in a voice only slightly elevated above ordinary speech. In other respects also his condition improved. He soon afterwards resumed his occupation of steward on board a steamer.

On April 18, 1885, about nine months after the seizure, his state was as follows: On the right side a watch whose normal hearing distance is forty inches, was heard eight inches. On the left it was not heard even on pressure. This does not, however, truly represent his power of hearing speech, which was so good that persons conversing with him did not detect any dullness of hearing. A vibrating tuning fork applied to the middle line of the head was heard better in the right ear.

There were no subjective sounds in the ear or head. The tendency to stagger, which had continued for a considerable time, while in the dark, had passed completely away. The complexion was much healthier looking, the tongue was clean, and the breath was free from the foul odor.

Case 2. R. McG., a laborer, aged 54, was admitted to the Ear Hospital on February 20, 1885. He stated that he had been suddenly affected a fortnight before admission with total deafness while in the act of stooping at his work. He had been out of work for some months, and this sudden loss of hearing occurred just on the morning of his return to work. His bodily health had suffered from the poverty due to the enforced idleness, while his mental condition was depressed, owing to the conduct of a reprobate son. No hereditary tendency to ear-disease, and no syphilitic origin, could be traced. The shock of deafness, he said, was signalized by a sensation as if a pistol had been discharged in the interior of his head, and immediately afterwards he ceased to hear the noises in the ship-building yard where

he was employed, or the voices of the workmen. This was followed by severe pain affecting the whole head, but especially the vertex, and by a sensation in his right ear, "just as if a clock were working inside." There was also slight giddiness.

On admission, it was found that a watch with a loud tick could not be heard on pressure in either ear. The voice could not be heard, although loudly spoken into the right ear; in the left it was heard, but only partially understood. Osseous conduction by the tuning-fork was faint, and the duration of the perception was short. Objective examination of the ear showed a small oval calcareous patch, evidently of long standing, on each tympanic membrane, behind the handle of the malleus. These were probably the results of old catarrhal affections in the middle ears, and had no connection with this attack. Inflation of the middle ears had no effect upon the deafness. A cantharides plaster was first applied behind each ear, without, however, yielding any good result.

Subcutaneous injections of a solution of pilocarpine were then employed. The solution contained at first only one-twelfth of a grain of the pilocarpine; but it was increased, after three or four injections, to one-third of a grain. In the weaker form, they were employed daily; but the stronger solutions were only used every third day. In all, eight injections were employed. The patient remained in bed for six hours after each injection, and free diaphoresis always followed. Slight sickness was excited by the strong solutions. Improvement in the hearing of speech was observed when two injections had been used, and after that there was gradual but steady improvement in the hearing, with disappearance of the subjective sounds.

On April 13, 1885, two months after the seizure, the condition was as follows: The tick of a watch heard, in normal hearing, forty inches from the ear, was heard eight inches on the right side and one inch on the left. Conversation in an ordinary tone of voice was understood without any difficulty. The osseous conduction of sound by the tuning-fork was heard rather better than the aerial—a circumstance which was probably due to the existence of the old catarrhal affection of the middle ear. The subjective sound had completely disappeared.

Observations.—There can be little doubt that, in the two cases here described, the seat of the mischief was in the nervous apparatus of hearing. It is, however, not possible to determine with certainty in what part of the auditory nerve the lesion existed—whether in its roots in the brain, in its stem, or in its complex terminal expansion in the labyrinth.

In the first case, which was clearly due to syphilis, the gravity of the symptoms seems to indicate that the mischief was intracranial. The premonitory symptoms of nausea and vomiting, the pronounced vertigo and staggering, the severe pain in the back of the head, and the temporary affection of the facial nerve, seem to point to the auditory centres in the cerebellum as the probable seat of syphilitic exudation. On the other hand, in the second case, the lesion was probably labyrinthine and apoplectiform in character (apoplectiform deafness of Knapp), and of the nature of rupture of a small vessel simultaneously in both labyrinths, excited by the stooping posture, and predisposed by a generally enfeebled state of the system. The absence of marked vertigo is a somewhat noteworthy peculiarity of this case, and suggests that the lesion was more probably in the cochlea than in the semicircular canals.

When we consider the generally hopeless character of lesions of the nervous structures of the ear, it can hardly be denied that the favorable terminations in both of these cases were due to the action of the pilocarpine. Politzer, who was the first to propose this remedy in ear-disease, believed it to be serviceable chiefly in cases of labyrinthine disease of recent and sudden occurrence, and especially in those of syphilitic origin. My experience, as shown in these two cases, seems to confirm this view of the value of pilocarpine. In several instances of labyrinthine mischief gradually coming on in the course of chronic middle-ear disease, where I have used this remedy, there seemed to be no effect produced. As to the explanation of the therapeutic action of pilocarpine, we can only assume that it has an especial power of stimulating the absorbents in contact with the effused products before these have become organized, and that this resorbent effect has also some connection with its remarkable powers of exciting the cutaneous secretion. It seems to have a more decided action upon the intracranial absorbents; and the vascular and lymphatic supply of the labyrinth is in reality the same as that of the interior of the cranium. If this view of its action be correct, it would be reasonable to employ this method of treatment more generally in cases of cerebral apoplexy.

Recovery of Good Sight, after Twenty Years' Blindness.

Dr. George E. Walker thus writes in the *Lancet*, June 6:

Accustomed as I have been, during some dozen years' practice of the operation, to the great benefits resulting from the severance of adhesions of the iris to the cornea, I confess that the case which I now relate has astonished me not a little.

L. N——, a girl aged nineteen years and three months, was admitted to the School for the Indigent Blind on April 22, 1884. Her right eye showed all the cornea, except a narrow rim round the margin, as one dense leucoma to which the iris was universally adherent. Of course, this was hopeless. The left, in the central lower part, showed a dense leucoma, which shaded off rather abruptly into a fainter one just above, the whole leucoma having a diameter about half that of the cornea. The iris was adherent to the central part of the leucoma, except at the inner side, where a little of the pupillary edge had escaped, so that a very small pin-hole was left; but as it was behind the leucoma and could only be seen sideways, it was not available for vision, and the girl said that she could see no better with the left than with the right eye, nor could she count fingers with either, but had only perception of light.

Thinking that I might give the left eye enough sight to enable her to move about without knocking against chairs and tables, I suggested to her and her father the propriety of treatment; but

when they found out an operation was required, I received a prompt negative. At last the father consented that the girl should please herself, but it was not until November that she asked me to operate on her. On the 22d I attacked the upper part of the adhesion in the way described in the *Lancet* of January 31, p. 197, gaining a considerable increase of pupil. She suffered somewhat from the chloroform, and consented very reluctantly to the second operation, by which, on December 10, the severance of the upper limb was completed. On January 6, I divided the lower limb at one sweep, although it was very broad, and on the 13th I cut the little bit remaining on the outer side. She was so averse to this last operation that I had to pretend an anger which I did not feel, and almost compel her to submit. One would have expected that the great benefit which accrued most markedly after each operation would have made her eager to submit, but the contrary was the case. Her first sensation after admission of light into her eye was one of profound horror. She says now that when she first became conscious of sight, and therefore to some degree of space, her feeling was like that of one who looks over a precipice and fears that he will be impelled to throw himself down, and she, at the time, bitterly repented her consent to be taken out of the darkness which all her life thus far had enshrouded her. By this time, however, the leucoma had cleared up, especially in the upper part, and we found that she had a good-sized pupil, elongated from side to side, the upper, lower, and outer edge ragged from the cuts, whilst the inner presented the normal curve. I had hitherto thought it most probable that the lens had been destroyed, but now I found it existent and transparent, and on testing the eye (January 28) discovered that the long tension of the imprisoned iris has produced a myopia, requiring a 15 D. glass for its correction. The wearing of this speedily caused a change in her state of mind, and she soon ceased to regret her loss of blindness. Under the affectionate tuition of a fellow patient she learned her letters in a day, and to read in a week. Of course this was all the easier from her ability to read with her fingers on Moon's types. Like as occurred in the little boy whose case is described in the *Lancet* of January 31, 1885, a filament of uveal exudation joins the lower edge of the pupil to the cornea, and I shall divide this if I have reason to believe that it keeps up, in any material degree, the over-nutrition of the leucoma. This, however, now deprived of the large blood-supply given to it by the almost universal adherence of the iris, has cleared up greatly, the upper part being almost transparent, and her vision is now (March 2) $\frac{3}{10}$, and she reads pretty easily Jaeger 10, and with some little difficulty Jaeger 8—that is, print about the size of "leading article" type.

The main element of the surprise which I have experienced over this case is the retention of visual acuity by the retina under the twenty years' deprivation of light. I see so many examples to the contrary in the persons who present themselves at the Blind School—as, for example, in cases of neglected cataract, as well as in the more familiar instance of squint, which produces the amblyopia (ex inopsia of the old writers) that I was not prepared to find that in this girl the retina had preserved its sensitiveness so well; for all the want of acuteness now present may safely be debited to the opalescence of the cornea, which still remains. As this, however, is plainly decreasing, I trust that the eye may further improve. Another interesting fact is that the muscular tissue of the iris shows itself to be quite lively, as it responds promptly both to myotics and mydriatics.

I think now that I have said enough to show that this class of case—a more numerous class, probably, than that of cataract—is susceptible, even in the more formidable instances, of beneficial treatment, and that on the whole we may expect results at least as satisfactory as in other grave diseases of the eye.

Two Cases of Raynaud's Disease.

Before the Clinical Society of London (May 22): Dr. Colcott Fox brought two adults affected with this disorder, and read notes on the cases. A woman, æt. 41, of extremely nervous temperament, dated the commencement of the disorder from ten years back, but though this was the period when her attention was attracted by her pain, it is probable that she suffered from slight attacks for some years previously. In the earlier stages all her fingers continually went "like white wax." This condition of recurrent local syncope gradually gave place to local asphyxia, and the feet became involved. The fingers gradually lapsed into a state of chronic asphyxia, which was intensified by frequent attacks of more severity, often leading to "blood blisters and ulceration." The nutrition of the phalanges has suffered greatly, so that her hands are crippled, the fingers are fusiform in shape, livid, shiny, and withered, the nails variously distorted, and the end phalanges much atrophied and almost immovable. The nose and ears are affected to some extent on exposure. Cold and nerve shocks are ready exciting influences. The second case was that of a man, æt. 51, and was of considerable interest, from the fact that, like one of Raynaud's cases, he suffered from diabetes. His hands were not deformed, but he had suffered for several years from "dead fingers." He sought Dr. Fox's advice for symmetrical gangrenous patches on the skin, which recurred, and later for an attack of asphyxgia of one great toe and lower third of the inner side of the leg, and then it was found that he had been attacked in a similar manner, though more severely, in the other toe, and on another occasion blood blisters had formed beneath the ends of his toes. Dr. Fox concluded his paper by giving a reference to some cases which have been recorded as scleroderma of the extremities. A woman with the latter disease was shown to illustrate the difference between it and Raynaud's symmetrical gangrene of the extremities.

Dr. O'Connor would like to ask Dr. Fox if there was any history of phthisis or bloody urine? Last year, before the Pathological Society, he had shown a case of symmetrical gangrene. It was not entirely uncomplicated, but associated with thoracic tumors. He had tried nitro-glycerine in an attack which corresponded with Dr. Fox's case,

and in which the symptoms were materially lessened.

Mr. Harrison Cripps thought the pathology of these cases was somewhat obscure. He was always forcibly reminded of frost-bite and senile gangrene. The former was a local starvation of a part, and the latter wholly due to constitutional causes. Raynaud's disease stood half-way between the two conditions. A tree may carry on its circulation except in the extreme branches, and he thought this was a fair simile. The parts should, he thought, be well wrapt up, so as to guard against the changes in the atmosphere.

Dr. Barlow would like to make a few remarks upon the therapeutic aspects of the matter. He recommended the continuous current. He had determined to try this in some cases. In a very severe case that could hardly walk, and had suffered for two years, he began by treating with the constant current, placing one pole down the spine and the other upon one of the extremities. This did not prove very effectual, so he applied both poles to the affected parts. He galvanized for about twenty minutes every two days. Marked benefit resulted. The patient was able to go about his work, and the result has been permanent. He instructed him to shampoo his feet with oil. In the acute paroxysmal attacks during the intervals the patients are perfectly well, but in cold weather there was always a liability to attacks. The attacks lasted on an average a couple of hours. There was intense pain, the patient could hardly be kept still, the feet were quite black, and there seemed impending gangrene. In one attack after ten minutes he applied the constant current for half an hour. Then the hand became quite right; the other hand remained black for a longer time. He had tried nitrite of amyl in capsules, since by this remedy the arterioles were relaxed, and it had exerted physiological effects. If it had been administered earlier it might have succeeded better. The constant current, if used at all, should be employed every day, with the addition of vigorous shampooing.

Mr. Bryant said that he would like Dr. Barlow's remarks to be embodied as a communication to the Society. This had been done before.

Dr. Fox, in reply, said there was no hemoglobinuria; the agonizing pain felt is the attack is going off. The gangrene unquestionably was not due to diabetes. He had tried the constant current with great benefit.

Abscess of the Brain.

Dr. W. F. Westmoreland thus writes in the *Atlanta Med. and Surg. Jour.*, July, 1885:

W. C., age 26 years, presented himself to the clinic, October 13, suffering with severe pain in the head, well-marked stupor, and disposition to coma. He gives the following history: Four years ago, in a fight, he was struck on the head with a hoe. The blow fractured his skull, and rendered him senseless at the time, and for two weeks he was unconscious. He says that after that time he began to grow better, and was soon able to attend to his duties, but that the wound made with the hoe never healed. He says there has been a constant discharge from the wound all the time, but there has been very little pain until recently. It is a well-known fact, gentlemen, that abscess of the brain sometimes comes on a considerable time after injury. Horner mentions an instance where there was an interval of nearly twelve months from the infliction of the violence until the abscesss appeared. Sir Everhard Home mentions a case where nineteen months elapsed. There are examples to be found in Gross' Surgery where three years elapsed from the time of injury until the abscess appeared. In this case it is a little over four years since the injury was inflicted, and he has been suffering for a few days only with well-marked symptoms of abscess of the brain. There is one thing that may possibly influence this trouble. The patient had syphilis, and was treated for it before the reception of the injury to the head, and that may possibly influence the trouble and prevent the healing. There may be a piece of necrosed bone that has kept the discharge up. We will cut down upon the bone, and then we can determine whether we have necrosis or not. We simply make the existing opening in the scalp larger, and we find an opening in the cranium that has existed from the time of injury. A probe is now introduced into the opening and carried towards the centre of the brain, following a fistulous track: now with the probe introduced to the depth of four inches, you will notice that the pus flows freely. The treatment will consist in keeping the wound in the scalp open, and keeping the abscess well drained, and in consequence of the old syphilitic trouble, we will direct for him thirty grains of iodide of potash, to be given after each meal. The potash should be given largely diluted with water.

October 17. The patient is suffering to-day very greatly as the result of a closure of the scalp wound and a want of free drainage. We reopen the wound and make it larger, and direct that the wound be kept dilated with an elm tent.

October 24. Patient doing very well; abscess discharging freely and the patient free from pain; treatment continued. From October 24 to November 28, the discharge kept up; the patient was kept on same treatment.

November 28. Discharge has almost ceased; the probe can be inserted only three inches, showing a filling up of the cavity at least one inch.

December 12. The patient has been improving constantly, and the cavity in the brain is gradually filling; it measures only two and a quarter inches to-day.

January 12. Patient says he is feeling very well. He is wonderfully improved; is gaining flesh daily. The cavity has filled so much that the probe will only pass in one and a half inches. There is still a slight discharge.

February 6. Patient says he has felt perfectly well until a day or two ago, when some slight pain began at the old sore. The wound has healed entirely. We make an opening through the scalp to relieve this pain, and find a slight amount of pus tinged with blood. The probe that once could be introduced four inches into the brain will not pass in at all. We have every reason to believe that the patient will soon be well.

February 20. To-day we find the wound entirely

healed, with no pain at all. Every symptom has subsided. There has not been the slightest trouble since his last appearance; we therefore dismiss the patient as cured.

Syphylitic Hepatitis.

Dr. Robert S. Young thus writes in the *North Carolina Med. Jour.*, June, 1885:

On June 15, 1884, I was called to see a ten-year-old white girl, suffering from abdominal enlargement and dyspepsia, with the following history: Both parents living and in good health. The patient has been remarkably free from the ordinary diseases of childhood, and seemed to enjoy better than the average health until about one year ago. She then began ailing, without being actually sick. Her appetite failed; she lost flesh: had some eructations; her bowels moved sluggishly, and a general lassitude came over her. She was treated for scrofula, dyspepsia, and worms; tried a change of climate and the numerous mineral springs; nor did she escape the trial of every "patent medicine" which was recommended and urged by her many friends; she was kept from school and placed upon all kinds of diet, all to no good. The abdomen began to swell, and continued from day to day to grow larger; her strength completely broke down at last, and she could no longer leave her bed. This was the history of the case up to the time of my first visit. When I saw the little girl I at once noticed her cachectic appearance; her wrinkled face; the dull, listless expression of her sunken eyes; the peculiar dirty-yellowish hue of her skin; her emaciated body, and the prematurely old expression of countenance so often met with in children suffering from hereditary marasmus. The organs of the chest were normal. The abdomen was greatly enlarged by serous effusion. The fullness of the superficial abdominal veins denoted a congestion of the portal circulation. The great amount of the effusion and the tympanites above, effectually prevented me from determining the size of the liver with any degree of accuracy. Her tongue was pale, flabby, and covered by a whitish coat, and was indented by her teeth, which presented the characteristic notching of the central incisors first described by J. Hutchinson, which is of great significance in the diagnosis of retarded hereditary syphilis.

Remembering that ascites is rare in children, and that, when it happens, it is generally caused by tubercular peritonitis, or by cancer of one of the abdominal viscera, I made, more by exclusion than anything else, and by reflecting upon the failure of all kind of treatment tried so far, the general diagnosis of retarded hereditary syphilis, and the special diagnosis of syphilitic hepatitis. If success of treatment can verify a diagnosis, then mine was correct. Paracentesis was performed, the effusion and tympanites seriously threatening a fatal interference with the action of the heart, and nearly a gallon of a slightly opaque, yellowish fluid, containing a large percentage of albumen, was slowly withdrawn.

Mercurial inunction into the abdominal walls, and gradually increasing doses of the iodide of potassium, formed the treatment, and I had the gratification of seeing the child in good health by August 10, a little less than three weeks after beginning these therapeutic measures.

Immediately after the performance of paracentesis the liver was found to extend down to within an inch of the ilium; the organ was soft, tender, and its margins smooth and even. The spleen was also slightly enlarged. The fluid never accumulated again. The patient was afterwards placed upon a tonic treatment, and when discharged the liver still extended two inches below its normal position.

Several months later (December 6) I saw her again; she seemed in excellent health, and there was no trace left of her former illness, except the notches in her teeth. The liver and spleen promptly returned to their natural size. The urine had never contained albumen in abnormal quantities, but for a short time there was present therein a trace of the coloring matter of the bile.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The value of electricity in various reflex neuroses is illustrated by a number of clinical cases in a communication reprinted from the *Virginia Medical Monthly*, by Dr. J. J. Caldwell, of Baltimore, Md.

——A discussion of Vitiligo, by Dr. R. H. Reed, of Mansfield, Ohio, has been reprinted from the Cincinnati *Lancet and Clinic*. It is a careful summary.

——The annual announcement of the department of the University of Pennsylvania devoted to biology will have a special interest for scientific men. The director is Dr. Joseph Leidy, than whom a more competent master of the subject the world does not offer.

——The announcements of the medical departments of the Jefferson Medical College and University of Pennsylvania for 1885–6 have been issued, and show both those institutions in a flourishing condition.

——Dr. Wm. C. Wile, of Sandy Hook, Conn., has reprinted, with illustrations, a number of surgical cases which will be read with interest by those studying that branch.

——We have received from the Illustrated Medical Journal Co., of Detroit, Michigan, several sets of their Perforated, Adhesive Medical Journal Labels. The list includes besides the journals of the United States that are devoted to Medicine, Pharmacy and Hygiene, those of the Provinces of Canada, as well. Complete sets will be mailed postpaid for fifty cents on addressing the publishers above named. They are just what every physician needs for addressing his Reprints for journal notice, and Medical Colleges for addressing their Announcements for a similar purpose.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

TREATMENT OF DYSENTERY AND SUMMER COMPLAINT.

Dr. Geubin, in Russia, had considerable experience in the treatment of cases of dysentery and of cholera morbus. His results have been so uniformly good that the Medical Society of Kaluga requested him to communicate to them his mode of treatment. The report is published in the *Wratsch*, 12, '84.

Instead of the usual procedure of combining purgatives with opium, G. administers castor oil followed by oleum terebinthinæ, which latter he gives in doses varying from that of ten drops to such of a fluiddrachm. In almost every case thus treated an amelioration of the symptoms almost invariably at once set in, though some cases later suffered from disagreeable secondary effects, viz., affections of the kidneys, due to the large doses of oil of turpentine. In the adoption of G.'s treatment, caution is therefore necessary.

Probably the best treatment thus far known in dysentery consists first in the administration of a large dose of castor oil, then of repeated doses of ipecacuanha and opium—both in rather decided doses—and finally in the injection of large quantities of water containing chloride of sodium and in the, if possible, local application of nitrate of silver. If the ulcer can be seen, the solid stick is the best; if too high up, solutions are better, and these may be made of considerable strength without causing disturbance.

In the summer complaint, as so frequent amongst children in our own country, we generally have found the following treatment to answer best:

The child must receive no nourishment, with the exception of small quantities of rice-water, for the first twenty-four hours. At night, before going to bed, the child is placed in a warm bath, and afterwards wrapped up in blankets. When the perspiration, thus caused, has ceased, the child is carefully dried, dressed in its warmed night-clothing, and put to bed, the linen of which, as well as that of the child, must be changed twice daily, or oftener. In the early morning the child is taken to some sheltered, cool place, either in the country, or if possible in a boat on the

water, or an island in the middle of a large river, or, best of all, kept at the seashore. Internally, small doses of sulphite of sodium (not enough to cause in a healthy child diarrhœa), and of aqua chlorine are administered, and if the little patient has been nourished with its mother's milk the result will always be favorable, while in children artificially fed, the main necessity consists in their being at once removed to the country, or, still better, to the seashore. If such children, who have been brought up by aid of the bottle, are left to remain during the hot season, while suffering from cholera infantum, in the city, our experience has been that most of them will die, notwithstanding the most careful treatment. Many cases do not recover from want of pure air, and of cleanliness, this being the reason of the many deaths amongst the children of the poor.

A DANGEROUS ACCIDENT.

Some time since, Dr. J. C. Biddle, the Surgeon-in-chief of the Pennsylvania State Hospital for Injured Miners, in Ashland, Pa., performed the operation for resection of the head of the femur. The operation had become necessary in consequence of a badly-cured fracture of the surgical neck, which had been of nearly a year's standing and received no correct treatment until the patient came under Dr. Biddle's charge. An immense quantity of pus had accumulated. After Dr. Biddle had laid bare the bone, he took hold of a large syringe containing a solution of corrosive sublimate, and thoroughly cleansed out the cavity. While so doing, he stood in such a position to the patient as to turn his right side to him, while his assistant was looking at the wound more with his left eye. There was a good deal of splashing of pus at the time.

Three days later, Dr. Biddle's *right* eye suddenly commenced to inflame, and about ten hours after his assistant's *left* eye. As usual with physicians, they did not attend to it in the right way, or rather they neglected what in others Dr. Biddle would have at once rigorously treated. Nearly two weeks later purulent ophthalmia was fully developed; granular lids threatened, and the assistant's other eye commenced to inflame. They hesitated no longer, and, what they ought to have done at the beginning, came to Philadelphia and have visited the most experienced specialists. The cases looked exactly like those due to gonorrhœal infection, but Dr. Biddle was positive that he had no case of blennorrhœa in the hospital for over a year. Besides, the history was too clear, the fact of the right eye in the one and the left eye in the other patient suffering also pointed to the real cause, and lastly, the small period of time intervening between the times of outbreak and the equal period of incubation in both.

For almost two weeks the eyes were under the personal charge of one of our most eminent ophthalmologists. Then they had so greatly improved that Dr. Biddle and his assistants are permitted to return home. If we consider how necessary is the presence of the surgeon-in-chief in such a hospital—Dr. Biddle had once to perform about thirty amputations in one week, not counting all the other grave accidents, many of them too late for such an operation—we can imagine how serious was the loss of the use of his eyes for so long a period to Dr. Biddle, not at all to think of the possible dangers of granular inflammations in the eyelids. As very strong solutions of nitrate of silver had to be used in the treatment, the procedure also was a very painful one; the severe ache generally lasting for three hours after each daily application. For yet some time to come both patients will have to visit Philadelphia once a week to consult the specialists.

These cases are besides of great interest from the fact that there is no case on record where a surgeon had met with such an accident from a non-specific purulent discharge, and for this reason alone they are well worth being added to medical literature. Generally in hospitals, where so many operations are performed, specific cases also are abundant, and if the surgeon had to suffer from such inflammation, he was in the position positively to deny the possibility of a specific infection. But the Ashland Hospital admits *only* accidents, and in this case Dr. Biddle was certain that for over a year no patient in the hospital had

been affected with any disease of this kind. That the solution of corrosive sublimate could not have caused the ophthalmia has long been proven.

Notes and Comments.

Oleate of Manganese.

Dr. Franklin H. Martin thus writes in the *Med. Record*, June 27, 1885:

Since manganese first received notice in this country as a menstrual stimulant, and as a remedy in functional amenorrhœa, menorrhagia, and metrorrhagia, it has been a formidable problem to the minds of therapeutists and pharmacists to get it into an acceptable shape for administration. The permanganate of potash, the original peparation used for experiments and administration in any form, is liable to act as an irritant to the stomach, and is very objectionable to many on that account. It has in many ingenious ways been made into pills, but as these pills must of necessity have for their basis kaolin, or some other inorganic substance, the drug is not satisfactorily observed. The compressed tablets of Wyeth & Brother and others, are objectionable in many cases of irritable stomach, because of the irritating and undiluted drug coming in direct contact witb its mucous membrane. The binoxide of manganese has, on account of its insolubility, proved to be almost inert. On account of the many difficulties of administration, therefore, this valuable drug has not met with the warm reception that is its due. Through a suggestion of Dr. S. S. McArthur, I have succeeded in having an oleate of manganese prepared.

Method of Application.—Of a twenty per cent. solution of the oleate, I should recommend that one drachm be applied to the abdomen of the patient, and its absorption promoted by friction produced by vigorous rubbing of the surface with the palm of the hand or with the fingers. The rubbing should be continued until the oil has entirely disappeared by absorption.

In cases where it is found impracticable to apply it to the abdomen on account of tenderness, it may be applied to the spine or the inner surfaces of the thighs.

In cases of amenorrhœa it should be applied, if possible, every night for a week preceding the expected menstrual period, or at the time the menstruation is due, and until it makes its appearance. In cases of menorrhagia or metrorrhagia it can be applied in smaller quantities every night until the desired effect is produced.

I am very anxious to see the profession give this preparation a good trial, because if there is any great value in this drug, it can only become popular as a remedy in some such unobjectionable form.

The oleate was prepared as follows: A solution of sulphate of manganese was made in distilled water, and to it a solution of sodium oleate was added. On mixing these two solutions gradually and with constant stirring, a precipitate of oleate of manganese resulted. This precipitate upon heating changed to a putty-like mass. This was thoroughly washed several times with warm distilled water, to remove the sodium sulphate, and the resulting putty-like mass was the pure oleate of manganese. This oleate, when dissolved in oleic acid to the required per cent., is ready for use.

Direct Inoculation of the Human Being by Tubercle.

Dr. E. A. Tscherning (*Fortsch. d. Medicin.*, 3, 1885,) reports the following almost unique case:

A healthy female cook, æt. 24, served with a gentleman, who soon died of acute tubercular consumption. While staying with him she one day injured herself on the palmar surface of the first phalanx of the right middle finger by a broken piece of his cuspidor entering her finger. The sputum, which was then in the spittoon, was examined by T., and found to be full of tubercle bacilli in almost their pure culture. About a fortnight after the injury the first symptoms of panaritium developed themselves in the finger. Suppuration did not ensue, but instead of it soon after a nodule of the size of a split pea could be felt in the subcutaneous tissue. An incision was made, and lying between the sheath of the sinew and the skin was found the granulating growth, which was destroyed with the sharp spoon. The wound healed within one week.

A few weeks later patient complained of pain on flexing the finger. The parts then appeared swollen, and at the same time the axillary glands were enlarged, but the lungs apparently healthy. These glands now were removed and the finger amputated below the affected part, and the sinew also extirpated. Cured within two weeks; patient discharged. A microscopical examination showed that where the first growth had been removed new granulations had formed. These and the destroyed sinew, as well as the axillary glands, which had been extirpated, were found to contain a considerable number of tubercle-bacilli. They mostly were met with alone, here and there

two and three were found together, and many of them were provided with spores.

Several months later the patient was still in perfect health; the stump was in excellent condition, and, notwithstanding the most thorough physical examination, no disturbance whatever could be detected in the lungs.

The case is decidedly interesting. As far as we know, the pus from a panaritium has never been examined with a view to discover micro-organisms. The co-affection of axillary glands in the case of inflamed fingers is by no means a rare occurrence. We must, therefore, express our doubt, if the direct infection in T.'s case was proven. The girl may have had a common felon, and the latter may be caused by bacilli, *looking* very similar to those of tubercle; for already three such kinds of bacilli exist (glanders, tubercle, and anthrax,) which can only be distinguished from each other by pure culture and study of their different behavior while thus developing. Still, it is possible that a panaritium is always due to tubercle-bacilli of a separate species.

Cocaine in Acute Affections of the Upper Respiratory Passages.

Dr. J. Strahan thus writes in the *Brit. Med. Jour.*, June 13, 1885:

The fact that Jellinek has produced complete anæsthesia of the larynx by the application of cocaine, points to a vast field of usefulness for that drug, not hitherto explored. To secure anæsthesia of the larynx, epiglottis, palate, and pharynx, must prove an invaluable boon to the profession and the patient, in the immediate future. Even the action of carbolic lotion or lozenge in throat affections, as an anæsthetic, is by no means to be despised; so that we can easily imagine the comfort, relief of pain, and even avoidance of danger to life in cases of spasm of the glottis, likely to result from the use of cocaine. It has been used with perfect success in operative procedures about the larynx, but has not yet been tried for either diphtheria or croup. It is obvious what a boon the addition of cocaine applications would be to any plan of treatment. It could be applied either by ordinary swabbing with a four per cent. solution, or by insufflation with the dry powder; or the solution could be sprayed when we wished to reach far down. Even if the applications had to be made as often as every half hour, for a little, the trouble would be as nothing compared with the ease and safety of the patient. In case of necessity, the nurse could apply it perfectly well in any form, if taught. The addition of a couple of drops of chloroform (a solvent of cocaine), to the ounce, would prevent the formation of fungus in the solution, as it does in the case of solutions of atropia, morphia, strychnia, tartarated antimony, and indeed all solutions usually spoiled by fungi. This would conduce to economy, as the solution without any preservative soon spoils, and is then liable to excite acute inflammation in mucous membranes instead of curing it. Of course the chloroform must be dissolved in the alkaloidal solution, by agitation in a bottle not more than three-quarters full. This amount of chloroform causes no irritation, even in the eye, as I constantly use preserved solution of atropia, without causing the slightest pain.

We have now evidence that a four per cent. solution of cocaine painted on the nasal mucous membrane, besides causing anæsthesia, contracts the capillaries, drives out the blood, and causes a membrane swollen and red to become shrunken and pale. In coryza, even where the nares are obstructed by swelling, a strip of lint, soaked in the solution and pushed into the anterior nares, speedily removes the swelling, permits the passage of the breath, and, repeated once or twice, even permanently cures the disease. From these considerations, it seems to me that cocaine is destined to become an indispensable aid in all acute inflammatory diseases, of the upper respiratory passages. In laryngitis, croup, diphtheria, scald of the larynx, simple or reflex spasm of the glottis, and even in chronic laryngeal affections, life often depends on the absence of fits of spasm; and the only remedy, when it occurs often enough or severely enough to threaten life, is tracheotomy. If cocaine, by inducing complete anæsthesia of the parts, prevents these spasms even in part, it will be an invaluable addition to the treatment of these diseases. We have some evidence that it will do so, from the fact that the imperfect means on which we have hitherto had to rely for anæsthetizing the larynx, pharynx, etc.—namely, bromides and chloral—do very markedly diminish the tendency to spasm of the glottis in croup, for instance. For that reason, among others, I am of opinion that a combination of bromide of potassium and hydrate of chloral constitutes the very best treatment for croup—at least, so far as systemic remedies go. The bromide diminishes the number and intensity of the laryngeal spasms. The chloral, in addition, acts as perhaps the most powerful antiphlogistic we have in such cases; it greatly reduces arterial blood-pressure, diminishes body-temperature, and acts as a powerful germi-

cide, both generally and locally. The local use of cocaine, and the constant inhalation of some efficient antiseptic vapor, such as that of eucalyptus-oil, or of turpentine and tar, in addition to the internal treatment described, and with proper attention to alimentation, would seem to me to be an almost perfect therapeutic plan for diphtheria, croup, and many other diseases of the respiratory passages.

Anomalous Coronary Artery of the Heart.

To the Academy of Medicine in Ireland (April 24) Dr. Brooks communicated a case of anomalous coronary artery of the heart, which occurred in a subject in the dissecting-room of Trinity College, towards the close of the winter session, 1884–85. A large branch arose from the right coronary artery, about one-third of an inch from its origin, and passed behind the root of the aorta and pulmonary artery; here it gave off three branches, which ran upwards on the trachea; it then divided into branches which anastomosed in a complex manner with an abnormal branch, which arose from the right anterior sinus of Valsalva of the pulmonary artery. From the anastomosis so formed, two branches ascended in a tortuous manner in front of the bifurcation of the pulmonary artery and the transverse portion of the arch of the aorta, and united into one trunk, which joined an abnormal branch arising from the left subclavian artery near the origin of the vertebral. The three branches mentioned above as ascending on the trachea, after inosculating very freely, gave off a branch to the right bronchus, and then joined a branch arising from the posterior aspect of the arch of the aorta, close to the termination of the transverse portion.

Dr. Purser said that it was difficult to say how the blood flowed in this complicated arterial arrangement. One thing was clear—that, in a case of direct communication between the pulmonary artery and the aorta, the current must be from the latter into the former.

Dr. Heuston thought that the vessel described was a vein conveying the blood back from the junction of the normal and abnormal coronary vessels into the pulmonary artery.

The Production of Phantom Tumor.

The *London Medical Times*, June 13, 1885, says that Dr. Krukenberg, of Bonn, contributes to the *Archiv für Gynäkologie* (Band xxiii., Heft 1,) an article on this subject. In a case of the kind under his own care—a case, that is, of apparent enlargement of the abdomen which disappeared entirely when the patient was anæsthetized—he examined the patient very carefully to find out how the swelling of the abdomen was produced. He came to the conclusion that it was due to lordosis of the vertebral column, this lordosis being dependent upon weakness of the spinal muscles due to anæmia and debility. By the lordosis, he thinks, the space in the abdominal cavity is lessened, hence the pressure within it raised, and the anterior abdominal wall thrust forward by the pressure of its contents. Acting upon this theory of the disease, Dr. Krukenberg treated the patient by keeping her at rest, with pillows, etc., so arranged as to support the pelvis, and thus counteract the lordosis; and under this treatment the abdominal protuberance disappeared. He candidly admits that his theory does not account for the persistence of the apparent tumor in such cases where the patient is lying down, unless hysterical contraction of muscles be assumed; nor, we may add, does he explain why similar phantom tumors are not a regular accompaniment of the lordosis due to progressive muscular atrophy, a condition which suggested to him the theory that weakness of the spinal muscles was the cause of the disease in his case.

An Obscure Popliteal Aneurism Simulating Sarcoma.

The diagnosis of popliteal aneurism is not generally a matter of great difficulty, still some of the cases of aneurism simulate other diseases so closely that mistakes are occasionally made. Many able surgeons have opened aneurisms, supposing them to be abscesses, and others again have tied the femoral artery for malignant growths, mistaking them for aneurisms. There are not a few cases recorded where an old consolidated aneurism has been mistaken for a sarcomatous tumor. In the January issue of *The American Journal of the Medical Sciences*, Dr. Francis J. Shepherd, of Montreal, reports an obscure and instructive case of popliteal aneurism, which was under observation for several weeks, and in which there was a total absence of aneurismal symptoms, and the rational symptoms pointed to sarcoma, either of the periosteum or the parts about an old popliteal aneurism, for which the patient had been successfully treated some years before. Amputation was performed, and an examination of the tumor showed it to be solid throughout and composed of fibrin, solidified *en masse*. The orifice of the aneurism was at the distal end of the tumor, and the blood therefore flowed from below up, with, of course, a lessened

stream; the circulation, owing to the obliteration of the femoral above the tumor, being carried on by collateral branches. As there was no cavity in the tumor, the absence of pulsation and bruit is explained. As there was not a single symptom which pointed to aneurism, an accurate diagnosis seems to have been impossible.

Œdema of the Glottis in Tabes Dorsalis.

Any phenomenon may be met with in the course of tabes dorsalis; at least, this statement would seem to be a warrantable conclusion from known facts. We must not lose sight of the circumstance that accidental phenomena also exist and may occur in tabes dorsalis, as in any other disease, without any special significance. M. Huchard read at a recent meeting of the Société Médicale des Hôpitaux (*La France Médicale*, June 2) a paper on a case of œdema of the glottis, following the administration of iodide of potassium in a patient the subject of tabes dorsalis. There was no history of syphilis or alcoholism, and no evidence of Bright's disease. The man was treated on account of the locomotor ataxy with four grammes of iodide of potassium per day. The treatment had to be suspended owing to the induction of iodism. After some days the medicament was given in smaller doses. This renewed treatment was followed by grave attacks of dyspnœa, which threatened suffocation. M. Gougenheim detected œdema of the arytenoid region by laryngoscopic examination. During one of the attacks the "interne" was obliged to perform tracheotomy. The patient ultimately did well. M. Huchard thought that the grave result was largely due to the influence of the iodide of potassium, whilst admitting that a sensory disturbance in tabes dorsalis may have played a part in the occurrence of the phenomenon. Chemical examination of the iodide of potassium showed that it was impure and contained a certain amount of iodates.

CORRESPONDENCE.

The Alcoholic.

EDS. MED. AND SURG. REPORTER:—

Drunkenness is a disease as well as a sin, and this fact explains the effort which the drunkard usually makes to conceal his habit. A guilty conscience forces him to the expedient of concealment and deception, until his mind becomes so ruined by the action of alcohol that he grows more and more without hope or regard, and finally makes his appearance as the despicable sot. The expression of his face is a distortion of God's image, the burden of his frame is the embodiment of disease, and the sin of his soul is the measure of the eternal curse of God. In his rapid progress towards disease, death, and everlasting condemnation, he has always many chances to reform, and many opportunities to return to rectitude and sobriety; but an effort at self-restraint he will not, as a rule, make; and his habit hurries him down, down, through pain, vice, and sin, to a premature grave. In his progress towards destruction, he becomes the pest of society, and his hand more than all others most frequently dyes the earth with the blood of his fellow-man. He commits *five* of every *six* of the murders of a community. The alcohol which he drinks makes him crazy, and an impetuous feeling of wildness takes possession of his poisoned brain, and causes him to be uneasy, impatient, and restless. If not too drunk to walk he cannot remain long in any one place, and his restlessness heedlessly drives him along, to wander in a manner that renders him unconscious of where he is going. Women and children flee affrighted from his approach, and, like a strange beast in the streets, he will stop and stare with wild eyeballs upon the objects that he meets, and then stagger on in the way the maddened caprice of the moment may drive him. The alcohol inflames his brain to acute insanity; and he will shoot or stab his father, mother, brother, sister, wife, child, or any one, who may give the least cause of irritation to his excited passions. Every community has its supply of such alcoholics, and every legislature has passed laws for their arrest as soon as they make their appearance publicly drunk; but the law is not enforced; and it is but *barbarity* to allow them, thus insane, to go wildly through the streets, without an arrest which would rescue them from the fate that might befall them, or the acts of violence that they might commit.

THE INUTILITY OF ALCOHOL.

If there could be found in the habit of drunkenness power to arrest disease, or force of a medical nature to cure disease when present, then a great demand might arise among a people to encourage the habit by a perpetual legislative license to publicly sell the compounds of alcohol as an indispensable necessity to maintain health; but no such plea can be put forth to sustain the popular use of alcoholic drinks; for of all the causes of disease and death, in a community of mature life, the habit of drinking stands far above any other. Retrospection will confirm this conclusion. Let any one review the adult deaths around him, and he will find, in a large majority of cases, that drunkenness, directly or indirectly, was the prime cause of many an untimely death.

ALCOHOL IS NOT A FOOD.

Alcohol was thought at one time to be a food and was supposed to possess nutritions properties; but this was soon found to be a mistake, and it was justly concluded that a substance capable of producing, when taken into the stomach, such destructive effects on the functions of the organs of the human body could in no manner be regarded as a food, and it is now rightly classed among the poisons. Scientific experience has recognized the fact that under no circumstances,

or combination of circumstances, can alcohol be made a necessity to life; and its thoughtless and indiscriminate use as a prescription or medicine has worked harm in every community.

TRANSMISSION OF ALCOHOLIC DISEASES.

I believe it to be the duty of the physician to discourage the use of alcohol at all times, within and without the medical profession; and the cases are so rare in which it is really needed, and is truly of much actual service, that it could be readily expunged from the list of medicines with great advantage to mankind; and I further believe that the physician cannot too often or too forcibly impress upon the minds of those with whom he may be brought in professional contact the facts in relation to the diseases produced by the habitual use of alcoholic drinks; for as a man and a Christian, no subject connected with the fate of society is more worthy of his serious and solemn consideration.

God will not prosper a people who habitually practice the sins that He has cursed; and this decree is carried out by nature in causing physical vice to descend in line from parent to child. This is the most fearful and lamentable physical evil of the drunkard's life. The morbid degenerations of his body and the deteriorations of his mind, produced by the use of alcohol, are transmitted to those who descend from him, and, as a consequence, the offspring comes into the world afflicted. Therefore, the individual who inflicts upon himself all the mischiefs produced by alcohol, and transmits to his progeny not only his disposition to drink alcohol, but the diseases engendered by it in his own body, is clearly a fit subject for legislative investigation, and every Legislature should make him a more serious matter of deliberation than the passage of the license act that tempts him to get drunk.

It is the result of daily observation that the persistent effects of alcohol on the mind and body of the drunkard are noticeable in his appearance and evident in the weakened mental and bodily nature of his children: for it has been decreed that neither the drunkard nor his offspring can possibly escape the force of the curse which the Bible pronounces against drunkenness.

SANITARY LEGISLATION.

It is but brazen mockery for Congress and the legislatures of the States to pass laws creating Boards of Health to investigate cholera, smallpox, and yellow fever, while such legislative bodies pass laws to license the public sale of the compounds of alcohol, and by such proceedings encourage drunkenness, which kills annually thousands of times more men and women than the three terrible diseases combined, and more than all other causes associated, produces the greatest predisposition or fitness of the human body to take and to die from such diseases; but outraged nature always avenges itself, and drunkenness is ever present and ever by the side of the legislator, with its staggering step, palsied hand, maniacal mind, wild eyes, and puffed and reddened face, to jeer him for his lack of legislative care and discrimination, and to mock by disappointment his efforts, with short sighted plans, to improve the sanitary condition of communities.

It is probably not all superstition to believe that the epidemic diseases which now and then visit mankind with terror and death are visitations of God's providence, for they come when we know not, from where we know not, and go when we know not, to where we know not; but it is the sum of all sensual and vicious promptings for the legislator not to believe that drunkenness, which is of man's invention and perpetuation, is not the most fearful and destructive curse of the community that tolerated it; for were it not for the diseases, poverty and filth, engendered by drunkenness, there could exist but little fear of the spread of epidemic maladies. Then why should legislators blindly stagger, like drunken men, in the passage of laws in reference to the preservation of the health of the people, or physicians anywhere hesitate to declaim against a legislative act, the evil influences of which renders the most arduous portion of their endeavors often unprofitable and nugatory?

J. B. JOHNSON, M. D.

Washington City, D. C.

How to Take a Pill.

EDS. MED. AND SURG. REPORTER:—

Not wishing to give a history of the pill, let me say that the pill has been rapidly gaining ground—and deservedly so. In the pill we have the exact dose always at hand, it is cleanly, and we need not trouble with spoons and bottles; it is a preserver of drugs, especially in the easily soluble sugar-coated form. Further, the bad taste and disgust left behind by some medicines, as also the discoloration and bad effect on the teeth are entirely avoided.

The pill takes the medicine where it belongs, to the stomach and intestine. In my opinion, the pill will push to the wall a great many of the liquid forms in which some drugs are dispensed to-day.

A very large class of persons cannot swallow a pill of any description or make; to this class I belonged until last winter, when I had occasion to take chininum sulph., and by a simple method that Dr. E. S. Hanna told me of, I was enabled to take pills as easily as the most confirmed pill-consumer.

Another class of persons succeed in taking pills but by a mighty effort, sometimes hours before taking the dose they begin to make up their minds, as we say, to swallow it without any ado, but as the hour for taking the dose draws near they think of jellies, preserves, prunes, etc., in which to more easily swallow the pill, and even then how often does it end in failure?

The modus operandi of Dr. Hanna's method which I had tried with complete success on many patients, who were taught by their former experience that it was impossible for them to swallow a pill—at least, in the ordinary way—*is to place one or more pills under the tongue.* I repeat, to place one or more pills under the tongue, then take a mouthful of water or other liquid and swallow (just as in the act of drinking); this done, look for the pill. Invariably the "I-can't-take-a-pill-patient" is astonished, and sometimes he investigates the mouth with his fingers to reassure himself if he has really swallowed the pill.

The success—secret—as you wish, lies in the fact that in the act of drinking the tongue curves

back upon itself, the pill, taken by the force of the current, is imperceptibly washed down the œsophagus.

I suggest that the druggists in this as in other countries will have the directions, as above, "how to take a pill," printed on every prescription label intended for pills.

Further, for this country, I would propose these directions be given in German* as well as in the English language.

Further, I suggest that every editor of a newspaper in this, as well as in other countries, under whose notice this may chance to come, will give this simple method, how to take a pill, a space in their paper, and thereby do a large class of readers a real service, which they will receive with grateful recognition. H. Asthalter, M. D.

3716 *Butler street, Pittsburgh, Pa.*

News and Miscellany.

Proceedings of the Kentucky State Medical Association.

REPORTED BY ALLEN KELCH, M. D.

(*Continued from page* 55.)

THURSDAY FORENOON.

Dr. M. F. Coomes read a paper on

THE VALUE OF LOCAL AGENTS IN OPHTHALMOLOGY.

He spoke highly of atropia in the treatment of iritis, both as an anæsthetic and a mydriatic, favoring its combination with morphia, especially in phlyctenular inflammation. This solution in the cases of children should, however, be carefully watched; he had known alarming symptoms to manifest themselves after the use of one drop in the eye of a child of an $\frac{1}{8}$ grain solution. Its value is less since the introduction of the hydrobromate of homatropia. Comparison was instituted between the individual agents of the legion that have been used and recommended as local applications. Out of all the number the speaker had derived excellent results from the application of the muriate of ammonia, either in solid stick or saturated solution, to the conjunctiva in cases of sluggish hypertrophied papillæ of long duration.

Dr. L. S. McMurtry, of Danville, read a report of a

CASE OF LIGATURE OF THE SUBCLAVIAN ARTERY,

in the third part of its course, for traumatic axillary aneurism, with subsequent incision of the sac and recovery. The patient was a robust man, aged 30 years, who, thirteen months previously to the operation, received a pistol-wound of the shoulder, the ball passing deep in the vicinity of of the shoulder-joint. In a few weeks a small lump appeared in the axilla, increasing in dimensions until at the time of operation it had reached the size of a child's head. The tumor occupied the entire axillary space, burrowing up beneath the pectoral muscles; paralysis of the arm, forearm, and hand resulted from pressure exerted by it upon the brachial plexus of nerves. The operation was performed two days after the patient called for advice. A silk ligature was thrown around the subclavian at the external border of the anterior scalene muscle. Pulsation at once ceased in the tumor and never returned: the radial pulse, which had been feeble and fluctuating, was annihilated.

The patient made a prompt recovery without complication. On the twenty-first day the ligature came away. One month afterwards the patient returned to his home, and was not seen for four months. Then the tumor had materially decreased in size, without pulsation and tenderness. The paralysis remained. A ligature was now applied to the axillary on the distal side of the tumor to control hemorrhage from collateral circulation; the tumor laid open, the clots removed, and the patient is now making a good recovery and will soon be able to resume his occupation as a farmer.

It is not surprising, said the speaker, when the conditions are considered, that ligature of the subclavian for axillary aneurism is followed by the frightful mortality of forty-eight per cent. Although embodying the principles of the Hunterian operation it is not far removed from the method of Auel. Indeed, when, as in the case reported, the aneurism extends above the acromial thoracic branch, the circulation through the sac is completely arrested by the ligature. Hence, suppuration of the sac from the loose formation of the clot and secondary hemorrhage are to be anticipated. Again, the ligature is placed in the vicinity of large branches. These facts explain the high death-rate. The case is illustrative and the type of a class circumscribed traumatic aneurism. In these cases it approaches in character the pathological form of the disease, with this important exception—the coats of the artery above and below the tumor, are not involved, and are free from disease. It is this feature which makes this class of cases distinct from idiopathic aneurisms, so far as prognosis and treatment are concerned. In eight cases of this class of aneurisms of the axillary resulting from stabs and gunshot wounds treated by ligature of the subclavian cited by Mr. Erichsen, not one fatal result occurred.

In discussing the paper, Dr. W. O. Roberts cited a case in which the subclavian was ligatured by him three times in succession, at intervals of two weeks, on account of secondary hemorrhage, death finally taking place in spite of everything.

A report was next made on

ORTHOPÆDIC SURGERY,

by A. M. Vance, M. D., in which he advocated the resection of joints in cases of infantile paralysis, with the view of producing bony anchylosis in the best position for use and appearance. He accepted the prevailing view of most authorities, that the results following treatment of infantile paralysis occur spontaneously, the treatment instituted simply preventing deformity and assisting locomotion. This he recorded as his experience in the effort to revive the muscles lost. He referred to the unsatisfactory results of apparatus on account of the difficulty of harmonizing the weight of those sufficiently strong with the weakened condition of the patient; yet without their use deformity is certain to occur as the

patient grows older and heavier, and hopeless crippling is inevitable.

In order to accomplish without artificial bracing a degree of support sufficient to prevent deformity, it has been suggested that the residue of the paralyzed muscles have a section removed, thus gaining by an inelastic band better control of the joint below; and in some forms of talipes, calcaneous for example, that the tendo Achillis be resected to gain an inelastic band for support.

A third suggestion, to excise the useless joint, producing bony anchylosis, I have taken the opportunity to put into practice. The hopelessness of these cases otherwise, coupled with the fact that the bone in young subjects readily heals, renders the prognosis far less grave than in the operations performed where bone disease already exists.

Such operations should not, however, be undertaken without the consent of the parent, after a full knowledge of its import and possibilities. Volkmann suggested such operations in 1881. It was not, however, till May, 1882, that your committee found opportunity to put the suggestion into practice. The operation was then performed upon a boy nine years of age, having a history of infantile paralysis since two years of age. The case was one of extreme valgus, in which the apparatus had been used for several years with unsatisfactory results. The bony anchylosis produced secured good locomotion. An incision was made three inches long, widening midway between the internal maleolus and the tendon of the tibialis anticus muscle in the axis of the extended foot, the center of the incision being over the annular ligament. The joint was opened and the foot broken off the tibia, the ends of this bone and the fibula being removed with the ordinary saw. The upper surface of the astragalus was shaved off with a strong bistoury, the bones brought into contact, the wound closed with stitches, and a counter-opening made for rubber drainage tube, no hemorrhage occurring except from the shaved surface of the astragalus; this was controlled by bruising the surface with the handle of the bistoury. Surgical fever reached 102° F. In three weeks the external wounds had healed, though this had been delayed by the excessive secretion of synovia. This boy has now been walking three years, with three-fourths inch shortening of that limb.

In a second case, the knee was excised in a boy aged seven, where paralysis had existed six years. Locomotion entirely by crutches. An incision was made along the inner border of the patella, having the joint for its center. The patella was removed, the ligaments divided, and the ends of the bones easily exposed and sawed off. The external hamstring was left unmolested, it being the only muscle of the thigh which had any vitality left, and which by its contraction had produced luxation and rotation of the tibia. In ten hours after the operation the temperature had risen to 105° F. Reasoning that nothing but malaria developed and rendered active by surgical procedure could produce such a temperature in so short a time, quinine was given liberally and continued for some time with the desired effect. In eight weeks he was out of bed; in three months the wound and counter-opening reopened completely, following the formation of pus. Firm bony union, however, now exists, and the boy can walk quite well. This operation was done in October, 1884.

In another case the ankle-joint was excised in a young woman æt. 25, the subject of talipes equino varus. In this case correction had been completely made by tenotomy and retentive apparatus four years before. In this case there being complete relapse before the operation, there has been a good recovery, the progress of which was interrupted about the third week by diffuse cellulitis of the anterior part of the calf, which yielded readily however to treatment. She can bear her weight upon her foot, but is not yet allowed to walk.

In a fourth case, subcutaneous osteotomy of the femur below the trochanter relieved an angular deformity of the thigh from hip disease, the femur standing at an angle of less than 90° to the pelvis, the deformity being greater because of high dorsal disease preventing lumbar compensation. Patient could stand only with great difficulty, his mode of locomotion being on-all-fours. After the osteotomy was complete, tenotomy was performed upon the muscles going to the anterior superior spinous process. The wounds were dressed with compresses of absorbent cotton, and the case treated as simple fracture, the boy being able to walk at the end of the fourth week.

In a fifth case of deformity, in a boy seventeen years old, the result of knee-joint disease, the joint retained but little motion, the leg being fixed at an angle of 135° and much rotated upon the thigh with marked genu valgum. This was overcome by osteotomy of the lower end of the femur. He now walks with a comparatively comely limb, a compensation of one and a half inches being added to his shoe.

Thursday Afternoon.

Dr. Dudley S. Reynolds read a paper on

Some of the Causes of Failure in Operations for the Correction of Squint.

After the introduction of the subject, said he: "In 1862, Donders gave the first hint at the real causes of convergent and divergent squint. Before that time, central lesions of the nervous system, traumatism, and habit were regarded the most common causes. Graefe was quick to apply the optical principle suggested by Donders. Others took up the subject, and in 1864, when Donders wrote his great work on the anomalies of accommodation and refraction for the New Sydenham Society of London, he presented to the world a clear and well-nigh complete analysis of all the varying forms of squint demonstrating the causes both predisposing and exciting, and showing wherein Dieffenbach's already universally adopted tenotomy had not been attended with that degree of success necessary to establish it as a universally-justifiable operation.

"What Graefe regarded as lost physiological sensibility through psychical exclusion Mooren correctly interpreted as deficient refraction. Strangely enough, however, Mooren did not establish the relations which abnormal refracting power sustains to the accommodative function."

Further on, Dr. Reynolds said:

"To be plain, the world now recognizes in all

the various forms of squint a certain relation to the acuity of vision depending upon irreconcilable obstacles to the harmonious fixing of the two eyes upon a single object. The focusing power and the accommodative power are not the same, yet they are intimately associated with each other, and any disturbance in their normal relations may create the predisposing cause of some form of squint; active accommodation implies the power of harmonious convergence of the optical axes of the two eyes, and a normal power of fixation. The fixing power will depend mainly upon the state of the perception, while the converging power will depend upon the normal state of the recti muscles, and these in turn upon normal nerve and blood supply as well as constitutional vigor. Central nerve lesions may, by disturbing motor branches, create spasm in the muscle or paresis. The pressure of morbid growths may exercise similar power."

As a conclusion, later on, the speaker said:

"I am persuaded that the first step in all cases should be directed toward the correction of errors of refraction; first to the acuity of vision, and subsequently to the inharmonious muscular action."

This done, in a later paragraph the following occurs:

"If the subject have no organic defect other than the insufficient refraction, the squint may be corrected by suspending the patient's accommodation, and correcting the error of refraction. If organic change has occurred, this must be corrected by tenotomy, carefully done, the error of refraction being at the same time overcome by the use of suitable glasses."

The speaker then traced the deleterious effects upon the mental development of children the subject of these deformities, and showed how many cases of that chain of nervous phenomena, now called neurasthenia, are the results of errors of refraction and deficient accommodative power, suggesting, of course, for their relief the correction of these abnormal conditions.

In a brief summary, said he:

"Failures in the attempt to correct squinting are to be attributed to neglect on the part of the surgeon to rectify at the same time deficiencies in the refractive and accommodative powers of the eye; neglect of the patient to observe the rules laid down for this purpose, and more rarely, perhaps, to bungling and unskillful execution of the tenotomy."

The paper was not discussed.

Dr. Wm. Cheatham read a paper on otology, in which he confined himself to a few points in the proper management of acute catarrh of the middle ear. He said the treatment of these affections had recently become simplified and more efficacious. To their bad management many cases of intractable chronic ear suppuration can be traced. Four cases were reported, showing the efficacy of proper treatment, which consists of leeches, hot-water injections, and a dose of calomel and soda, with a chlorate of potassium gargle. At the end of three or four days' inflation, by Gruber's method, is also employed. If there is much pain, opium is also used. Poultices, he said, were injurious in this class of cases, the hot water and leeches being far more beneficial.

This paper, also, was not discussed.

STRYCHNINE AND MERCURIC BICHLORIDE IN THE TREATMENT OF PHTHISIS

was the title of a paper read by Dr. T. D. Fink. After reporting five cases treated in this manner, all of which did well, Dr. Fink spoke as follows:

"Bichloride of mercury in the treatment of tubercular phthisis is in part based on the theory of Koch as to its pathology, a theory that might well be graced with the term fact, for there is none more clearly demonstrated nor so generally accepted as this.

"In treating tubercular phthisis a medicine must be sought that will antagonize its cause, one that will destroy the germ. Must we needs look beyond bichloride, the greatest germicide, the king of antiseptics—an agent that has so won the confidence of its advocates that many, notably Schaede, of Hamburg, since using it regards a compound fracture with but little more concern than a simple one. But should we deny it first rank among germicides, there is still a plea for its use. It has been established that the bacillus flourishes in the strumous subject. Bichloride changes the soil, so to speak, rendering it less favorable to the development and multiplication of the germ. It promotes absorption of the organic element of the tubercle. It hastens the elimination of effete matter, which, remaining in the system, would itself, through diastatic properties, incite rapid oxidation, hence tissue waste.

"Strychnine proves a most valuable congener. On account of its effect on the sympathetic ganglia it arouses the *trophic* nerve, so to speak, to proper performance of function. Under its influence the demand for nutriment on the part of the individual tissues is expressed in an augmented appetite, and the food taken is digested and assimilated, thereby preventing the vomiting. By checking night sweats and colliquative diarrhœa," said he, "we meet two of the most important factors in the case, and two of the most persistent ravishers of the patient's strength.

"Yet while extolling the influence of the bichloride and strychnia, I do not," said he, "forget that other important factors are to be taken into consideration, and that the cough must be allayed, fresh air supplied, and that animal food is a desideratum not to be by any means ignored in the management of these melancholy cases."

Dr. J. P. Thomas, of Pembroke, committee on Pharmacy, had found kairine undoubtedly antipyretic when a dose of 12 to 15 grains was reached, but in sufficient quantities to lower the temperature it had in his hands produced such profound depression of the heart as to require cardiac stimulants; its antipyretic effect proved to be short-lived, also requiring frequent repetitions of the dose. Paraldehyde he classed among the mild soporifics.

(*To be continued.*)

A Dutch Account of Hottentot Pathology.

From a foreign exchange we learn that a Dutch practitioner who has lived for twenty years in South Africa, sends to an Amsterdam medical journal some particulars of native customs and beliefs. The uterus is supposed to have a great

tendency after parturition to fly upwards, and consequently after the second stage of labor the funis is carefully tied to one of the woman's great toes, so as to prevent the placenta from slipping away, and as soon as the third stage is completed she is tightly bound with a cloth or a cord at the level of the umbilicus, for if not the restless uterus would ascend into the breast. After the birth of a stillborn child nothing can prevent the womb from betaking itself into different regions, and then performing unpleasant and painful gyrations. The writer mentions an old native woman who came to him with a scirrhus of the mamma. She complained of occasional pain in the abdomen, but was not seriously concerned about it, for, said she, "I know what that is; it is the womb going round; have I not had a stillborn child? From that time there can be no rest for the womb; he (the womb) keeps springing round and round, not always, but at times, perhaps for three months, and then for a fortnight he is still. Sometimes he sits here (indicating the spleen); sometimes here (touching the right breast); sometimes he sits behind my shoulder-bone, and then he burns like a coal of fire." The uterus has to answer in the native mind for most of the ills to which female flesh is heir; has she a colic, sickness, or any abdominal trouble, it is always the old story—"the womb is going round." When listening to a gesticulating patient describing her malady, and enunciating her diagnosis of the case, it is frequently somewhat difficult for a medical man to keep his countenance. It is utterly useless for him to attempt to reason with the woman or explain to her the absurdity of the position she has taken up. She will only doubt his skill, and scornfully reply, "Doctor must not say it is not so, for I know that it is." Amongst the natives the new-born babe is treated to a purifying draught of the father's freshly-passed urine. The whites, some of whom are nearly as ignorant and superstitious as the natives, employ a quack "wonder-essence" as a substitute.

Items.

—At the recent meeting of the American Climatological Association Dr. William Pepper, of Philadelphia, was elected President.

—Chloral hydrate has been used by Dr. Rodriquez, of Brazil, in gr. 7½–10 to ℥i. of water three times daily as an injection in gonorrhœa.

—In ganglion of a tendon, Dr. Nancrede (Polyclinic) finds the best results for subcutaneous evacuation of the gummy contents of the cyst and then free incision of the sac. The sensitiveness of the skin is first reduced by the rhigolene spray.

—A gentleman made the following return to the Income-tax Commissioners of Calcutta: "For the last three years my income has been somewhat under £150; in future it will be more precarious, as the man is dead of whom I borrowed the money."

—The latest method of applying a mustard poultice is by means of a sponge. The plaster is prepared in the usual way, the sponge is dipped into it, then wrapped in a soft handkerchief, and applied to the part. By simply warming the sponge again and moistening it afresh, it may be re-applied, the strength being perfectly preserved.

—The physician is frequently asked by lady patients for something that will remove "moth" and freckles. A writer in the *Pharm. Zeitung* says that a wash consisting of equal parts of lactic acid and glycerin will do the work, and is harmless when applied to the skin.

—A new idea in quack medicines is threatened, says the London *Globe*. Hitherto one medicine has been put forward as a cure for all maladies; the new idea is to have a separate nostrum for each disease. Instead of a panacea, we are offered a specific. The only precaution is not to take the hydrophobia pill when one merely has the toothache.

—Dr. Hitchcock, President of the State Board of Health of Michigan, claims that 49,000 Americans die each year from the direct and indirect effects of alcohol. He shows the fearful percentage of idiocy, insanity, and criminals from this source, and the money value of health and life sacrificed. The cost of maintenance of the sick, the idiots, insane, etc., the cost of funerals, etc., reaches the enormous sum of $200,000,000 each year.

—Dr. Morse, of San Francisco (*Pacific Med. and Surg. Jour.*, May, 1885), reports a case of ligature of the common carotid artery prior to removal of a growth from the pharynx. Fearing the use of anæsthetics, he injected over the site of ligature three-quarters of a grain of cocaine and a quarter grain of morphia. The artery was ligated, then, beneath the omohyoid, without the patient feeling any pain.

—Apropos of German surgery, an exchange says that some one, imbued with the spirit of the Arabian Nights, has observed that there are men walking about in Germany without viscera, or with but a fractional part of the proper anatomical amount. Metres of their intestine have been resected; their spleens have been removed; one kidney has gone; they have neither pylorus nor gall bladder.

—The *National Druggist*, May 22, 1885, says that the oldest medical work extant is that known as the "Papyrus Ebers," a papyrus roll found in the necropolis of Thebes a few years ago, and which is now known to date back to the sixteenth century B. C., or nearly 3,500 years ago. The manuscript is singularly complete, not a word or letter being missing, and the inks, which are black and red, being as clear and bright as though written only a few months or years ago. It was written by the priest-physician Nebsecht, and treats of the preparation of medicines, etc. Professor Ebers has recently published a complete translation of the manuscript, which is of intense interest to physicians and archæologists.

MARRIAGE.

HARRIS—MARTIN.—March 11, 1885, at "Marengo," the residence of the bride's parents, by Rev. W. A. Boyingham, assisted by Rev. A. Broaddus, D. D., Dr. J. T. Harris, of Hedgesville, West Va., and Miss R. Lewis Martin, of Caroline county, Va.

SURGICAL TREATMENT OF INFANTS.

BY DEFOREST WILLARD, M. D.,
Of Philadelphia.

(*Continued from page* 89.)

Hare-lip will early require the careful study of the surgeon, situated as it is upon the portion of the body that is most regarded in the *cosmetic* point of view. Its proper relief therefore becomes not only a matter of surgical skill, but of surgico-artistic taste. The time for the performance of the operation is a point upon which there is a wide diversity of opinion. My rule is to relieve the deformity within three or four days if it interferes with the proper nursing of the child. Practically I must confess, however, that by the end of the operation the milk has left the mother's breast, unless there is some other baby to maintain the flow. My preference is to wait about three months, until a full, vigorous activity of growth and cell-action is at work, and before the process of dentition has commenced. This period is selected not only for the reasons mentioned, but also because the child cannot use its hands as freely as at a later period of infancy, thus avoiding risk of injury. In one patient, a year old, diphtheria appeared on the day following operation, and in his convulsions all the pins were twice torn entirely from their fastenings and the fresh wound became implicated. In spite of such complication, an excellent result was obtained by holding the parts in position for days with adhesive plaster cut in the form of a triangle, sufficiently large to cover at its base the area from in front of the ear to the corner of the hyoid bone, with its apex prolonged at the width of the upper lip to meet a similarly shaped piece from the opposite side. These sections were united by a small elastic ring, which maintained a constant pull upon the tisues of the cheek, and controlled spasmodic muscular action. In fractious children I have now abolished pins and have substituted catgut sutures for the mucous surfaces, which, if of small size and tied in three knots, will remain in position until union occurs. For the skin edges I use carbolized, interrupted silk sutures, my reason for stitching the surfaces separately being that there is less linear depression of the cicatrix, and less constriction of tissues is thereby exercised than by pins and figure-of-eight, while if each set penetrate half-way through the lip antero-posteriorly the sphincter is thoroughly controlled. One of the stitches should pierce the coronary arteries. To prevent any pouching of the flaps or separation of the deeper parts by oozing, horse-hair drainage for a few hours answers the best purpose. Additional control of muscles should be given by adhesive plaster prepared as above indicated, or by strips, which should not only be applied transversely, but, in order to prevent strain, should commence upon the neck on either side, in front of the sterno-mastoid near the cornu of the hyoid, and run thence just above the angle of the mouth across the opposite malar to the front of the ear. If these are all put in position while the surgeon pinches the cheeks well together, he will find upon releasing his grasp that the minimum of tension is exerted upon the stitches. A still better plan is to have the nurse regulate this

muscular action for the first few days by pressure whenever the child cries or eats. Only by securing union by the first intention can we hope to have a narrow cicatrix; hence, I do not allow the child to suck, as is the practice with some surgeons, but prefer spoon-feeding as producing less disturbance. For the same reason, anodynes should be employed to control pain and keep the little one for a few days in a quiescent state. The child should be in the best possible condition physically, as quick union is desirable. To avoid the marginal depression so commonly seen and which is inevitable if the simple inverted-V incision is used, I never sacrifice any portion of the paring; but commencing the incision at the apex of the cleft, it is stopped just before it reaches the border of the lip, thus leaving a base of supply to nourish the flap which remains on either side. These two flaps, when the parts are brought together, project downward and form a fleshy prominence; but, if stitched nicely together, will unite, and from subsequent absorption during the next year will give a slight projection. Even should this be larger than desirable, it is far preferable to the ugly notch which cannot be corrected, since a simple scissor-cut will remove all redundancy and give a nearly normal lip. The same rule in regard to utilization of tissue holds good in complicated cases of hare-lip when it becomes necessary to save as much of the alveolus as possible. Broken or cut, it can often be worked to advantage in bridging the chasm or supporting a fallen nasal septum.

If *cleft-palate* co-exists with hare-lip, an additional necessity for early treatment is present, since the closure of the lip will tend greatly to lessen the gap in the hard palate. Dentists realize more fully than surgeons how slight is the pressure required to act upon a tooth or upon the alveolar process; but a moment's reflection will convince any practical man that such narrowing can be accomplished, even if he has never witnessed it. In these instances, as in hare-lip and many other deformities, neglect is often as much the fault of the physician as of the family. An early operation upon the lip, strong pressure upon the maxillary bones, followed by the use of a Hainsby's compressor, will in a few years bring the cleft so closely together that a simple operation will unite the edges.

These are the considerations which influence me in advising that, while the lip should be closed early, the cleft-palate operation should be deferred until the plan has been tested. Few children from five to ten are tractable enough to endure the pain of a staphylorraphy without ether, which is desirable, and I see no particular harm in delaying the procedure until the latter period, save that the unused or malused muscles will require a longer period of education after closure. In a recent staphylorraphy upon a boy of sixteen, the letters of the alphabet could, however, all be correctly pronounced in three weeks, except the k and hard c sounds. If a good velum and uvula can be secured by union, the hard palate can be admirably assisted by an obturator. Only last week, by preliminary touching and the use of cocaine I was able, in a child of five years, to make the parings without pain, and thus avoided anæsthesia until hemorrhage had ceased; ether being employed for stitching only.

Tongue-tie is a condition that exists more frequently in imagination than in reality, yet the operation for its relief need be no more than the most trifling nick of the frænum, the finger completing the work. If the organ can be protruded to the red border of the lip, no operation is necessary.

Club-foot is a deformity which is frequently neglected, not alone from the apathy of parents, but, as is shown by the cases which come under my notice, far more frequently from the incomprehensible advice of the family physician, who has counselled that "nothing shall be done for the present." Weeks slip away into months, and months into years, during which time one set of muscular fibres and one set of ligaments have become elongated, while the opposite ones are atrophied, condensed, and shortened. Bones, too, have become distorted and wedge-shaped, and the difficulties have of course increased fourfold with each advancing year. I have never been able to comprehend any reason why delay should be countenanced a single day after birth, since manipulation and subsequent fixation can easily be accomplished at the first dressing of the child. I know of no words sufficiently strong to characterize such neglect of duty as is seen in numerous instances. Twice in the last three days have I had this matter brought before me by parents who have come to the office and who have given as the reason of their inaction that the physician had directed them to wait. Even before the age for walking, great condensation of tissue will take place, and increase of deformity will occur from simple pressure of clothing, but as soon as the weight of the body is brought to bear upon these misshapen members the change will be rapid. The secret of cure of club-foot lies not in operation, but in careful attention to all the means of relief.

At the first hour of birth, as I have said, manipulation should be commenced by bringing the foot from the abnormal into a normal position, or as near it as possible, and confining it there by wood, felt, binder's board, or leather splints, rightly adapted. At the next visit, leather, gutta-percha, or preferably, printer's blanket cinctures (*a* and *b*), should be laced upon the foot and leg, and connected by an elastic strap. The two-ply printer's blanket, with its rubber face, does not slip even when applied with only moderate tightness, thus being superior to other materials. Hook-eyelets are easily inserted by any shoemaker, and the lacing need not impede circulation. Manipulation can be practiced twenty times a day without taking off the apparatus, while removal at night gives opportunities for massage, frictions, etc. If co-operation of parents is wanting, plaster-of-Paris can be employed with excellent advantage for fixation, a gain being effected with each month's renewal of the dressing. Leather, felt, sheet-lead, and silicate of soda are of use, but do not permit removal for manipulation, and are, therefore, inferior to the bands already mentioned. Those bands, which permit of constant elastic traction day and night, are very inexpensive, if remnants are bought. Their use puts the successful early treatment of any case of talipes in the hands of the ordinary practitioner for the first few months of life. In cases which are of a severe type a subsequent operation is usually necessary, but the manipulation which has been practiced up to the time for tenotomy stretches condensed tissues and increases nutrition, so that relapse after division of the tendons will not occur if the same measures be continued subsequently. Failure after tenotomy is nearly always due to the neglect of manipulation. The special form of apparatus is far less important than a strict attention to details. The chief advantage of the shoe which I employ lies in the fact that it permits manipulation and stretching without removal, owing to its flexible sole-shank of upper leather, which acts as perfectly as a ball-and-socket joint, the force being exerted by an elastic strap (*b*) operating upon the foot through a cat-gut cord passing through the eye (*a*) attached to the upright (*c*). The eye-bearing arm is ordinarily constructed with too little of an outward bend. If I can control the patient, I rarely operate until the tissues are thoroughly stretched; but if the foot cannot be placed upon its plantar surface at eight or nine months—that is, when the age of walking arrives—tenotomy should be delayed no longer, since each step will increase the deformity. In operating, I divide every tissue that interferes with perfect straightening, whether it be tendinous or fascial. The tendon of the posterior tibial is an exceedingly difficult one to sever in a fat infant with poorly-developed heel. The puncture should be made just below the malleolus, and having placed the back of a tenotome towards the artery, division can be safely made. Tenotomes, as found in the shops, have too long a cutting-surface for infantile work, as the sharp edge will frequently enlarge the external wound unnecessarily. It is my practice to leave the tendo-Achillis until the end of the operation, in order to gain its fixation lower in the leverage required for stretching the parts into position—a procedure which is best accomplished at the time of operation. The amount of power which should be employed in this process is governed by the degree of resistance and the caution of the surgeon, especial care being taken that the force be expended only on the resistant tissues. In the class of cases with which this paper deals—namely, young infants—it is scarcely possible that tarseotomy could be called for, although an English surgeon has thus operated upon a sixteen months' old babe. I now use the gypsum-dressing entirely after tenotomy, since it is not only less expensive, but chiefly because it holds the foot and heel in much better position than is possible by any apparatus, and is less liable to produce sloughing, since the pressure is exerted over the entire surface. The instances where plaster produces a slough are always due to faulty application, mainly caused by some indentation produced during the setting process. If the bandages are smoothly and rapidly applied (salt having been been added to the water in which they are immersed), the surgeon can, by grasping the knee, hold it steadily in place, while with the palm of his other hand placed against the plantar surface

of the child's foot, complete rectification can be maintained until the plaster hardens, and without danger of depressing any region of the cast. A dossil of curled hair placed over the ball of the great toe, and over the prominence of the cuboid or astragalus, when confined in position by the flannel bandage enveloping the foot, will also assist in averting any harmful pressure.

I cannot too strongly emphasize my appreciation of plaster-of-Paris in the treatment of *fractures* in infants, giving, as it does, a perfectly-adaptable material, and yet, when hardened, securing an immobility of the injured part that permits free handling, provided the articulation both above and below the injury is included in the dressing. This is feasible even in fractures near the hip, since the splint can be made to encircle the thorax, and thus prevent the great motion that is always present if only the pelvis is fixed. No risk of injurious swelling need be feared, if a flannel bandage or a thin layer of cotton is first applied to the limb. It is better to saw open a dressing at the end of two weeks, and either tighten it or apply a new one. Silicate and other rigid dressings harden so slowly, the displacement may occur during the process. The fractures occurring during birth are often overlooked for several days, and the fact that the child moves a particular portion of its body freely is not proof that lesion of bone has not occurred. I have seen several instances of fractured clavicle in which the child indulged in most vigorous movements of the arm. These collar-bone breaks are quite common, either from falling out of bed or from careless handling, or from the playful jerking of other children. The under-waist of an older child placed in proper position over the well arm, and pinned tightly around the body so as to include the injured member, often keeps in place better in fat babies than a Velpeau bandage, especially if the hand is secured with a loop. Borated cotton should be placed in the axilla.

Green-stick fractures are best treated by etherizing the child and slowly straightening the bone by hand-pressure. Even should complete solution occur, the result will be good. A slight curve can be reduced by splint and bandage. Separation of epiphyses are practically fractures, and should be treated as such.

Dislocations do not differ from similar injuries in adults, save that they are even more readily replaced by manipulation.

The resultant deformities of *infantile paralysis* are numerous, and are frequently passed over by both physician and parents, under the erroneous impression that nothing can be done for the relief of these poor weakened members. Recognizing that restoration is best accomplished by massage, electricity, etc., and particularly by action, it is my rule never to assist a muscle if it is capable of permitting locomotion, or unless deformity is being produced by non-support. The following are considerations that determine the necessity for apparatus. If a bone is bending, or an articular surface becoming distorted, or a ligament yielding, or muscles becoming atrophied from excessive stretching, or if by applying a support the child can be made to walk, then I always order an apparatus which shall not take the place of the enfeebled muscles or put them in splints, at rest, but which shall render just enough assistance to enable them by hard contraction to accomplish the desired purpose. If rigid steel is used, they will soon relinquish their attempts at assertion of power and enfeeblement will increase. By a judicious adaptation of mechanical appliances, many who are now condemned to chairs and beds can be placed upon their feet. The advisability of tenotomy will depend upon the benefit to be gained by such a procedure. In many cases it will assist greatly in placing limbs in proper position for locomotion, and for this reason its mechanical effect should be thoroughly studied. My observation leads me to believe that it is employed too seldom. The excision and shortening of tendons by suturing is often of advantage. Any irregularity in the length of limbs should be counteracted, lest lateral curvature result.

Nævi, if situated upon exposed portions of the body, must be cured early in life if rapidly increasing in size, and in the majority of cases should be attended to before six months is reached. The question of excision, ligature, subcutaneous ligature, injection, electrolysis, or sun-heat, will depend upon situation, size, etc.

Webbed fingers and supernumerary toes and fingers will yield smaller resultant scars, if operated on during the first half-year of life.

Wry-neck may follow injury to the spinal accessory nerve during labor, or it may be found as a result of some of the exanthemata. If resistant to local and constitutional remedies, myotomy should be performed at the end of a year.

Spinal caries in young children can be retarded by placing the sufferer upon its back between two sand-bags, while passive motion is employed to develop muscular power. A jacket or cuirass may be added if bone-death is rapid, or if difficulty of retention is experienced. Horizontal extension is rarely necessary. I have occasionally seen

lateral curvature in weak infants, caused by the mother's habit of always holding them in one position, the reversal of which custom has, together with constitutional remedies, completed a cure. It may also be the result of a rachitic tendency, which will necessitate the appropriate medicinal and hygienic management. Simple posterior curvature and also lordosis are sometimes found, and should be closely watched, as other symptoms of that disease of malnutrition, rickets, may soon present themselves. Dorsal decubitus should be maintained until the proper treatment has had time to strengthen the child.

Rickets, fortunately, is seen upon this side of the Atlantic far less frequently than on the Eastern shores, and, I am thankful to say, is seldom found in Philadelphia even as compared with New York. In fifty thousand cases in our hospitals, I find that less than fifty are enumerated under rickets and its results, including knock-knee, bow-legs, etc. Its onset is usually within the first six months of life, but unfortunately many cases are not brought to the notice of the surgeon until one or two years have elapsed and great deformity has already resulted. When pronounced, the most rigid care should be taken to prevent the distortions from which no bone in the body seems exempt. The effects upon the female pelvis are most disastrous, as life is thereby endangered. The recumbent position is the only safe one, and must be maintained until the general remedies have time to act, passive motion meanwhile taking the place of active. The *tibial curves* are the most common defects. Very slight bowing is sometimes corrected in the growth of the individual, but we have no more right to expect that such a result will spontaneously occur than that a crooked tree will be blown into the upright position by chance winds. The proper means should always be used to compel rectification. If the bones are springy, then much can be expected from manipulation, pressure, and apparatus properly constructed. During the first two years of life we may confidently hope to accomplish a good result by such means, but in later childhood or adult life, if the deflections are great, the bones rigid, and especially if the curve is anterior, but little can be gained by these means, and osteotomy is the more certain and speedy means of relief. The risks of this operation, if done antiseptically, are but very slight, as the case, if sealed, becomes one of simple fracture. Plaster-of-Paris again gives us the best fixation after operation, and is very comfortable to the patient.

I approve of instruments in lateral bow-legs, but when they fail to secure straight limbs in the class of cases above mentioned, I firmly advocate operation. To permit the deformity to continue is not only unsightly, but also interferes greatly with the locomotive powers. It is not true that a bow-legged man is strong. He has, on the contrary, to use his limbs at a disadvantage, and if he is vigorous it is in spite of his complaint.

The question of *tracheotomy* in *young infants*, with whom our present discussion chiefly deals, is one demanding the gravest consideration, whether the dyspnœa originates from diphtheria or from true croup. So fatal are the results, that the mortality in babes below the age of six months is placed by some writers as high as ninety-five per cent.; and even taking all cases under two years, we cannot expect to save more than from ten to fifteen per cent. When we consider, however, that some English writers place the mortality of croup without operation at ninety per cent., we cannot believe that the operation has at least increased the number of deaths. Moreover, when cases are taken at the most favorable age and the most favorable conditions, we can scarcely hope to save more than twenty-five per cent. of all cases operated on. I have spoken thus in regard to prognosis, since some surgeons absolutely condemn the employment of tracheotomy for these young cases. I cannot feel, however, that they are absolutely hopeless, and if surgery can relieve them from the horrid death by suffocation we should not hesitate to give them the aid of science, although a true tracheotomy is well-nigh impossible in a young, fat infant, owing to the exceeding shortness of the trachea and the great size of the thyroid body. It is usually best to do an inferior laryngotomy (or crico-thyro-laryngotomy), making the opening through the crico-thyroid membrane, and also through the cricoid if necessary. The risk of hemorrhage is thereby greatly diminished, since while the crico-thyroid arteries may be cut, they will be far less troublesome to secure than will the vessels about the thyroid body or the middle thyroid artery, which often lies in front of the trachea. Again, the innominate artery may rise high in the neck, or a wound of a vein near the innominate may speedily kill the little one, as has happened in a number of instances even when the operator has been experienced. The fact that surgeons who have opened the wind-pipe several hundred times look upon this operation as an exceedingly difficult one, is proof that the utmost care is necessary. The danger of wandering from the median line may be partially obviated by having the child's head kept perfectly straight and

by placing the body in an exact line with the table. The trachea is sometimes missed because it has not been thoroughly cleared of everything before attempting to open it. The puncture should be made firmly but guardedly. The size of an infant's trachea will surprise one who has never studied it. Although I had given large and special study to the anatomy of childhood, both from the cadaver and clinically, my first tracheotomy case died on the table before I could insert the tube, my error being in trying to push the canula too far back. Unless the urgency is great, ether should be given in moderate amount and the operation carefully performed. A plunge into the trachea is never good surgery; in infants it would be worse than folly. If a circular piece is taken from the crico-thyroid membrane and cricoid, and a pilot used, introduction will be rendered more easy. In fat necks, the windpipe may be brought nearer the surface by extending the head far backward and by grasping the tube on either side and dragging it forward. If fixed thus in the median line, and retained continuously by an assistant, much time will be gained. In a recent case I found it wiser to go above a large thyroid body, even in a five years' old child, and insert the canula in the crico-thyroid space. There was afterwards a slight burying of the upper edge of the plate, owing to its high position, but a strip of sheet-lead obviated this difficulty. To arrest the venous hemorrhage, just before puncture, hot-water sponges answer admirably. After operation the temperature of the room should be kept above 80°. I have never opened the larynx to remove a foreign body in a very young child, but the universal habit of making the mouth the general receptacle of everything makes the introduction of such substances exceedingly probable at from one to two years.

Foreign bodies in the nose which cannot be seized, if not removed by sternutatories, should be always sought for with the aid of anæsthetics.

In the ear the opposite rule holds good, since consciousness of pain will often prevent an unskilled practitioner from doing great injury to the membrana tympani.

Joint-diseases are best treated by recumbency, with fixation or extension.

Excisions are rarely performed at this early age, and need not, therefore, be discussed.

I omit strumous and syphilitic diseases, and a score of other conditions which might well detain us for hours, since time forbids.

I have thus, gentlemen, hastily touched upon only the more frequent of the surgical maladies met with in daily practice among infants. Many of the suggestions may be already familiar to you, but even the brief mention which I have been allowed to bestow upon each subject may possibly have served to revive in your minds old and forgotten experiences, and thus be helpful. You will at least see that the field is a wide one, and that results are most encouraging.

DISEASES OF THE SPINAL CORD.*

BY PHILIP ZENNER, A. M., M. D., OF CINCINNATI,

Clinical Lecturer on Diseases of the Nervous System, Medical College of Ohio.

The reason for preparing this paper was the great frequency and the difficulty in many cases of diagnosis. He thought frequent errors in diagnosis often due more to absence of knowledge of the leading factors upon which the diagnosis is based than to the obscurity of the symptoms.

In proof of this, and to present the subject in a practicable manner, he presented cases selected from his case-book. In these cases errors in diagnosis had been made by men of prominence. We can see in these cases the salient points in the diagnosis, and illustrate the ease with which mistakes are made.

Case 1. Mr. W., æt. 38, had been treated for rheumatic pains. History of frequent paroxysms of severe lancinating pains in the lower extremities for several years; also, various anomalous sensations, numbness, and fomication in the limbs, a sense of constriction about the waist, etc. Found some impairment of sensation in the lower extremities, a degree of insecurity on the feet when the eyes were closed, an absence of the patellar tendon reflexes, and impairment of the gait, which was worse at night. The symptoms in this case were so pronounced that there was no excuse for an error in diagnosis. The diagnosis of locomotor ataxia is based upon the history of characteristic lightning pains, peculiar sensations, and difficulty of walking at night, with localized anæsthesia, inability to stand firmly with closed eyes, and absence of patellar tendon reflex.

Yet cases occur in which the diagnosis cannot be so readily made. The following symptoms, even at an early period, will enable us to make a positive diagnosis. There are the characteristic lightning pains, the absence of the patellar tendon reflex, and certain ocular symptoms. These latter are transitory paralysis of some of the ex-

* Abstract of paper read before the Ohio State Medical Society at Dayton, June 4, 1885.

ternal muscles of the eyes, causing double vision the so-called Argyle Robertson phenomenon, the pupil being small, not responding to light, but contracting during the act of accommodation, and more rarely atrophy of the optic nerves. One other early symptom to which probably too much importance has been attached is the Brach-Romberg symptom, inability to stand firmly with closed eyes.

Case 2. Mr. K., æt. 35. Difficulty in walking for six years past, also slight bladder symptoms. Locomotor ataxia had been diagnosed, but the conditions presented were quite different from locomotor ataxia. The gait was feeble, not ataxic, with often a feeling of stiffness in the limbs. Patella tendon reflexes exaggerated, also the foot clonus could be elicited. The three cardinal symptoms in locomotor ataxia were not present. The swaying of the body when endeavoring to stand erect with the eyes closed was present. This is, however, often misleading. In locomotor ataxia the posterior columns are the seat of disease. In this patient the changes were in the antero-lateral cords, the disease usually termed lateral sclerosis. Its symptoms are motor paralysis, rigidity or spasmodic contractions of the muscles, and exaggerated tendo-reflexes. You may say there is little practical difference, and nice diagnoses are not necessary, but the difference is of considerable consequence. The subjective symptoms of locomotor ataxia are severe, those of lateral sclerosis insignificant, while the prognosis of the latter is decidedly better.

Case 3. Mrs. U., æt. 30. Observed weakness in lower extremities four years ago, was unable to lift her feet in walking as well as formerly, nor rise easily from a sitting to a standing position. Weakness later invaded the deltoid, biceps and quadriceps femori of both sides, as well as many of the muscles of the back. The patient's manner of attaining the erect position was especially noticeable. To extend the knees, she pressed the hands upon the thighs, then raised the trunk by means of a chair. This effort produced a remarkable curving of the spine in the lumbar region. One physician suspected disease of the vertebræ.

In this case there was, in addition to the paralysis, atrophy of the muscles and loss of electrical excitability. This latter is a point of much importance. These, together with the history of gradually extending paralysis, are quite enough to diagnose progressive muscular atrophy, though in this case the development was an unusual one.

Case 4. Mrs. L., aged fifty-two years, had been operated upon for carcinoma of the mammary gland. Eight months later, severe pain like that of intercostal neuralgia occurred. Subsequently, severe pain in the lower extremities, hyperæsthesia of the surface, and paraplegia, with some atrophy of the muscles of the legs. Myelitis had been diagnosed. Author emphasized the gradual access of the symptoms, the severity of the pain seldom, if ever, found in ordinary myelitis, and the history of previous malignant disease. Upon these facts he made the positive diagnosis of malignant disease within the vertebral canal and prognosis of a fatal issue within a year. The subsequent history strengthened the diagnosis. Patient died in nine months. Post-mortem showed numerous carcinomatous nodules both in the vertebra and in the cord. The earlier manifestations were quite sufficient to make a correct diagnosis. Paraplegia, with pain so severe that paraplegia dolorosa has been used to designate it, is rarely, if ever, found, excepting with malignant disease. A previous history of this disease should leave no doubt of the diagnosis.

A few cases of neurasthenia would contrast well the functional and organic diseases of the cord, but would occupy too much time. The essential thing is to exclude organic disease. If a patient comes to us with a history of pains, weakness, or anomalous sensations pointing to the cord, we should examine as to the presence of ocular symptoms, as to the condition of the cutaneous sensibility, as to the tendon reflexes, and the action of the bladder and rectum, and the kind of gait, to know of the presence of locomotor ataxia. We should then examine further to see whether any motor paralysis, with increased tendon reflexes and rigidity of muscles, point to disease of the motor columns of the cord. Or paralysis and atrophy of the muscles, with altered electrical reaction, point to affection of the gray matter. If all these symptoms can be excluded, we are probably in the presence of only a functional disease, which, with time and proper treatment, can be entirely removed, and whose positive diagnosis will bring immediate mental relief to an anxious, perhaps despondent sufferer.

—In the *Brit. Med. Jour.*, June 6, Dr. J. Fourness-Brice says the number of cases of ague and insanity which make their appearance in the emigrant ships crossing the North Atlantic is simply astonishing. If latent in any individual, they almost always develop themselves at sea; and practitioners on shore do not appear to be aware of the fact, as he finds that in nearly every case the patient has been recommended to "try the effect" of a sea-voyage by his medical attendant.

Hospital Reports.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

CLINIC OF PROF. J. E. GARRETSON, M. D.

Reported by THEODORE STANLEY, M. D.,

Resident Physician to Medico-Chirurgical College Hospital.

Ablation of Half of Tongue.

The disease affecting the patient now in presence of the class is epithelioma located upon the side of the tongue, and, as it is proposed to remove the lesion by an operative procedure, it is desirable that the class appreciate the indications and justification of such a performance; this, particularly in face of the undeniable fact that few operations for cancer of the tongue result in any good.

On extrusion of the organ by the patient, it is seen that while the ulceration involves a large part of its right side, there is a ridge-line of demarcation which has entirely prevented encroachment upon the oral floor. It is to be noticed, further, that there is absence of the diffusive expression; that is to say, the ulcer seems to contain the whole manifestation of the disease. Still, again, feel where we may about the neck, no enlarged glands are found. Once more, there is absence of cachexia; the face of the man blooms in healthful ruddiness, his limbs are round in their paddings of fat.

I now contrast the condition of the present patient with two other cases which happen to be in the hospital.

* * * The three men are now before you. The one whose condition has been considered is young. The two just brought in are old. Epithelial cancer is malignancy itself, and it is common in the aged. In the young, the condition is rare, and it is abeyant. The cases of the two old men are helpless and hopeless; surgery is without power to do more than ease the way. The passage from Carneades applies—

> "Nature did make me, and she does together keep me still,
> But yet the time does come when she will pull me all to pieces."

The pulling to pieces has commenced. Observing diagnostic and prognostic features, you will remark that neither old men can respond to a request to project the tongue. Both speak with an indistinct mumbling utterance. Both show large and hard swellings below the jaw. Both have cachexia, manifested in a cadaverous expression.

Looking next within the mouth, it is noticed that specific ulcers exist which involve the tongue, oral floor, tonsils, and soft palate; no lines of demarcation are anywhere to be seen; infiltration is without boundary.

If these two old men, worn out and suffering, were philosophers of the academic school, it would be an occasion of rejoicing with them to learn that an end was drawing near—end which is ever the beginning of a new end. What a good to these two old men would it be if we could make them comprehend the remark of Plato: "From the dead, Clebes, living things and living men are produced."

Once upon a time I wrote, myself, something to the same effect. "Hard is the fate of mortals," sighed a locust, as he felt his efforts all too feeble to resist the unseen something which was thrusting him out from what he called himself; but on another day coming back and beholding the dry shell that still adhered to the tree—the old shell which had grown so crusty, and hard, and colorless, and which had so cramped and so constrained him—he said to a companion, "How great a fool is a locust?"

Ovid puts into the mouth of Pythagoras some meaning lines in the direction of our digressing thoughts:

> "Death has no power the immortal self to slay,
> That, when its present body turns to clay,
> Seeks a fresh home, and with unminished might
> Inspires another frame with life and light.
> So I myself (well I the past recall),
> When the fierce Greeks begirt Troy's holy wall,
> Was brave Euphorbus, and in conflict drear,
> Poured forth my blood beneath Atrides' spear;
> The shield this arm did bear, I lately saw
> In Juno's shrine, a trophy of that war."

I see the direction in which your eyes are turned. You conclude right. Coca and morphia, not philosophy, will best meet the indication as to euthanasia. It is, I accept, a truth, that only the initiated of the Epictetian school may comprehend the truth that "*the body is an external.*" Truly is ignorance the evil, the only evil of the world. There is little difference between our ignorant man and a locust.

Yet how comparative a thing is learning: euthanasia in the present example for the old men, immediate cure for the young man. Knowing no specific for cancer, we are at absolute loss when the vice lies hidden in the deep parts. We are able alone when the length of a knife-blade can reach the extent of a lesion. We have no help for the old men here in our presence because the disease lies deep. We will cure the young man, because the trouble limits itself to the surface.

Understanding why we operate or refuse to operate, I proceed to the treatment of the young man. An ablation of the tongue, or any part of it, is accomplished by means either of knife, scissors, ecraseur, or ligature. In the present instance I will employ both of the latter named means, with a view of exhibiting the ease with which a comparatively complicated thing may be done.

The intention is to remove one half the tongue. In my hand is a heavy and curved needle of blunt point having a large eye. Here is a stout and waxed thread, having attached, near the end which I shall relate to the eye of the needle, the chain of an ecraseur. The probe-pointed needle being threaded, I take up a long and curved bistoury and pass it through the tongue from below upward and backward until it emerges at the root of the organ. This knife held in place, I follow the line of its blade with the curved needle, and as this emerges at the dorsum, the blade is withdrawn. Next, chain and ligature are pulled through, the needle being unthreaded and the ecraseur detached from the twine. Let it be now observed that a double means of strangulation is possessed, namely, ecraseur and ligature. As it is a succeeding intention to cut with these means at right angles (with the ecraseur longitudinally

from base to apex along the median line, and with the twine from base to side), it becomes necessary to secure fixedness to the chain and thread, which object is attained by the use of needles in positions indicated, the strangulating means being cast over and to the outside of these.

* * * Things being now in condition for the ablation, a loop is threaded to the apex of the tongue, and as the organ is pulled forward out of the mouth, you are to observe that there is included within the ligatures just one-half the body. So far, we have little blood and less trouble. The completion of the operation consists in the gradual tightening of chain and thread and a consequent slow separation of the parts. * * * The portion is away. Two unnecessary spurtings of blood confront us. The time has been ten minutes; it should have been twenty. The object of strangulation is to crush, not to tear; we have done part of both. The operation is complicated by a necessity for ligating two vessels, a matter not difficult of accomplishment, however.

After-treatment of the case will consist simply of a mouth-wash, pretty constantly employed, made up of equal parts of phenol sodique and water.

Amputation of Breast and Removal of Seventeen Axillary Glands.

The lady lying anæsthetized upon the table, is afflicted with a tumor of the breast, diagnosed carcinoma. The diagnosis of a neoplasm lies with the process of exclusion, while the use of this process lies, in turn, with the possession of an understanding which enables one to say positively what a thing is not. This patient having had the benefit of a consultation with a number of the members of the faculty, none of whom find explanation for the presence of the lesion in familiar derangements or perversions, a conclusion as to its cancerous character is to be accepted as irrefutable.

A neoplasm is a new formation, that is, it is a formation out of correspondence with normal histology. Tumors having their existence in anatomical or physiological perversions, as for instance the head of a bone out of place, or a cyst of retention, have in themselves their own explanation; this not only as character, but as requirements for cure, are concerned. A neoplasm is an arcanum; what surgeons know of it relates simply with crude matters of clinical signification and histological appearances.

It is unsatisfactory not to know all. It was a remark made by Galen that the cause of toothache is known alone to God. Here it is that surgery stands in relation with carcinoma; there is not a single solid reason existing with the profession that casts any light on the subject; cancer is cancer; treatment is mechanical or it is nil.

A class of inexperienced students has very much to learn, however, about phenomenal expressions associated with neoplasms. Some are quickly fatal, others are slowly progressive. Some are hard, some soft. Some are acutely painful. Some poison to the point of death, a local existence all the time undiscovered, perhaps unsuspected. Some run pus, some blood. In some is heredity. Some attach themselves to the healthiest families and constitutions. In a word, rule is absent.

Cancer is studied clinically, as diagnosis is concerned, only in estimating properly the value of the process of exclusion referred to. We say that a tumor is a cancer by demonstrating that it is not anything else. Yet it will be comprehended that the ability to say what a tumor is not, implies necessarily a knowledge of all the known possibilities of a part. It is the manner of the process, however, which makes the matter easy. If, to make an example, a tumor be situated upon a toe, we begin by satisfying ourselves that it is not a common corn, and so on to the end, by exclusion.

As a rule, cancer is to be removed in its very infancy or it is to be let alone. The track by which a neoplasm finds its way into the system, is that laid by the lymphatics. When a gland is found enlarged it is well to accept that the original tumor is no longer a boundary of the disease, and when once the original boundary has been passed, it becomes all guess-work to say where it has even temporary re-establishment. Not long since I followed a chain of these lymphatics from a breast to the axilla, and from here to the subclavicular region, and after removing twenty-three lost them, as they disappeared in the bronchial region, the patient dying later from cancer of the lungs.

In removing the mammary gland, where probable pathological relation with the lymphatics exist, note is to be made of the fact that the vessels run from the gland to the axilla, and that the incisions are to be in consideration of this anatomy. In the present instance I start my cut at the sternal aspect of the tumor, and carry it outwardly and upwardly to the axilla. A second cut, made after the same fashion, exposes the breast in an ellipse. I proceed now to turn out the gland from the sternal side, including in that which I turn out even the superficial pectoral fascia.

* * * Remark now that I have lifted the gland from its bed, but that it is related with the axilla by a confused mass of string-like tissue. Here are lymphatic vessels, and now that a finger can be carried deeply into the arm-pit, I am led to understand by the marble-like bodies felt that I am not to cut away the mamma, but am to follow the lymphatics until I shall pull out and remove every enlarged lymphatic gland felt.

Please notice that, with the aid of my clinical assistant, I am bringing out gland after gland. * * * * Until now we count seventeen, which completes the operation.

Caries of Both Tibiæ.

Our next case is a patient kindly directed to our care by Dr. Prince, where the heart and a portion of the shafts of both tibiæ are involved in specific caries. Constitutionally the cure of the man lies with the gentleman sending him to our clinic. Our office is with the local disease, and the opportunity provides further display for the capability lying with the surgical engine.

NOTE.—Cure of this case was so rapid that the patient was able to leave of himself the hospital on the succeeding Thursday, the operation having been done on Saturday.

NOTE.—This young lady went to her home, unattended, in the State of Maine, at the end of three weeks.

The patient being etherized, I now proceed to expose the affected bones by slits made in the soft parts. Next, using a bur, I open into the tibia, finding, as you see, a honey-comb mass of diseased bone. With the means at command, nothing is easier than the removal of this mass. Note that I am using a bur made up of twenty blades, and which is being revolved at the rate of ten thousand revolutions to the minute. You will observe that even with this immense speed of the instrument, I direct the mandril which holds it precisely as one writes with a pen.

I complete the operation by the free use of a syringe, which, as you see, brings out of the holes quantities of bone debris and dust.

Broken Humerus.

A broken humerus, uncomplicated, needs scarcely more than the show of a chance to come to speedy cure. The indications are, as the class well understand them, to approximate the ends of the bone and retain them immovably in apposition.

This boy broke his arm last night, as he tells me, by a fall from a hay-mow. You observe that there is no swelling, no complication, but that the arm is broken I determine by the crepitation which all hear by listening.

I dress this arm in a simple fashion that any one can imitate. First, I straighten the part, which means setting the bone. Second, I throw around the injured part the turns of a roller. Third, I cut and fit two pieces of wet pasteboard, composing a ferrule to the part and which I bind in place by a second roller. Fourth, I bind the arm against the side. Fifth, I put the forearm in a sling. This last completes the dressing, and I will leave it undisturbed for a week, provided no undue swelling takes place. Next Saturday I will re-dress the case, with a view to showing some other equally simple manner of accomplishing an end. The less frequently a fracture dressing is replaced, the better is likely to be the result.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, April 23, 1885. The president, Dr. E. O. Shakespeare, in the chair.

Notes on the Morbid Anatomy of Pneumonia.

Dr. Osler read a paper summarizing his experience while Pathologist at the Montreal General Hospital. Of 105 autopsies in cases of lobar pneumonia of which notes were available, five were discarded for various reasons. The mortality at the hospital is high on account of the large percentage of grave cases which are admitted, very many in persons debilitated and dissipated.

Of the 100 cases, 70 were males and 30 females. Of 94 instances in which the age was given, there were 11 cases under 20 years, 12 between 20 and 30 years, 18 between 30 and 40 years, 21 between 40 and 50 years, 12 between 50 and 60 years, and 20 cases over 60. In 51 cases the right lung was affected, in 32 the left, in 17 both. Other details were given of the various lobes affected. The heaviest lung weighed was 2303 grammes, and in eight instances the affected organ weighed over 2000 grammes. In about 50 per cent. of the cases there was red hepatization, in 30 per cent. mixed red and grey, and in about 20 per cent. grey hepatization. The condition of the pleuræ, air-passages, bronchial glands, and unaffected portions of the lung tissue, were described. Among the terminations there were four instances of abscess formation, three cases of gangrene, and one in which there was a process of fibroid induration beginning in the lung. This case was a man aged 55, admitted with pneumonia of the right lung, five days after the initial chill. Resolution did not occur, and he died in the fifth week.

Post-mortem.—The right lung was found solid, greyish in color, and in many areas the tissue had a smooth, homogenous, translucent aspect, and in these a fibroid change was going on; the alveolar walls were thickened, and the fibrinous plugs in the air-cells seemed undergoing transformation into connective tissue (a slide was shown illustrating this). There were no caseous portions, and no tubercles.

As to the other organs, the frequency with which large, firm clots were found in the heart was specially dwelt upon. In only 35 instances was the spleen much enlarged. In one it weighed 670 grammes. In 25 per cent. there were marked fibroid changes in the kidneys. Of the complications, there were 5 cases of pericarditis and 16 cases of endocarditis. In 8 instances the meninges of the brain were inflamed, in 5 of them associated with ulcerative endocarditis. In 5 instances there was acute croupous or membranous colitis, and, in one instance, croupous gastritis.

Dr. Tyson, in the discussion of Prof. Osler's paper, said that he had been rather incredulous of the termination of croupous pneumonia in fibroid induration, but the specimen exhibited by Dr. Osler demonstrates conclusively that such a condition exists. The facts presented in the paper are such as are not generally collated. Collective reports of autopsies in cases of particular forms of disease would be of great value in the study of pathology.

Dr. Formad asked Dr. Osler why his was not a case of acute phthisis. Croupous pneumonia is a very common accident in acute phthisis. It is croupous pneumonia which causes death, which is well shown by recent investigations of Mercur, of the University of Pennsylvania. Dr. Formad did not believe that croupous pneumonia can last five weeks.

Dr. Shakespeare said that the remarks of Dr. Osler about the frequent existence of very firm clots in the right heart, extending into the ventricles, can be corroborated by any one who makes autopsies of cases of pneumonia at hospitals. He had seen them in cases of phthisis quite as extreme and firm, reaching into the vessel going to the affected part of the lung. It is interesting to note the systemic involvement of these cases of croupous pneumonia and the affection of internal organs as well as lungs in the process which has been regarded as a local disease. We have to do with a general, wide-reaching affection rather than local inflammation. The opinion was advanced by Dr. Osler that the exudate in the air-cells organized, that the process in the organization of the croupous exudate is similar to that in the clot in arteries after ligation, and that com-

parison was the point which Dr. Shakespeare wanted to bring out. Dr. Shakespeare said that he did not believe that a blood-clot in a vessel ever organizes, and his opinion is based on facts detailed in an investigation which he has published on the healing of arteries after ligature. The vessel healed not by the agency of the white cells caught in the meshes of the reticulum, but by proliferation of the endothelium of the tunica intima and subjacent connective tissue cells. He thought there was reason to believe that there is in this process in the lungs an analogue of the process after ligature.

We have to do with an outgrowth of the interalveolar walls. The ground which Dr. Shakespeare takes is purely that of analogy to the process in a blood-clot in a ligatured artery.

Dr. Osler, in closing the discussion, said that it was well known that croupous pneumonia might persist five or six weeks, or even longer, before resolution took place. It was difficult for any one who had not had the experience to realize the anxiety which such a case would cause. He had reported two such cases of delayed resolution, one in the fourth week and one in the eighth, both with perfect recovery. He was quite aware of the difficulty in distinguishing certain cases of acute phthisis from pneumonia, and had seen a case with Dr. Ross, in which the diagnosis was for some time in doubt; but in the case in question, the person had been under observation from the outset, and the symptoms were those of ordinary pneumonia.

Post-mortem.—There were no caseous masses, no miliary tubercles; only the condition already described. The termination in fibroid induration, though rare, was perfectly well recognized. In Cornil and Ranvier's Manual, as well as in Green's Pathology, was a figure which might have been taken from the slide under the microscope.

Dr. M. H. Fussell, of Manayunk, presented specimens from a case of

Primary Tuberculosis of the Kidneys.

The reporter never saw the subject alive from whom the specimens were removed, having performed the post-mortem examination for a friend.

Case of Edward B., æt. 40, single, by trade a paper-maker. In following his calling, he was forced to stand in a dust-loaded atmosphere from morning until night. He worked at this trade from boyhood, steadily, with the exception of four years during the late war. His grandfather died of bladder trouble; his father died of apoplexy; his mother, brothers, and sisters are all living and healthy. He was always a robust man; his weight was 170 pounds, and he never had any serious illness; he had gonorrhœa during the war. Four years ago, while in camp, he made a misstep and fell. The next morning he passed much blood in his urine; previously to this he was perfectly well. From this time until death he was troubled with slight pain in his loins and with frequent micturition; his urine was sometimes bloody, sometimes milky. The patient's bladder finally became incontinent, and he was forced to wear a urinal.

The patient's general strength did not seem to suffer until the past six months, when he began to lose flesh and strength, and at death he was much emaciated. He had never had any cough or diarrhœa. Two weeks before death he began to vomit; this increased in frequency until he was unable to retain anything on his stomach. Just before death, the breathing was rapid and full. The patient was very restless, vomited, and passed urine freely. The pupils were dilated.

Dr. Fussell examined the urine several times The sp. gr. ranged from 1.002 to 1.010. Large amounts were passed. Albumen was present. The microscope showed pus, blood, and granular epithelium. Many of the cells were irregular in shape, the pyramidal form predominating. No casts were found at any time. Unfortunately a critical physical examination of the patient was never made. At different times surgeons had sounded him for stone, and had failed to find any.

Post-mortem.—Nothing especial noted on the exterior of the body.

Thorax.—Heart about normal in size. The muscle looks normal, and contains a large amount of fluid blood and currant-jelly clots. A small decolorized clot on the left side. Valves normal.

Lungs.—Both pleural cavities obliterated. The pleuritic adhesions were tough, the lungs being with difficulty torn from the cavity. In places, the pleura was much thickened. The surface of both lungs was studded with miliary tubercles. On section, the lung substance was crepitant, and studded with myriads of miliary tubercles. No caseous masses nor cavities were found in either lung. The bronchial glands were enlarged, not caseous.

Abdomen.—Viscera in normal position. Peritoneum free from tubercles, and of a healthy look.

Liver, of normal size and color. Over the surface a few stellate cicatrices noted, but no tubercles seen on the surface nor on section of the organ. The bile ducts free.

The *stomach* contained greenish-black fluid; the mucous membrane of a greenish color corresponding to the contained fluid. The rugæ were much enlarged, especially at the cardiac end. Near the pylorus there was a small injected spot.

Kidneys.—The right measures six inches in length and three in width, and is of a reddish hue; the surface is studded with tubercles; on stripping off the capsule, the larger of these remain with the kidney structure, while some of the smaller ones are torn off. On section, the cortical substance is seen to have a thickness of about one-third of an inch. Numerous foci of softening are seen. Three are of the size of a nickel five-cent piece. There are very many smaller ones, situated mostly in the pyramids. Numerous miliary tubercles throughout the substance of the kidney. The foci of softening are evidently due to breaking down of the tubercles. The ureter is dilated, measuring half an inch across in some portions. The mucous membrane is ulcerated. The pelvis of the kidney is not dilated, and shows miliary tubercles.

The left kidney is large, and is converted into five or six cysts. There is but little kidney substance remaining. The surface of the kidney is studded with a few tubercles. The cysts are lined by a thick leathery membrane, which can be stripped from the kidney substance. On puncturing the cysts, a perfectly clear serous fluid at

first escaped, soon followed by a milky substance containing some cheesy masses. The pelvis is smaller than normal, the ureter entirely occluded.

The supra-renal capsule had undergone degeneration, and is of a uniform yellowish-white color and presented tubercles.

The *bladder* was slightly contracted; the mucous membrane ulcerated; the muscular coat being exposed. The vesicle trigone was of vivid red color, and studded with miliary tubercles.

The *intestines* were normal; no enlargement of lymphatic elements. The mesenteric glands were slightly enlarged. The prostate gland and spleen were not examined.

Prof. Wm. Osler kindly made sections of the kidney and supra-renal capsule, and the REPORTER is indebted to him for the following report:

1. Extensive, widespread, small-celled infiltration between tubules and malpighian tufts.

2. Distinct miliary tubercles, with centrally-placed giant-cells.

3. Areas of softening and disintegration. Tubercle bacilli carefully sought for, but only two undoubted specimens found.

Supra-renal capsule showed miliary tubercle with centrally-placed giant-cells.

Dr. Formad referred to a similar specimen which had been exhibited by Prof. Tyson at a former meeting of the society.

Dr. Osler remarked that Dr. Fussell's case corresponded in all essentials to what we know as tubercular nephritis. The bacilli, however, were scarce and difficult to find. Since the report of Dr. Tyson's case a few weeks ago, he had had occasion to look over the notes of several cases, and found that they formed a complete series, from cases of unilateral disease to instances with tuberculosis of the entire urinary tract, and general infection. The condition was not infrequently met with accidentally in persons dead of other affections.

Tubercle Bacilli in the Urine.—Dr. Osler showed a slide of pus from the urine in another case of tuberculous kidney, with the tubercle bacilli stained.

The president, Dr. Shakespeare, reported a case of

Intestinal Stricture.

The patient was admitted to the Philadelphia Hospital one week previous to her death, under the care of Dr. Evans, the house physician. She had obstinate constipation, followed by stercoraceous vomiting. She suffered acutely, lapsed into an unconscious state, and died, all treatment proving ineffectual.

At the autopsy, the thoracic organs were found apparently normal. In the right iliac fossa a lobulated tumor was apparent on opening the abdominal cavity. The colon was distended with gas in the transverse portion, and in the descending portion was narrow. The ascending and transverse portions had hardened fæces. There was a double twist of the intestine, and two strictures—one in the ileum, two inches above the ileo-cæcal valve, and one two inches below the valve. They would not admit the finger. There was a ring of hardened tissue in each stricture. There was congestion of the mucous membrane in the small intestine, and adhesion of the first part of the ascending colon on its under surface to the abdominal parietes. The kidneys were normal. A large tumor of the right ovary was also present, attached to the uterus.

Dr. Formad, who made the autopsy, remarked that acute peritonitis had in this case become chronic, and that it was the contraction which made the strictures. The cause was probably the abdominal tumor. He was not aware that there was a case on record where a tumor produced stricture. The donstriction was due to outside pressure.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, June 26, 1885. In the absence of the President and Vice-Presidents, Dr. Charles K. Mills occupied the chair.

Dr. D. M. Barr reported a case of

Carcinoma of the Uterus,

in which the patient had resorted to the "faith cure."

Early in January, 1879, I was called to see Mrs. S., aged forty-six years. She had been suffering at intervals for the last few months from severe uterine hemorrhages. On examination, per vaginam, there was found a cauliflower excrescence involving the posterior, and part of the anterior, lip of the os uteri, but not involving the vagina. An operation was decided upon, and in the presence of Drs. C. A. Groff and J. G. Heilman, the cervix uteri was removed, close to the body, by means of an ecraseur. The wound healed kindly without leaving any trace of local trouble. For two years and a half the patient enjoyed good health, having no evidence of trouble, but she always had some mental forebodings. At the end of the third year some hemorrhage occurred, and examination revealed granulations of a specific character apparently involving the entire endometrium. An application of Vienna paste was made, thoroughly cauterizing the whole surface; the symptoms were thereby arrested, and the patient enjoyed good health for another year, making *four years* of good, vigorous health, when hemorrhage again occurred. Examination now revealed a marked epithelioma, involving the vaginal walls, the body of the uterus was enlarged, and evidently, also, involved in the trouble. Palliative means were resorted to, but there was no hope of eradicating the disorder. The patient became greatly alarmed, and although there was but little hemorrhage and no pain, she sank rapidly, refused all nourishment, and gave every evidence of a speedy dissolution. At this point she made arrangements for the "faith cure"—sought the prayers of a circle and was anointed, after which she declared herself cured. Her general condition improved, and when I met her three months later I did not recognize her, so much better was she looking.

For about a year her health seemed good, and she was able for almost any exertion, but at the end of that time she began to experience some languour, was more easily fatigued, and gradually failed. One day after she had been suffering very severely, I was called to her; found a distended bladder, and upon passing the catheter the patient was relieved. Upon investigation, I found the cancer had never been healed, nor its progress

in any way arrested; it was now filling the pelvic cavity, and the enlarged uterus reached above the umbilicus; this great increase in size having occurred in about two years, the growth having steadily gone on, notwithstanding the apparent cure, and the really vigorous life which the patient had enjoyed during the past year. She died soon after I was recalled. The tumor in itself was painless throughout the entire period of its growth, death being induced chiefly from its pressure upon the neighboring vessels, firm adhesions being formed between the two.

In the discussion which followed, several cases were related by different members of the society, in which persons had resorted to the "faith cure," some of whom were *apparently* cured, or at least relieved for a time.

Dr. Charles P. Turner said that he had known of several cases of nervous inertia which seemed to be cured by the influence of a strong will over a weak one; many of these cases, however, had gone back to their former condition, as this influence wore off. He would believe in the "faith cure" when he saw a case of tuberculosis or cancer cured by that method, and not until then.

Dr. Edward Montgomery said that the cases were of a nervous or hysterical character; such persons come under the influence of some one who has a powerful influence over them, and are made to "arise and walk," and are then reported as *cured*. He related the case of a lady having some organic heart trouble, who wished to try the "faith cure," but the examining physician told her that such cases were not benefited by that method of treatment. So it seems that the cases which Dr. Turner wishes to see cured in order to be convinced of the efficacy of the "cure," are the very ones which are not treated in that way.

Periscope.

Case of Eczema Following the Course of the Small Sciatic and Short Saphenous Nerves.

Dr. Frank Shearar thus writes in the *Glasgow Med. Jour.*, February, 1885:

This eruption is a very interesting one, because of its exceptional character, its evident neurotic origin, and its lengthened duration. It is essentially eczematous in its nature; it extends, as a continuous ribbon-shaped band, from the left buttock to the base of the little toe; it corresponds, to a considerable extent, with the courses of the small sciatic and short saphenous nerves; it has been in existence, in part at least, for nearly eighteen months; it began without any apparent cause, and it has not been associated at any time with neuralgic pains, or with any alteration in sensation.

November 27, 1884.—The subject of this peculiar eruption is a thin, but fairly healthy, boy of thirteen, who has never hitherto suffered from any neurotic affection. Nearly eighteen months ago he noticed that the skin behind the knee-joint had become thickened and roughened, and that it was red and itchy. This condition slowly extended downwards to the prominence of the calf and upwards to the buttock, and latterly, within the last six months or so, it has spread still farther downwards to the little toe, and for four or five months it has undergone little or no change. As it spread, it was red, itchy, and leeted a good deal.

At present the appearance of the eruption is very striking. It is dark red in color; it is covered in many parts by thin scales or scabs; it is distinctly raised above the general surface of the skin; its margins are well defined; it extends as one unbroken band from the buttock to the toe, and the neighboring skin, except at a few points, is perfectly healty. Its breadth varies from three-sixteenths of an inch to two inches. It is broadest on the most prominent part of the buttock, and here its appearance suggests the idea that it has become frayed out into three diverging portions, each little narrower than the parent stem, and separated at their upper extremities by little V-shaped patches of healthy skin, the outer division reaching higher upon the buttock than the middle one, which, in its turn, extends higher than the inner one. At the margins above there are some smaller isolated patches. From this head, the stem of the eruption extends downwards, with a slight inclination, at first inwards, and then slightly outwards, along the inner aspect of the back of the thigh to the popliteal space, and in its course is gradually narrowed till, at the middle of the thigh, it is about three-fourths of an inch broad, and so continues till the knee is reached. It now broadens out somewhat irregularly till it reaches the prominence of the calf, when it begins again to narrow, and forms a regular curve at first downwards and inwards, almost to inner aspect of leg, and then downwards and outwards to a point over the insertion of the tendo Achilles, reaching its narrowest at the point of greatest convexity of this curve. It then bends sharply round the heel, and passes along the outer margin of the foot till the proximal end of the metatarsus is reached, when it curves upwards on to the dorsum of the foot, and ends abruptly at the base of the little toe, where it is about one-half an inch broad.

Immediately below the knee, where the eruption broadens out, the margins are broken by little detached points, and there are two quite separate portions external to and parallel with the main band of the eruption. The superior of these two is in the lower part of the popliteal space, and is a narrow line about one and one-fourth inches long; the inferior is on the prominence of the calf, and is more irregular and patchy but its long axis corresponds with the commencing curve inwards of the main line of the eruption, and it measures three inches in length.

On the buttock, as elsewhere, the eruption consists in a considerable thickening and elevation of the skin; it is deeply furrowed in all directions; the upper portion consists of irregularly circular patches of a dark red color, and of a slightly raw appearance, whilst the other portions and the margins of these patches are covered by thickish white patches of dead epidermis. On the back of thigh the eruption is very regular, and has hardly any outlying portions: the furrows are nearly all transverse; there are fewer patches of red unprotected epidermis, the most of the eruption being covered by a thin scale of yellowish scab, which, at the margins and transverse furrows, has partially separated, and there presents a narrow irregular white line. Below the knee the scabs are somewhat thicker, in the upper portion they are quite unbroken, and the transverse furrows and markings are very distinct, but in the lower parts, here and there, large patches have been denuded, and the markings are rather indistinct. Along the outer aspect of foot the eruption is less vascular; where the red base is exposed, it is much paler, and, for the most part, is covered with thickish scales, at parts yellowish in color with white markings, but towards small toe with white, dry, and almost silvery scales like those on a patch of psoriasis. The margins of the eruption are nearly everywhere marked by a narrow bronzed line of discoloration.

The patient complains only of itchiness, especially at night when he takes his stocking off and in the morning when he rises, and of the stiffness of knee, arising from the thickened and hardened state of the epidermis. There is at present very little leeting.

17th December, 1884. Since last note the patient has been under the care of Dr. Richmond, in the Paisley Infirmary, and the eruption, in spite of varied treatment, essentially retains the characters described above. There are now, however, here and there along a large part of the margins of the eruption, small isolated patches, irregularly circular or linear in form. The small detached portions on buttock are now somewhat larger and more irregular, and have become attached, in all cases, to the main mass of the eruption. For about two inches above the heel the eruption has assumed a warty character, and immediately above the insertion of the tendo Achilles it is very much elevated, dried, and cracked. Looking at the eruption as a whole, one is struck with its regularity except, speaking roughly, in its middle third, where its outer margin is complicated with the detached portions above described.

Two days ago an attack of herpes zoster began to develop on the opposite thigh. Near the sacral end of the cresta ilii, and parallel with it, is an oblong patch of characteristic vesicles, two inches long and one broad. A similar patch is situated five inches vertically below the great trochanter. Another broad patch extends almost continuously downwards and inwards for seven inches, from a point four inches below the anterior superior spine of the ilium; and a smaller patch, arranged in a parallel line to this, is placed over the lower part of Scarpa's triangle. The patient says that the eruption on the other leg commenced in the same way, but asserts that it was not accompanied, as in the present case, with burning pain; and he is quite confident that it was not at any time scattered over the surface of the thigh.

This interesting case differs from one of herpes zoster not only in its character and lengthened duration, but also, and that very essentially, in the relation of the eruption to the nerves affected. In herpes the eruption corresponds with the cutaneous distribution of certain scattered twigs, whilst in this case it corresponds, in a rough way, to the course of the main trunks of the nerves. For, whilst both in the thigh and in the leg a considerable portion of the eruption is decidedly internal to the usual course of the nerves, which may be supposed to be affected, those portions on the buttock and behind the knee correspond, the former with the external cutaneous branches of the small sciatic, and the latter with the lower branches of the same nerve, and that portion on the outer aspect of the foot with the last part of the short saphenous nerve. It is more difficult to understand, in this way, how it could have been brought about. It would almost seem, indeed, as if the cutaneous twigs were not in themselves primarily affected, but were influenced in some way by the altered molecular condition of the nerve trunks acting directly through the subcutaneous tissue on the nerve endings in the skin. The disease was apparently confined at first to the small sciatic nerve, but afterwards attacked the short saphenous nerve, and so may be supposed to be dependent on some central changes in the ganglia of the cord. The recent occurrence of herpes zoster on the opposite leg forms an instructive sequel to the case, and no doubt throws some light upon its true nature, whilst it affords an interesting contrast to it.

The occurrence of eczema in connection with injury to nerves is, of course, not unknown, but the principal literature of nerve or skin disease does not bear evidence of the frequent occurrence of such cases as the above, and hence it may be thought worthy of record.

Cerebral Localization.

From the *Cinn. Lan. and Clinic*, February 7, 1885, we note the following abstract of Dr. Zenner's paper on this subject, read before the Cincinnati Medical Society:

There are a variety of methods of research which have assisted us to our present knowledge of the function of the brain. In the first place the study of comparative anatomy has been one of our greatest and most valuable aids. It has shown us that the seat of conscious intelligence is in the cortex of the hemispheres; this is proved by the greater development of the cortex in man as compared with the lower animals; and again, in the higher races of man the cortex is more fully and elaborately developed than in the lower. The highest power has been proved to reside in the frontal lobes.

Another study which assists in the proper understanding of the functions of the different parts of the brain, is the science of morphology. In the central convolutions of the cortex we have large cells, those of the type supposed to characterize motor cells; while in the occipital regions

we have small cells which in all probability have sensory functions.

The third science which assists in arriving at proper conclusions in regard to the functions of the several parts of the cerebrum is the study of anatomy.

We have very accurate knowledge of the various peripheral parts of the nervous system; if these parts could be followed to their origin our knowledge would be complete; but this is impossible. Yet we have assistance through other means. Prominent among these stands the study of those degenerative changes which result from disease. We have found, for instance, that when the function of a nerve is lost, the nerve itself undergoes various pathological changes. This matter was investigated especially by Turck and subsequently by Goodin. The subject was still further pursued by Flechsig, who studied the natural development of nerve tracts and systems.

But by far our most important factor in reaching a proper conclusion in cerebral localization is experimental research.

To Flourens belongs the honor of advancing science most decidedly in this direction; his work was done early in this century, in the second or third decade. He demonstrated clearly, as it was believed, two vital points: First, that the cerebral cortex is the seat of the will and of consciousness, and second, that all parts of the cortex possess the same functions—though, perhaps, with slightly varying power. This was the doctrine universally upheld for half a century. Then new investigations brought to light facts which showed that Flourens' results were not altogether accurate.

Broca, in his researches in regard to aphasia, came to the conclusion that the seat of speech had a definite situation in the brain; this he demonstrated by various experiments. Some doubt, however, was thrown upon the value of the work of Broca through the negative results obtained by Trousseau. He proved that in at least some cases of aphasia no structural changes of the brain occurred. Yet further study has shown us that Broca's views were correct as far as they went. Soon after Broca came Meinert, who very materially advanced existing knowledge of the cerebral functions, through most careful and painstaking study; his researches are of great value to us today. He held that the cortex is the seat of conscious intelligence, and that all our knowledge is derived from external impressions; all impressions pass through the crura cerebri—except those which we derive by means of the optic and olfactory nerves.

The relative development of the crusta and tegmentum indicate the degree of intelligence which belongs to the being; in man alone are the crusta and tegmentum of the same size; in lower animals the tegmentum greatly exceeds the crusta in size; in young children a similar disproportion exists, which disappears entirely when adult age is reached. The crusta is traced to the corpus striatum, and is connected with motion; the tegmentum is in relation with the thalamus opticus and corpora quadrigemina, and is connected with reflex functions; it is especially developed in infants and the lower animals.

The conclusions reached are that the thalamus opticus is the seat of reflex activity; and the other parts of the crura convey motor impulses.

Shortly after Meinert's researches, Fritsch and Hitzig published the valuable results of their experiments upon animals; they observed that by irritation of certain parts of the brain, there could always be produced definite movements; and these movements were not of the simplest character only, but in some instances were complicated, and were such as required the coördination of several muscles. Objections were raised against these views, but it was clearly shown in the first place, that movements could be affected only when the irritation was applied to a definite part of the cortex. And secondly, though the irritation were applied at other points, however near the corpus striatum, no movements followed. And in the third place, in new-born animals, in which as yet there was no connection between the cortex and the corpus striatum, irritation was not followed by the movements.

Other experiments have been made by the removal of the cortex.

Dr. Hughlings Jackson has shown that the so-called "cortical epilepsy" consists in movements caused by the irritation of a certain part of the cortex.

The seat of the sense of smell is supposed to be situated in the gyrus hippocampi; but we have as yet very little evidence of the accuracy of this supposition. The only experiment bearing on this point is one of Monck; the gyrus hippocampi is situated at the base of the brain, and is consequently inaccessible. Monck observed in a dog, in which inflammation had destroyed this part of the brain, that the sense of smell was entirely lost.

The same investigator locates the seat of hearing in probably the second or third temporal lobe; his experiments were made on the dog.

Ferrier locates the seat of this sense in the first lobe. In the human being, the so-called word "deafness," seemingly dependent upon changes in the left temporal lobe, points to this as the seat of hearing; numerous instances have been recorded of deafness following disease in this region.

With reference to the seat of vision, experiments have more positively established the situation of this sense than of almost any other; numerous cases point to its location in the occipital lobe.

With regard to the seat of motion, experiments and physiology both go to prove that for the mouth and tongue the seat is in the lower part of the central convolutions; for the arms, the middle of the central convolutions; and for the legs, the upper part of the central convolutions.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Two reprints by Dr. J. W. Gleitsmann, of New York city, connected with the German Dispensary, have considerable interest to students of diseases of the throat and nose. One is entitled

"Laryngeal Hemorrhage," the other, "Deviations of the Nasal Septum."

——Dr. David Prince, of Jacksonville, Illinois, has added to the already long list of his valuable contributions to medical science three with the titles: "The Pulley Modification of his Limiting Tenotomy and Advancement of the Rectus Operation," "An Accidental Divulsion of a Pterygium Leading to an Improvement in the Regular Operation," and "Floating Minute Organic Matter in the Air, and its Management to Prevent Disease and to Mitigate or Control it, with a New Device for Atmospheric Purification."

——A curious anatomical case is reported in a reprint by Dr. Wm. A. Edwards, of Philadelphia, entitled, "An Anomalous Human Lung, having Four Lobes on the Right Side."

——The Proceedings of the 12th Annual Meeting of the Alumni Association of the Albany Medical College contain the Alumni Lectures of 1885, and will be found an interesting pamphlet. (Published by Burdick & Taylor, Albany, N. Y.)

——The *New York Nation* printed in its issue of June 25 a retrospect of the twenty years of its existence which were completed with that number. The *Nation* was founded in July, 1856, in recognition of the new order of things which was sure to follow the end of the war and the abolition of slavery. It has been conducted, in its two leading departments, politics and literature, by the same editors from the first number, and holds to-day, as for the past twenty years, the first rank in each. Its foreign correspondence is unrivalled. Its book reviews possess the highest authority. Each number contains a careful news summary, and the bound volumes are prized as the best obtainable chronicle of current history. 24 pp., quarto. 10 cents a number; $3 a year. 210 Broadway, New York.

BOOK NOTICES.

Transactions of the Medical Society of the State of Tennessee. 1885. 8vo., pp. 144. Nashville, 1885.

The usual proceedings, constitution, code, etc., are given in this volume, and also a number of original articles, most of them of solid value. We have been especially interested in one by Dr. Daniel F. Wright, of Clarksville, on the therapeutic effect of the ligation of great arteries. This procedure, first recommended by Dr. Daniel F. Wright, of Georgia, is intended as a remedial measure in traumatic gangrene, erysipelas, and other sequelæ of traumatic inflammation. The main artery of the limb is tied with beneficial results in cases otherwise hopeless. The article deserves the careful consideration of surgeons. Dr. J. W. Penn, of Humboldt, discusses epidemic cholera, and finds its cause in the alkilinity of the drinking water. Dr. T. K. Powell, of Dancyville, urges the value of veratrum viride in puerperal convulsions. This is, however, not a new suggestion, as he seems to think. When veratrum had its great run, some twenty-five years ago, it was used for this and nearly every other disease, but for some reason has "lost its grip" on modern therapeutics.

Cholera: Its Origin, History, Causation, Symptoms, Lesions, Prevention, and Treatment. By Alfred Stillé, M. D., LL. D., etc. 8vo., pp. 164. Philadelphia, Lea Bros. & Co.

This timely little work is full of the learning and good judgment which marks all that comes from the pen of the distinguished author.

Dr. Stillé does not accept the doctrines of Koch and the German school, while he fully recognizes the specific nature of cholera, and its propagation by a peculiar poison. He condemns in severe but just language the official assertion of English physicians that it can originate *de novo*, and also the repeated and dangerous doctrines of those who oppose quarantine as useless. His statements on this point particularly deserve the careful reading of every medical man who has to do with public health.

What he has to say on treatment is characterized by his usual caution and his well-known preference for a rational system which relies on general measures and distrusts specifics. Altogether the monograph is one which will have an excellent influence on the professional mind.

A Treatise on Practical Chemistry and Qualitative Inorganic Analysis. By Frank Clowes, D. Sc., etc. From the fourth English Edition. 8vo., cloth, pp. 376. Philadelphia, Lea Bros. & Co., 1885.

The author has intended this volume to be a laboratory guide and a text-book for students, and that he has succeeded in providing them with a highly acceptable work for the purpose is shown by the rapid dissemination of three editions in England and two in this country. The present one appears with a close revision, bringing it up to the latest acquisitions of the branch to which it is devoted. Its pages are freely illustrated, and both those already acquainted with its merits and those who have that acquaintance to make will not fail to be pleased with the completeness of the treatise in its present shape.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

RUNNING TO CATCH THE TRAIN.

Within a few months past the writer has noticed several papers upon this subject, two of which were in the REPORTER. As this is the time when travel on railroads is, perhaps, at its height, a few remarks upon this matter may not be amiss, as every one must know that desperate, at times frantic, efforts are daily made to catch the train. To a certain extent, as when important business must be transacted at a certain period, or when various events of public, or social character occur, some allowance must be made for injudicious haste. But, however frequently such emergency may arise, it oftener happens that no pressing necessity exists to justify efforts not only injurious, but, at times, actually fatal. Here, however, it must be confessed, that to arrive at a station just in time to see the train start is, to almost every one, provokingly annoying, and well calculated to disconcert the most impassible.

In many cases the efforts to catch the train cannot well be exceeded by the professional runner, whose reputation and pecuniary interest are at stake in a race. The danger of sudden death in these cases may not be great, and, if fatal, would probably not be made known in many instances, while a death from lightning, or hydrophobia, would be noticed by the papers generally. The danger is chiefly in regard to those who are either prone to affections of the heart, or who have, in fact, symptoms of some of the various maladies to which it is subject. In such cases a single effort of tbe kind alluded to may prove to be the efficient cause of a most serious aggravation of the affection, and may terminate suddenly in death, or greatly increase the trouble, that may continue for months or years. If a record of all such cases could be made, it would probably be found that the deaths, or serious injuries, occasioned by lightning or hydrophobia, so much spoken of and dreaded, would bear but a small proportion to those resulting from the daily, incessant, desperate efforts to catch the train.

In this connection, an instance of sudden death, occurring within the knowledge of the writer,

may be alluded to: A gentleman, aged forty-eight years, in company with his two nephews, went to Atlantic City on Saturday, intending to return by the early morning train on the following Monday. Some delay prevented their going to the station earlier, and, as the time of departure was near at hand, they walked rapidly. Another man ran past them, and, looking back, said "they would miss the train unless they ran." They at once began to run with great rapidity, but arrived only in time to see the train move away. The uncle, whose family the writer had attended during many years, and who had never had any sickness, sat down, but in a moment he arose, drew forth his pocket-handkerchief, wiped the sweat from his brow, saying "he would not like to run that way again," and instantly fell down, and in less than a minute life was extinct.

It should, however, here be stated, that although remarkably healthy, he was excessively fat, and, unfortunately for him in this case, was exceptionally active—capable of running very rapidly.

In view of the fact that instances of injury of a serious character must be of frequent occurrence, and at times of fatal import, it would seem to be of importance to remind the public, either by medical or other publications, of the danger to be incurred by these rash efforts to catch the train.

Notes and Comments

Poisoning from Chloroform.

Dr. Llewellyn Eliot presents a case of poisoning from chloroform taken internally, and adds a table of the reported cases (*N. Y. Med. Record*, July 11, 1885).

The table shows that death resulted in 16 cases; of this number but 6 died in twenty-four hours; the other 10 surviving various periods until the eighth day. The mortality was 26.78 per cent.

The mortality of chloroform is 1 to 5,860; that of ether, 1 to 16,542; that of nitrous oxide, 1 to 100,000; we see that chloroform is not an agent to be used indiscriminately nor in the absence of proper antidotes. Deaths are rather due to paralysis of the heart and respiratory organs. When administered internally, the symptoms produced are of the same character, only more intensified and more lasting than those following inhalation.

It is impossible to state with exactness the amount of chloroform that can be administered by inhalation. In a case of puerperal eclampsia that E. brought to a successful termination, one and a half pounds were administered in thirty-six hours. The same holds good in regard to doses by the mouth; recorded cases show quantities varying from ʒss to ʒvj. The symptoms of the toxic action of a fatal dose, in addition to general muscular relaxation, perfect anæsthesia, and insensibility, are cyanosis, convulsions, jaundice, sudden paleness of face and lips, stoppage of the pulse and respiration, involuntary passage of urine and fæces.

In treating cases of internal administration, the first indication is evacuation of the stomach by emetics or stomach-pump. Fresh air, sinapisms, flagellations, cold douche, strong coffee, with ammonia, strychnia, digitalin, or morphia sulphate hypodermically administered, are the measures to be adopted; artificial respiration, lowering the head, drawing the tongue forward, lifting the chin, hot applications and inhalations of nitrite of amyl should be employed.

Electricity is advocated upon theoretical grounds. Dr. Reuss recommends subcutaneous injections of apomorphia. Spence prefers ammonia to alcohol as a stimulant, on account of alcohol increasing the already increased amount of carbon in the blood, while ammonia acts merely as a powerful stimulant. The post-mortem appearances are not pathognomonic. Fifty-seven cases are recorded in the table, extending from 1851 to date.

Double Infantile Spastic Hemiplegia.

In the January number of *The American Journal of the Medical Sciences*, Dr. S. J. McNutt reports a case of double infantile spastic hemiplegia, with carefully recorded notes of the post-mortem appearances, illustrated with seven cuts exhibiting the lesions found. This is believed to be the third, or, at the most, the fourth case of its kind upon record. Yet these cases do not appear to be so very uncommon, since four others presenting similar symptoms are known to be now in New York city. As a distinct condition, even simple infantile spastic hemiplegia has but lately received attention in text-books. For this reason, and on account of the difficulty of obtaining any comprehensive information on the subject, the collection of facts and theories presented in Dr.

McNutt's paper is of great value, and must lead to a further study of this interesting condition. Dr. McNutt has collected and tabulated 34 cases in which autopsies have been made, and each of them presented atrophy of the cerebral cortex, near the fissure of Rolando.

The subjects of infantile spastic hemiplegia may live to old age. The inception of the disease, however, always dates back to early childhood, or to intra-uterine life. At whatever age seen, its victims are characterized by more or less complete hemiplegic motor inability, atrophy, and contractures, with or without aphasia, monosyllable utterance, dysphagia, dyspnœa, and idiocy, the latter being especially characteristic of the double affection.

The etiology of infantile spastic hemiplegia has been defined as primitive defect, arrest, encephalitis, and hemorrhage.

Clinically, the cases may be divided into three classes, those in which the inception of the condition precedes birth, those in which it occurs after birth, and those of which parturition is the cause. The paper concludes with a careful study of the differential diagnosis and treatment.

Treatment of Neuralgia by Neuber's Method.

Dr. Schapiro recently read a paper, at the Medical Society of St. Petersburg, upon the results of researches on treatment of neuralgia by Neuber's method of hypodermic injections of a solution of osmic acid. His observations include eight cases of trigeminal neuralgia (three males and five females). The age of the patients varied from thirty-eight to sixty. In every case the disease was of a very severe type and of long-standing. The result of the treatment was complete cure in five cases (three females and two males), great alleviation of the pain in two cases, and no success at all in one case (female). The number of injections made in each case was from one to twelve (twenty in one case), five to ten drops being injected every time. The duration of the treatment was from one to sixty days. Dr. Schapiro adopts a modification of Neuber's 1 per cent. aqueous osmic solution on account of the osmic acid soon undergoing decomposition in a watery solution. After a whole series of combinations, he concluded that an addition of glycerine to the watery solution prevents for a long time osmic acid from undergoing any change. In not one of the cases treated by him was an injection followed by any ill effect. The patients are now under the author's observation (two to six months after the commencement of the treatment).

Fracture of Humerus by Contro-Coup.

Dr. Geo. E. Monette, of New Orleans, thus writes in the *Texas Courier-Record of Medicine*, June, 1885:

Fred. C., of New York, an exhibitor and visitor to our great Exposition, met with the above accident during December last. While riding in our street cars (*en route* to the Exposition), sitting carelessly in the car, with his elbow as far out the window as he could protrude it, the result was that his forearm met an obstruction in a projecting seat of our ordinary wood-carts used in the city, striking the ulna, about four inches from the olecranon, with such force as to fracture the humerus at the deltoid insertion. The fracture, as also the contusion, did well, until the fourth week, fortunately after union of the fracture, when the most violent periostitis developed at the seat of contusion of ulna. There was an evident exfoliation of the bone, which seemed to have undergone suppurative degeneration, and resumed its normal condition with very little irregularity of its surface. There were a number of sinuses communicating with the contusion and a slight abrasion, which terminated in an ulcerative condition. These were broken up by lotions of tinct. iodine co. and carbolic acid (℥j. āā ad. Oj.). Recovery was good and complete at the expiration of two months.

Cocaine in "Snuffles."

Dr. Zemshchenko has treated seventeen infants from two weeks to eleven months old with coryza by means of cocaine dropped into the nose. Two drops of a two per cent. solution were thus applied from four to six times a day with remarkably good results. In only one case was any increase of secretion observed. He has also made use of a four per cent. solution for older children. As, however, there is some risk of the solution being swallowed and producing vomiting, he finds it best to apply the cocaine by means of an ointment. In one case of suspected "snuffles" in a child three weeks old whose mother was syphilitic, the writer painted the nares with a two per cent. solution with a satisfactory result.

Acute Albuminuria of Possibly Traumatic Origin.

Dr. W. F. Morgan (*New York Med. Record*, July 11, 1885,) writes that he was recently in attendance upon a boy, aged seven, and had considerable difficulty in making a diagnosis until an analysis of the urine revealed the presence of fifty per cent. of albumen by volume.

This condition had not been preceded by any of the specific fevers or other of the generally-recognized causes of acute Bright's disease in children. "Possibly it may have been due to a fall upon the back which the patient had had about a month before. The fall had been succeeded by a gradual deterioration in health, with great disturbance of the heart's action, convulsions and cyanosis. During the convulsive attacks the heart-beats were irregular and about forty per minute. An unfavorable prognosis had been given, but after a month convalescence set in. Diplopia and incoördination of the muscles of locomotion persisted for several weeks, but the patient is now in perfect health.

CORRESPONDENCE.

Hysteria.

EDS. MED. AND SURG. REPORTER:—

In the July 11th No. of the MED. & SURG. REPORTER, 1885, it is related of Prof. W. H. Thompson, of New York, that in one of his recent excellent lectures he related his experience in connection with a case as follows: "The patient was a female of 20 years. After a careful examination a diagnosis of hysteria was made and appropriate treatment prescribed, with no apparent improvement of symptoms. The case was becoming monotonous to physician and friends. A noted metropolitan neurologist was called in consultation, and acquiesced in the diagnosis which had been made, also saying with emphasis, that any doctor with average knowledge would know that it was a case of hysteria. Ere the consultation closed, they were summoned to the bedside of their patient, only to see her expire."

This reminds me of a case that occurred in my practice about a year ago. I was called in great haste a few squares from my office to see a young lady, 17 years of age, of a general physical development much beyond her years, who was, apparently, in that peculiar swoon or quasi-insensible condition we often see in cases of hysteria, not unlike that known as "trance." My opinion was expressed accordingly, which opinion was sustained by the priest who was present. I assured the friends she would recover in a short time, and went home. I no sooner reached home, however, until I was recalled and, upon my arrival, found my patient dead. The *post mortem* revealed a very greatly hypertrophied heart, which, however, might have been diagnosed *ante-mortem*, if a thorough examination had been made.

H. V. SWERINGEN, M. D.

Fort Wayne, Ind.

Pelvic Cellulitis in a Child Three Years Old. Vesical Tenesmus the Leading Symptom.

EDS. MED. AND SURG. REPORTER:—

I submit the following case, its several peculiarities entitling it to notice:

Angerina L——, an Italian girl, aged two years and nine months, a stout, healthy child, well-developed and active, was observed to urinate with great difficulty. Her mother attached but little importance to the trouble, which had existed about two weeks, until the night of September 20, when I was called. I found the bladder very much distended, no water having been passed in eighteen hours.

Failing to relieve the retention by the ordinary expedients, I drew off the water without difficulty, using a soft catheter.

It was necessary to repeat the operation again on the following morning.

After that, I saw nothing more of the case until December, when I was again called under similar circumstances, and at once used the catheter to relieve the retention. This time the patient was sick for several days with fever, constipation, and great pain on micturition. After her recovery, I again lost sight of my patient until June last, nine months from the date of her first trouble, when she was presented at my office much changed in appearance. She was emaciated, peevish, and fretful, her principal trouble now being intense pain upon evacuating either bowels or bladder.

Upon examination, slight tenderness was discovered in the right iliac region. The abdominal walls were rigid.

With Dr. Richardson in consultation, she was anæsthetized and the bladder searched carefully for stone or tumor.

While undergoing this examination, we detected a tumor the size of an egg, hard and firm, just above and to the left of the pubes. This body proved to be the spasmodically-contracting bladder. Examination per rectum revealed a firm, elastic swelling, encroaching upon the rectum from the right fossa. A slight sense of fluctuation was elicited.

The examination was now postponed until the following day, at which time diverse opinions were held by the gentlemen in consultation. Amid so much doubt, we prudently determined to wait a few days and again examine the patient.

On the second day after this examination I visited the child and was shown a supposed stool, which was really nothing but pus and blood.

A large opening was found in the rectum about one inch above the verge of the anus, through which an abundance of pus was being discharged.

A diagnosis was now clear. The obscure trouble, with vesical spasm the only prominent symptom, proved to be pelvic abscess, which was evacuating itself through the rectum.

The discharge continued but a short time. Nutritious diet, tonics, and stimulants, wrought a great change in the child. To-day she is free from trouble and pain of any kind; in fact, appears perfectly well.

Matthews Duncan holds pelvic cellulitis to be always a secondary affection. "That it is produced by inflammation of the uterus, or of the tubes, or of the ovaries, or by noxious discharges through or from the tubes and the ovaries, or by mechanical injury. Without one of these causes this inflammation and abscess is not observed." (Emmet.)

Thus from these distinct, but not always clearly defined sources, this high authority traces cellulitis; and it does appear that he has embraced all the factors in its etiology.

To what then are we to attribute those cases fo cellulitis occurring after the menopause, or before puberty, in which we can eliminate almost positively the existence of such a cause or complication?

In the case detailed, there could be but one of the above causes possible in its production, viz., mechanical injury. There is no history of a fall or an accident of any kind. A soft rubber instrument and utmost care were used in catheterizing, so I can honestly eliminate mechanical injury.

All tissues of the body under favorable conditions are subject to inflammations. I am unacquainted with the conditions furnishing immunity to the cellular tissue of the pelvis. All authorities agree in that simple uncomplicated pelvic cellulitis is a rare affection, many holding that it is only the result of uterine or ovarian disease, consequently only met with during menstrual life.

The best evidence one can adduce opposing this theory is reference to those cases of pelvic abscess found in childhood, two of which cases Emmet records.

The symptoms of long-standing parametritis in the adult are vague. In this child retention of urine seemed to be the only trouble. There was no fever indicative of the exudation until the night preceding the spontaneous opening of the abscess, showing that pelvic cellulitis may advance even to suppuration without causing any active disturbance.

Another point of interest in this case lies in the fact that after the evacuation of the pus through the unusually large opening the discharge ceased in a week's time.

The recovery was rapid, differing from the usual course of chronic cases of this disease, which do not terminate with the formation of abscess.

RICHARD DOUGLAS, M. D.

Nashville, Tenn.

Malignant Bilious Fever.

EDS. MED. AND SURG. REPORTER:—

In the last number (July 18) of your journal, you comment favorably upon a paper by Dr. R. Harvey Reed, of Mansfield, Ohio, on "Climatic Changes in Ohio," etc., an extract from which you publish.

Dr. Reed says: "These changes have been followed with a decrease in all forms of malarial diseases;" and you add, speaking of Illinois, where you collected observations twenty years ago: "The forms of malignant 'bilious fever' with which the old physicians had to combat are now scarcely met with. * * * The climate has been modified much, as in Ohio, the cause apparently being the more rapid surface drainage."

If Dr. Reed and you mean to be understood as contending that there has been "an alteration of type" in malarial diseases, as the result of climatic change, I take issue with you.

That "the forms of malignant 'bilious fever'" are now rarely met with is a fact which, I think, cannot be successfully denied; but that change or modification of climate has had a controlling agency in effecting the decrease, I seriously question—the apparent difference in the character of the diseases being due to difference in medical treatment. When, as was universally the case, about forty years ago—and is yet to some extent—bile was regarded as an excrementitious product, and "bilious fever" was believed to be caused by failure of the liver to secrete it in sufficient quantity or normal quality, and "cholagogues" and "alteratives" were freely used to "touch up" the delinquent organ, fevers ran an indefinite course, and, by the help of doctors, either killed the patient, or left him, at the end of from two to six weeks, a physical wreck.

Now, the physician is culpable who permits any case of malarial fever—except the pernicious or congestive type, and that only because the patient, from neglect, is usually almost moribund before the physician is called—to last over seventy-two hours at the longest.

To no one, perhaps, was the change of treatment presented in a more impressive manner than to myself. In the fall of '46, whilst a student in Georgia, my preceptor required me to watch all night the effect of one-grain doses of quinine upon an unusually vigorous man. The next summer I saw the late Dr. Jno. G. Gamble, of Tallahassee, Fla., administer ten-grain doses of quinine to a child of seven years. The child had been weeks under the care of two old physicians who were waiting for the fever to subside before giving quinine; Dr. Gamble gave the remedy during the fever, and arrested the disease in a few hours.

Last fall I saw a case of old-fashioned "bilious fever" in the person of a homœopathic physician who had been treated ten days by one of his professional ilk. Within twenty-four hours, under proper treatment, the doctor was convalescent. That case, under *laissez faire* treatment, showed that "bilious fever" now is just what it used to be. The result would have been the same if the old "heroic" treatment with drastic drugs, based upon an incorrect physiology and a false pathology, had been practiced. Give malarial fevers the chance they had in old times, and they will, in these days, show their former malignity.

GEO. TROUP MAXWELL, M. D.

Ocala, Fla.

NEWS AND MISCELLANY.

Proceedings of the Kentucky State Medical Association.

REPORTED BY ALLEN KELCH, M. D.

(*Continued from page* 111.)

Dr. J. A. Larrabee, Committee on Diseases of Children, after the usual introduction of papers spoke of

INFANT FEEDING AND CHOLERA INFANTUM

as follows:

The question of artificial feeding in infancy is one which should engage one's attention. The mortality among infants attempted to be reared independent of the mother is more appalling, and that despite every effort on the part of friends and nurses. In our institutions 70 to 80, and one report of Infants' Foundling Hospital, 90 per cent. of those taken from mothers early have been lost. In an institution of this kind in Louisville, where

mothers are taken with their babies and a gradual supplant of the breast is substituted, the mortality has not been over 5 per cent. from all causes, and would be even less but for the waifs that are left in excess of our ability to supply wet-nurses. Certainly the lesson here is plain. Mother's milk, as supplied from the mammary gland to the nursing infant, is the only food, and further, no perfect substitute has been, or ever will be, invented. A few years ago it would have been difficult to find food for infants for sale at any place. Now such preparations are beyond numbering, and are offered for sale at any well-regulated grocery, and the sale of these preparations is, I am told, an increasing feature of grocery as well as drug business. We are therefore constrained to ask wherefore the cause? The result is already shown, but wherefore this increasing demand? Can it be that our women are losing the beauty and loveliness of their maternity? Can it be that an assumed inability is made an excuse for a non-performance of duties which compromise the health of both the mother and her offspring? The spectacle of Russian prisoners leaving St. Petersburg every few days, banished to the cheerless wilds of a cruel Siberia, excites the sympathy of the civilized world. Not more surely and certainly do they commence the slow death than does the infant banished from the warm, genial breast of its mother, and condemned to travel the via dolorosa with a nursing bottle and the latest novelty of infant food for companions.

Good and sufficient reasons often exist for artificial feeding. Then the best substitute for mother's milk is that from the cow. The excess of casein and its difficult coagulability constitute its chief obstacle. Cows' milk coagulates in immense curds, while mother's milk is seen in light flocculi. This is really the only difficulty to overcome. A mechanical admixture of some granulated substance often answers. Many do well on condensed milk, which is simply milk from large dairies reduced to one-fifth its volume in vacuo, and sweetened, or claimed to be, with sugar of milk and not cane sugar. In large cities, where the milk-supply is poor and inadequate, it is a great blessing, and it may be fed without change (unavoidable in hot weather with cow's milk) into lactic acid. The addition of barley water to condensed milk, in quantity to make the required bulk for a feeding, meets several important indications. The introduction of digestive ferments has done much for these unfortunate infants, and a near approach to mother's milk has, by their addition, been already made.

There is one remaining consideration in the care and feeding of babies artificially, and, in the judgment of your committee, it has largely to do with the bad showing of infants' hospitals, as well as domestic practice. It is the fact that such infants are continually overfed. The estimate of the requisite quantity of healthy milk for a nursing infant is quoted often much higher than is true. The average amount of milk drawn from the mammæ, if a healthy mother, by a healthy infant at birth, is not over four tablespoonfuls, or an ounce and a half; this is, or should be, taken at first every two hours; later on, two ounces and three ounces may be supplied at intervals of three hours—and once at night—a part of this quantity being often regurgitated as superfluous. Compare this with the nursery bottle of artificial food as given every time the child cries, and we have sufficient cause for discomfort and disease. The infant actually grows poor with the labor of attempted digestion.

Cholera Infantum.—This disease is one that calls still more loudly for a correct etiology from the profession. The want is not likely to be filled by papers written upon summer diarrhœas, etc., so common in the journals of the day. Cholera infantum, if it means anything at all, means cholera in the infant, and is as totally distinct from diarrhœa or summer complaint. It is to be regretted that so much has been written upon the treatment of this disease, and so little learned as to its cause. Your committee is of the opinion that the investigation of the intestinal tract, and even the remarkable and recent developments of the microscope, will prove less advantageous in this field of etiology than the same careful investigation of atmospheric and telluric influences. The analogy between choleraic conditions and intermittent fever of pernicious type, and both these with the results of toxic doses of antimony salts, should invite attention to the influence of the supposed poison upon the nerve-centre, by which the sympathetic is paralyzed and the whole process of osmosis undergoes an immediate change. The disease is a neurosis, and is of the order of shock. The introduction of the term *thermal* in connection with some of the diarrhœas so alarmingly fatal in summer months, is correct, and carries the right meaning with it. It seems to be a modified form of sunstroke, in which the external temperature is greatly elevated, and attended by profuse watery discharges from the bowels. The treatment indicated by this view has proven its correctness, viz., the use of cool or cold-water sponging until the temperature is reduced and the diarrhœa controlled. A choleraic diarrhœa is also an accepted term, and applies to instances of putrefactive changes in the ingesta, when the term fermentation would mean more. This with inflammatory diarrhœa or dysentery always due to atmospheric influence, and rarely to ingesta, make up the combination of "summer" complaints so common at this season.

The treatment of cholera infantum must be prompt and well directed to be effectual, and when so applied your committee has found it to be attended by results far more favorable than at first anticipated.

We should no more place medicine in the infant's mouth to be introduced into the stomach, than we should think of attempting to stem the current of Niagara at Goat Island in a row-boat.

Hypodermic medication of the infant, with properly graded doses of morphia and atropia in cholera infantum, has, in the hands of your committee, been attended by such success as to warrant the recommendation. Many cases so treated were in the algid stages of cholera exhaustion. A single injection was sufficient to cause a halt in the osmosis, and a reflux of blood to the surface, and in most of the cases a single injection constituted the only treatment. For the choleraic or fermentative diarrhœa, with putrid odor of the discharges, the salicylate of lime in small and frequent doses has, in my hands, surpassed all

other treatment. This very common and easily recognized form of "summer complaint" yields readily to salicylates, either soda or chalk.

The treatment found most successful in inflammatory diarrhœas (infantile dysentery), has been to commence with saline evacuants, *e. g.*, Epsom or Crab Orchard salts or concentrated water in small doses given in comp. infusion of rosemary with a drop of laudanum.

Dr. Larrabee continued by a reference to the influence which the various cachexias exert upon the diseases of infancy in this connection, remarking that many a child whose disease has been correctly treated according to nomenclature, has ultimately been sacrificed because the underlying cachexia exerted its influence undetected.

Passing on to the fevers of childhood, they are characterized, said he, in many cases, by the rapidity with which they make their appearance, the unusual height which they reach, and their equally sudden decline.

A dose of castor oil is frequently all the medication required in many such cases.

The throat, said he, should always be examined as a routine matter in the fevers of childhood; for unless this is done sometimes days will elapse before the local mischief may be accidentally discovered, perhaps by some other than the attending physician, when the creamy deposit often noticed upon the tonsils suggests diphtheria, alarms the parents, and mortifies the doctor needlessly.

Passing on to croup and diphtheria, he regarded the diseases essentially and radically distinct. Diphtheritic-croup, typho-malarial fever, etc., said he, should be tied up in a bundle and consigned to the dark waters of oblivion. Croup, said he, is a local disease characterized by the production of a false membrane, which when removed is reproduced, and which tends by its obstruction to cause death by the obstruction which it produces to the function of respiration, while diphtheria is a disease producing its fatal result by exhaustion, offering no hope for relief except by constant alcoholic stimulation. He maintained that tracheotomy should be performed in croup early as a rule, and always whenever the respiration begins to grow embarrassed. In this connection he referred to a case upon which he operated the second day, the operation ending in apparent death, from which the child rallied and progressed favorably until the fourteenth day, when the tenacious discharges threatened to close the scene by obstructing the respiration. After the usual agents had been tried to overcome this trouble without availing, Labarraque's solution was adopted and fulfilled the indications; in seven days more the tube was removed, and the child is now well.

Whooping-cough, measles, and scarlet fever were simply referred to in the report.

The discussion of the paper, participated in by Drs. Scott, Hanwood, Thompson, and Bailey, evinced the usual variation of opinion and individual experience, with reference to the hypodermic medication of children with morphia.

Dr. Orpheus Everts, of College Hill, Ohio, by invitation, read a paper

ON OVERWORK AS RELATED TO INSANITY.

His apology for reading on this subject lay in the rapidly increasing public and professional interest in it. The etiology of insanity in general was then considered. But few persons, he said, are now brought to hospitals for treatment, who, if not too wild or too stupid to take notice of their surroundings, are not constantly assured by their friends that they have overworked, and must rest.

The subject was then systematized thus:

(*a*) What is work?

(*b*) What are the physiological relations of work to the organs and functions of the body?

(*c*) What are the pathological relations of work to living mechanisms and their manifestations?

Work limited to the performance of appropriate functions within the range of structural integrity is physiological in its relations to structure, but whenever not so limited, alternated by rest and compensated for expenditure of force by renewals, its relations to structure become pathological.

An exhausted brain, if exhausted by performance of its own functions, voluntarily or in response to its own necessities, will cease to perceive, remember, or think, and become unconscious during a period of rest and recuperation, if not whipped or spurred by undue influences.

After reporting several cases illustrative of the relation of insanity to overwork, the following conclusion was arrived at: While overwork, in its general sense, is a prominent factor in the problem of causation of diseases, some of which are manifested by mental disorder, overwork in the performance of mental functions is not a frequent or sole cause of such diseases.

FRIDAY MORNING.

Dr. J. G. Cecil read a paper on mastitis, in which he took the ground that all ordinary cases of abscess of the breast resulted from fissures and erosions of the nipple, and the methods usually adopted to relieve distention of the gland from the lacteal secretion. That nursing a breast by a child or other animal, or by using a breast-pump, when a fissure or erosion is present, will not only fail to give satisfaction as far as pertains to emptying the gland, but also prevents healing by the wound being continually torn open at each application. That accumulated milk is entirely innocuous to the gland and will not of itself cause abscess, and hence all attempts to remove the milk or reduce distension by rubbing, massage, etc., can only produce damage and cause the very trouble it is designed to prevent. Among the most important results of abscess is the probable relation of development of carcinoma in breasts where antecedent mastitis has existed. From the standpoint of the local origin of cancer, it is fair to presume that carcinoma is more likely to develop in breasts from scars and lumps left by inflammatory troubles than in breasts never the subject of these attacks. Deductions from figures given by Prof. S. W. Gross makes it appear that 8.21 per cent. of all child-bearing women have carcinoma of the mammary gland, and that 42.25 per cent. of cases of mastitis develop cancer.

Treatment recommended is that adopted by Dr. Philander Harris in *American Jour. Obstetrics* for January and February, 1885, namely, that of absolute non-interference with the lacteal secretion by any local application or by any methods of removing or checking the flow of milk, but the application of absorbent cotton to the glands, and

the application of a roller-bandage around the chest and over the shoulders. In multiple abscess the treatment of Billroth is advised—that of anæsthetizing patient, making a free opening with bistoury, then with finger break all the cavities into one and treat that antiseptically.

Dr. J. M. Ray, of Louisville, read a paper on

WOUNDS OF THE ANTERIOR SEGMENT OF THE EYEBALL.

He referred to the observation of DeMour, who in 1818 first noted that injuries of the anterior part of one eye are liable to excite inflammation in its fellow. Not till 1854, however, when Pritchard announced that enucleation of the wounded eye would mitigate or cure the sympathetic trouble if it had not advanced too far, did the suggestion become of any practical value.

Now the question most pertinent is, How much injury can the implicated eye sustain and be still retained with a minimum of risk to its uninjured fellow? It is likewise a most difficult question to decide. Where there is an extensive wound involving the so-called dangerous regions, and no perception of light remains, any surgeon would, on general principles, condemn the eye. There is danger, however, that some whose conservatism has given them bitter experiences of sympathetic ophthalmia, may advise the extirpation of an eye that by judicious care would become a useful organ.

Bowman has said that by careful nursing many eyes that are severely wounded can be saved from exciting sympathetic inflammation, even when there appears to be but little chance of obtaining a plump eyeball. The chief of the clinic of one of the most prominent British ophthalmogists, remarked, in answer to a query by the essayist, that "after a study of the subject for many years, and a careful examination of all the material afforded by the Moorefields Hospital, he had satisfied himself that many eyes were sacrificed which would by careful attention have become useful."

Two extreme cases were then related in justification of this conservative plan. In these, when any sign of impending inflammatory re-action appeared, 15 grains of calomel made a marked change, similarly to what is observed when destructive inflammation appears after cataract extraction. Two cases of wound of the ciliary region followed, in which, while the perception of the organ was not lost, its function was practically destroyed. These, under the use of atropia, bandage, low diet and rest, recovered. V=$\frac{20}{40}$ obtained in one case where the lens had undergone absorption, as the result of the injury by $\frac{1}{8}$.

In conclusion, the writer said: "The results obtained in the cases here reported are by no means observed in all injuries of the eyeball. Often an eye will react safely from an injury that threatened total destruction, and again an eye slightly injured will resent it very quickly. Especially in childhood is this often observed." He would therefore counsel a wise conservatism, never losing sight of the fact that if much inflammatory reaction takes place, if the ciliary region is involved in a firm cicatrix, the iris and ciliary body in a state of chronic excitement, with an abiding tenderness in the region, the eye should be carefully watched, and the patient warned of the dangers which menace the fellow eye from sympathy. The writer agreed with Swanzy, who says: "Never remove an injured eye unless it contains a foreign body which cannot be removed, if it has fair chance for sight, and there is no sign of inflammation; for the inflammation may not come on, and thus the eye be saved."

Dr. J. A. Stucky, of Lexington, reported on

ABDOMINAL INJURIES.

Case 1. Malinda J., colored, received a cut in abdomen, knife entering an inch to the left and below the umbilicus, penetrating the cavity. Wound three inches long. About two feet of intestines protruded; they were not injured. Patient placed under chloroform, intestines washed with listerine and water (1 to 12 parts) and gut replaced. Patient made rapid recovery, with no unfavorable symptoms. Treatment consisted of hypodermic of morphia $\frac{1}{4}$ gr., atropia $\frac{1}{150}$, to prevent the action of bowels, and prevent patient moving about in bed. Cloths wet with listerine and water were applied every four hours. Liquid food was given for ten days. Patient sat up on fifteenth day.

Case 2. Jno. Cleary, Irish, æt. 33, engaged in bar-room fight; received a cut in abdomen; on right side, extending from anterior superior spinous process to just over symphysis pubis, passing through abdominal parietes, peritoneum, and almost severing the small intestines in three places. Reached patient a few minutes after receiving the injury; found him lying on his back on floor of bar-room; the intestines protruded to the extent of six or eight feet, and were lying on the floor in a mass of blood, sawdust which covered the floor, and fecal matter. Had lost considerable blood; hemorrhage had ceased when I reached him. The wound was dressed as follows: Intestines were placed in basin of tepid carbolized water, and thoroughly washed; the abdominal cavity was sponged and cleansed as best we could under the circumstances, there having escaped into the cavity a quantity of blood and fecal matter.

The wounds in the intestines were closed with an uninterrupted suture of carbolized cat-gut. The intestines were put back irrespective of position, and external wound closed with an uninterrupted silk suture; adhesive (rubber) strip and a heavy abdominal bandage completed the dressing. Patient was removed to St. Joseph's Hospital.

Shock was great. Pulse quick and feeble. Stimulants were given per hypodermic with morphine and atropine, until patient rallied, which was about 12 hours after receiving injury.

Bowels restrained with opiates and same treatment followed as in Case 1.

Patient made a rapid recovery, nothing complicating the repairing of the wound. No peritonitis and little or no sloughing.

Bowels acted on 11th day. Patient sat up on 17th day, and was discharged four weeks after receiving the injury.

Case 3. Wm. Reed, Irish, æt. 28, brakesman. In making coupling of the engine to freight train, attempted to raise the draw-bar, so that the coupling-link could enter; while in the act, the engine pushed back, the link striking him, and entering

at a point about 2½ inches above the crest of the ileum, one inch to the left of the spinal column, and just below the last rib, passing directly through the abdominal cavity, the point coming out about 3½ inches above and one inch anterior to the ant. super. spine of the ileum. The muscles of the back and abdomen, as well as the peritoneum, were greatly lacerated. A close examination could detect no injury to intestines, or any of abdominal viscera.

Patient walked a distance of three car lengths, by holding one hand over injury in back, and the other hand over the abdominal injury; was placed in caboose and brought to Lexington, Ky., a distance of twenty-seven miles. His wounds were dressed at St. Joseph's Hospital, and examination showed that eight inches of gut protruded from wound in abdominal wall. This was replaced. The external wounds were closed by deep sutures of heavy silk. Recovery was complicated by circumscribed peritonitis—sloughing of both wounds. Treatment consisted of hypodermics of morph. and atrop., to relieve pain and control muscular action. Poultices to favor separation of slough, and liquid diet—milk and beef tea. After separation of slough, the wounds were filled with iodoform, edges brought together by long strip of rubber adhesive plaster, and covered with carbolized oakum, and abdominal bandage. Enema of soap-suds given on 9th day, when bowels acted freely.

Seven weeks after injury, patient exhibited to Kentucky State Medical Society. Wound healed rapidly by granulation. Patient sat up on 18th day.

Dr. W. O. Roberts, of Louisville, read a paper on

DIRECT HERNIOTOMY,

reporting several cases.

In case 1 the hernia had existed from boyhood, the patient being now thirty-five years of age. Until the last year a truss had been sufficient for relief. Since, a suspensory bandage had been worn, and at the time of operation, the tumor, gradually enlarging, had reached the size of a goose-egg. In this case, before opening the sac, the enteric or reducible portion of the tumor was returned. The adherent and irreducible portion was found to be composed entirely of omentum, and was fully as large as a man's hand, much thickened, and attached to the sac by strong adhesions. A ligature of whale tendon was thrown around it at a point just within the external ring, and the part external to the ligature cut away. The sac was now dissected up, and a ligature applied external to that on the omentum. The body of the sac was then removed, and the *pillows* of the external ring secured in apposition by a continued suture of whale tendon. The wound was closed by deep and superficial sutures, and a compress and bandage applied. The only antiseptic used was a weak solution of carbolic acid. But slight shock followed the operation, and recovery occurred without an untoward symptom.

In the second, a case of strangulated hernia, the patient persistently objected to an operation until fæcal vomiting had occurred for eight hours, when his pulse was 108, temperature 100° F., expression anxious. On opening the sac, a dark-reddish fluid escaped.

The hernia was an entero-epiplocele. The intestinal portion was very deeply congested, while the omental portion was gangrenous. I ligated the latter at a healthy point, and cut away the dead portion. The intestine was now thoroughly cleansed, and reduced without difficulty. The sac was then dissected up and divided at its neck, a drainage-tube introduced well up into the canal, and the external ring closed around it. The patient rallied from the operation, had two actions from his bowels in the afternoon. But on the following day general peritonitis set in, which ended fatally on the third day. No post-mortem could be obtained.

In another, the case of a man 62 years of age, where the hernia had existed for twenty years, unmistakable signs of obstruction manifested themselves, and on operating the sac was found very greatly thickened, and its upper and lower part separated by a small cavity, which contained about a dram of pus. The hernial tumor tightly filled the inguinal canal. It did not extend beyond the external ring. The index finger, inserted into the ring and carried gently along the canal, soon effected reduction. I soon dissected up the sac, and threw a silk ligature around it, just within the external ring, and cut away that portion which lay in front; I then twisted the neck upon itself several times, closed the ring with the continued suture, and the wound with deep and superficial sutures, and over all applied a compress and bandage. Carbolized silk was used for ligatures and sutures, and a one-in-two-thousand solution of corrosive sublimate for hands, instrument, etc. Outside of a rather sharp inflammation of the scrotum, recovery was fairly quick and wholly uninterrupted. Six months have now elapsed since the operation was done, and though the patient has worn no truss the tumor shows no disposition to return.

In a case of a woman 65 years of age, in whom the hernia had existed for 32 years, strangulation occurring, operative procedures were instituted, when, said the speaker, "I found the sac deeply congested. On being opened, a small quantity of straw-colored fluid escaped. The contents of the sac consisted of two knuckles of intestines, the surfaces of which were covered with lymph. After dividing the stricture, the protruded bowel was thoroughly cleansed and replaced. As the sac showed such slight signs of vitality it was not further disturbed. The upper two-thirds of the wound in the superficial tissues were brought together, a drainage-tube introduced through the lower angle up to the femoral ring, and a compress and bandage applied. The antiseptic used was bichloride of mercury 1 to 2000. This dressing remained undisturbed until the fourth day, when upon its removal the upper two-thirds of the wound was found well united. Considerable discharges had passed through and around the tube, and the sloughy sac protruded through the opening. On the seventh day it came away. There was no peritonitis, and the patient's temperature at no time reached 100° F. A voluntary action of the bowels occurred on the fifth day. The entire wound healed in four weeks, when the patient left the bed. She

neglected to wear a truss, and in two weeks after the hernia recurred. The patient was able to return it without difficulty, however, and she now keeps it in place without difficulty by a truss."

The speaker then entered upon a comparison of various operations, the result of which had led him to prefer that practiced by Mr. Hardie.

Dr. P. S. Connor, of Cincinnati, read by invitation a paper on

FRACTURE OF THE NECK OF THE FEMUR.

After referring to the acrimonious and bitter discussions that have occurred from time to time in medical literature, and after calling attention to the anatomical conditions influencing the repair of fractures in this locality, the speaker in reference to treatment said: "The weight and extension dressing, which answers so well in fractures of the shaft, when applied to those of the neck proves defective in so far as it permits of considerable movement at the seat of injury, does not control the outward displacement of the upper end of the lower fragment, and fails in the very essential requisite of any suitable fracture dressing, that it shall altogether prevent or reduce to a minimum movement of the joints immediately above and below the line of break. And, further, it does not and can not keep the fragments in fixed relation to each other when movements of the trunk or limb are made; so that if changes of position of the body are effected, as they must and will be, more or less disturbance of the fragments must result.

"The immovable dressing, to fully satisfy the requirements of the case, must embrace not only the thigh, but the pelvis, or at least the half of it, in order that the hip-joint may be fixed, and the action of the hip-muscles restrained as far as possible. And just here lies the difficulty in the application of such dressings, and the imperfection of it as generally seen. From below the level of the great trochanter the plaster-of-paris bandage (and this is of course, for many reasons, the best of the immovable dressings), can be easily put on, care being taken to properly cut it out and protect it on the inner side so that no undue pressure shall be made upon the region of the genito-crural furrow, and that urine-soiling shall not occur. But to carry it up to and over the iliac crest and inward to the ischial tuberosity—in other words, to apply it over the whole gluteal region, and hold it there—requires an additional girdling of the upper part of the opposite half of the pelvis or the carrying of the supporting dressing obliquely around the body across the opposite lumbar region. Unless this is done, no matter how closely applied at first, in a few hours, or at most days, the dressing will be found to have sprung off, and to be no longer exerting due pressure upon the hip muscles; as the result of which the motion of the joint will be little or not at all controlled, probably no more so than if the bandage had only been carried up over the trochanter major. Even if the immovable dressing has been properly applied and well maintained in position, there is always a chance that in consequence of wasting of the limb sufficient loosening may take place to permit of some displacement of the fragments, to prevent which the weight and extension treatment may be very profitably combined with the fixed dressing.

"Applied early, the immovable dressing saves the patient much suffering, and permits with safety, so far as the fracture is concerned, of such changes of position as will not only greatly add to comfort, but materially lessen the chances of the development of that hypostatic pneumonia which is so often the direct cause of death.

"The more experience I have had of this method of treating neck fractures, the more convinced I have become that by careful application of it we can secure better results with less trouble to our patients and to ourselves than in any other way; and I feel confident that in a large proportion of cases recovery will take place with a limb of good functional value.

"Perhaps in the future it will be clearly shown that the rare occurrence of bony union in the past, has been simply because the fragments of the broken femoral neck have not been kept steadily in apposition, but have, by the permitted motion of the hip-joint and the unrestrained muscular action upon the shaft, been allowed to so separate and play upon each other, that only an imperfect ligamentous repair has been possible."

The Cholera in Spain.

The correspondent of the *Brit. Med. Jour.*, July 11, writes from Valencia: The cholera has spread rapidly in this city and province in the last week, and has equally increased in fatal intensity. It has now entered the upper and mercantile classes, and in numbers of cases its work has been sudden, sharp, and short. People of all ages are cut down in from 4 to 12 hours; and if they survive 36 or 40 hours, by far the majority of these recover. The only sheet-anchor of treatment that I hear of is "laudano de Sidenham" and the disinfectants, crude phenic acid and chloride of lime, called here "polvos de gas." In the suburbs of this city, the places most severely scourged are the Grao or harbor of Valencia and Cabañal. These are both two miles from this, to which runs a tramway every 8 or 10 minutes. They also join on to each other. The latter is the great seabathing quarter of the Valencianos; and at the former there are large floating baths. Both localities are without a shadow of drainage; all the filth and garbage of the houses are thrown into the streets, and when a fall of rain occurs (which has been the case since my last letter), the black stinking mud and filthiness are indescribable. All the houses are damp and offensive and dark. There could not be a better breeding-ground for any kind of zymotic germs. The inhabitants are fishermen of the dirtiest type, harbor-laborers, with a sprinkling of store-keepers. The disease has been most virulent in the Cabañal, and, the Cholera Hospital has been full to overflowing, as also the one at the Grao.

I am sorry indeed to state that some of our countrymen have been cut off in the last three or four days. Captain Nicol (of Glasgow, whom I knew), of the steam-dredger España, going on shore, was seized in the street, where he fell down attacked, and was allowed to remain there three hours, although people were passing, when

one of the men from the dredger saw him, and dragged him to the hospital, where he was denied admittance. He was then taken to an empty schoolroom, where he died, thirty hours later, and was buried in the common grave. The cook of the steamship Ross also died in a few hours; also a Norwegian; and yesterday a young English man, whose parents live here and are iron-founders. He was cut off in twenty hours.

The death-rate to-day shows for this city and province 783 attacks and 412 deaths, which is a fearful increase since my last notice. I told you the troops were then all right. Within the last two days the Colonel and also the Commandant of the regiment "Biscaya" have fallen victims, and 12 or 14 of their men. We have in this city 8,000 troops of all arms, and I am told to-day that the bulk of the men have orders to disperse to their homes. The municipality have been compelled to hire all the men that offer to guard the houses, that is to see that that they are isolated, as their staff of police was not sufficient for the duty. The disease is assuming a fearful aspect among asylums of various kinds, and also in the schools and colleges in and about this city. To-day I see it has broken out in the Orphan Asylum of the San Vicente Ferrer (the patron saint of Valencia), which is a large establishment for the education of boys. The panic in this city is simply indescribable. People are afraid to go out into the streets, and the better class simply shut themselves up in their houses, and will neither take in their accustomed newspaper, nor allow the word "cholera" to be uttered. People are still fleeing north, and the Barcelona train is crowded daily with the panic-stricken. I know two men who, after they were inoculated, fled from their houses, leaving their wives and children. In the city and province of Murcia, matters are equally bad, if not worse; but what surprises me much is, that cholera has taken a sudden leap into the Royal summer quarters of Aranjuez, attacking yesterday 201 and killing 70. A very few days of such work will kill every one in the place. King Alfonso, without leave, made his escape to the place, to visit the sick, returning the same day, and has got his ministers into a broil for allowing him to do so.

I had a letter from an old friend, surgeon to the Lead Mining Company in Linares, Andalusia, who informs me as yet no case has occurred there, and that Cordova and Seville are also free as yet.

I dare say, by the time this reaches you, you will have the details of the falling through of, or the sudden return of, the French Commission sent here to study and examine into Dr. Ferrán's cholera-inoculation, the chief being Dr. Brouardel. They left this suddenly the day before yesterday. I believe they expected to be here a month. The Ferránist paper, *Las Provincias*, gives as the reason for their hurried departure that Dr. Ferrán refused to let them into the secret of how he attenuates his cultures for inoculation. Its adversaries state that the Commission found nothing to study worthy of science, and left in disgust. Since Dr. Ferrán has again been permitted to inoculate, large numbers crowded his place for two or three days. I expect to see, in a short time, the whole so-called "grand discovery" exploded, seeing that both the inoculated and re-inoculated send their quota of victims to the cemetery. As yet, not one word do we hear of a case in Cataluña. What and when the end of this invasion will be, God only knows! If it is so very bad now, at the beginning of the hot season, none can foretell what it may be by the middle of August.

A DECREE gazetted Paris, July 8th, requires any person receiving a traveler from Spain, to notify the fact to the municipality. Posts of observation are also to be created near Toulouse, Foix, and Perpignan.

The Cholera Inoculations.

The *Lancet*, under date of July 11, tells us that although Dr. Ferrán, with the sanction of his Government, continues to prosecute his inoculations of cholera virus, and doubtless to reap a rich harvest from those who can afford to pay him, the medical world has received but little satisfactory evidence of the really prophylactic nature of the proceeding. It appears that a single inoculation is not so certain to ensure immunity as a second one, and that is said to afford absolute immunity for about a year; but, so far as we can gather, there is no evidence for this latter assertion. Indeed, as the practice has only been in force for a few months, it is impossible that its efficacy can have been so tested. The Spanish Commissioners regarded the subject as one worthy of further trial, but came to no conclusion as to its value. The Belgian Commission, upon which Dr. Van Ermengen is serving, has not yet reported. Of the French Commission, Dr. Brouardel has returned to France because he has been refused permission by Dr. Ferrán to examine his samples of cholera lymph or to assist at the inoculation experiments; and Dr. Gibier reports that the preparation and nature of Ferrán's vaccine liquid remains a close secret. He was allowed, however, to witness the inoculation and to examine the "lymph," in which he found comma bacilli. Dr. Gibier no more believes in the protective influence of these inoculations than he would in the power of inoculation with catarrhal products to prevent a violent cold. We are at a loss to understand the refusal of Dr. Ferrán to inform these gentlemen of the precise nature of his inoculation fluid. It is singular, to say the least, that he should have invited inquiry, and then have declined to furnish those who are sent to investigate with full details of the process. Such a course will go far to throw discredit on the whole proceeding, and serve to confirm previous notions as to the improbability of any useful end being obtained from it. It is melancholy to learn from Dr. Gibier that the filth of the Spanish hospitals and improvised infirmaries is inconceivable to one used to French establishments of the same kind. No wonder that he "never saw cholera in a more terrible form" than he there witnessed. And yet faith in protective inoculation grows apace! What is this but a grasping at the shadow of prophylaxis, and taking no heed of the real substance. More lives are being sacrificed by the neglect of sanitary laws than could be saved by inoculation, even if it were as efficacious as it is claimed to be; and nothing can excuse such neglect, which would not be tolerated in any other country.

Arsenic in Burial Soil.

A foreign exchange tells us that a paper which may have some bearing on hygienic as well as on forensic matters, was attributed to the Académie des Sciences by MM. Schlagdenhauffen and Garnier (*L'Union Médicale*, June 20.) The observations made during the past three years by these authors have led them to some interesting conclusions. Arsenic was found to be disseminated in variable, and often in considerable, quantities in the different soils of the Vosges; the red sand appeared to be the richest in this mineral. Burial-places in such localities are thus made in arsenical soil. Arsenic in these soils probably exists in the form of arseniate of iron, which is but little soluble in boiling water, and altogether resists the action of water at the ordinary temperature, whilst it cannot be taken up by rain-water permeating the soil. Arsenic in aqueous solution, in almost any form, left in contact with a ferruginous clay and chalk soil, in the laboratory, is gradually transformed at the ordinary temperature into insoluble derivatives, which are retained by the earth; this transformation is accelerated by the heat of the sand-bath. Any compound preparation of arsenic, even very soluble ones, like arsenate of potassium, introduced into a natural soil of the ferruginous clay and chalk sort, and submittted to the action of rain-water at the temperature of the different seasons of the year, behaves in the same manner in the laboratory, in contact with a soil of the same nature and with an excess of water. If the preparation is insoluble, it remains so; whilst, if it be soluble, it slowly becomes insoluble. and at such a rate that at a depth of .60 to .9 metre beneath the level at which it was placed, no trace of it can be recognized at the end of fourteen months. The results thus obtained are corroborative of those made by Orfila, in 1847, in connection with the Nicolas Noble affair, and prove satisfactorily that arsenic cannot be taken up by the subsoil water, and thus brought into contact with a corpse buried in an arsenical soil.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended July 11, 1885.

Fessenden, C. S. D., Surgeon. Leave of absence extended sixteen days, on account of sickness. July 1 and 9, 1885.

Bennett, P. H., Assistant Surgeon. Granted leave of absence for twenty-two days. July 9, 1885.

Items.

—The Dutch Sanitary Commission has tested the bread from two bread factories, and from 55 or 60 bakers, for alum and sulphate of copper, with the result that the bread from the factories was free from alum, but that a fourth part of the bakers used more or less of it. This general result is published by the Commission as a warning to the bakers, it being intimated that if they are found to continue their adulteration, their names will be published.

—Oleum deeilinæ, or deelina oil, is the name given by Dr. John Roberts, of Chester, England, to a refined petroleum, prepared on the banks of the Dee, and which is recommended for medicinal and surgical use, on account of its greater purity than vaseline. Although it is an oil, little or no greasiness is left on its application; it is readily absorbed, has no odor, and never becomes rancid. Dr. Roberts regards it as "almost a specific" in eczema and kindred diseases of the skin.

—The *Canada Medical and Surgical Journal* says that a lady in a leading town in the Dominion consulted an itinerant professor of medicine regarding her defective vision. She paid her $1 entrance fee to the show for the privilege of speaking to the "Doctor." He informed her she was rapidly losing her sight, but showed her a little bottle which he said would positively cure her. Price only $10. This staggered her. She immediately resolved to "go it blind."

—A case, which well exemplifies the advisability of medical men viewing the body before giving a certificate of the cause of death, is reported from England. A man, named William Mellor, lately perpetrated a most curious imposition. Having been ill and attended by a medical man, he, upon recovery, shaved off his whiskers and beard, and otherwise so altered his appearance, as to induce the surgeon to believe that he was William Mellor's brother, and that the sick man was dead. Having obtained a certificate, he registered his own death, and drew the burial money from a Foresters' lodge. Upon the discovery of the fraud, he decamped.

—G. Bunge, in the *Zeit. Physiol. Chem.*, describes experiments on the form in which iron exists in egg yelk. He is led to believe that food does not contain iron in inorganic combinations, but that it only exists in complex organic compounds which have been formed by the vital processes. It is absorbed and assimilated in this form, and then converted into hæmoglobin. This is, he is aware, apparently at variance with the observations of practical physicians. The apparent contradiction may, he thinks, be explained by the hypothesis that inorganic iron salts prevent the decomposition of the organic iron compounds in the intestinal canal.

—J. C. Ugaz, writing in the *Cronica Médica* of Lima, calls attention to the vesicating property of the inner bark of the walnut tree. He cut a square of about two inches each way, stripped off the outer bark, macerated it in vinegar for a quarter of an hour, and applied it to his arm on going to bed. He was disturbed in his sleep by the discomfort produced, but, wishing to carry out the experiment, controlled himself. After about an hour he awoke in severe pain, and tore off the bandage and piece of bark. In the morning there was no pain, but three large blisters filled with serum and covered with a blackened skin had appeared. The writer also applied the bark to the lip of a boy suffering from hypertrophic lupus, and dusted the blister with calomel. He did not see the boy for eighteen days, and when the latter returned he was completely cured. Señor Ugaz asks, "Can walnut and calomel be specifics for lupus?"

EMMET'S OPERATION—WHEN SHALL IT AND WHEN SHALL IT NOT BE PERFORMED?*

BY E. G. ZINKE, M. D.,

Of Cincinnati, Ohio.

Trachelorraphy, or Emmet's operation for the cure of laceratio cervicis uteri, and its consequences, though recognized by many in this country as a measure productive of much good, is slow in receiving acceptance with gynecologists abroad. The injury is readily diagnosed, and its evil results easily appreciated. What treatment could be more reasonable, more rational, more simple, more effective? In my judgment, there is but one point left to be discussed. This point is embodied in the title of this paper. I have addressed to a large number of the most prominent American and foreign gynecologists the following series of questions, taking care to appeal to those known to be opposed to the operation, as well as those favoring it:

First Question.—Do you believe lacerations of the cervix uteri to be an important factor in uterine and pelvic disease?

Twenty-two out of thirty-four answer with an unqualified affirmative, while some modify their assertion by saying, "most emphatically, especially if there be some eversion," or "subinvolution," or "chronic congestion," or "when extensively lacerated," or "only when a persistent focus of irritation," etc. Only one replied "no."

Second Question.—Do you believe fissures of the cervix uteri a cause of uterine or pelvic disease?

The majority answer, "sometimes;" eleven, "yes;" seven, "rarely;" two, "if deep;" four do not answer at all, and three, "no."

Third Question.—State your theory in what manner a lacerated cervix will or may cause disease of the uterus, its surrounding tissues, and in parts remote.

The substance of these answers is as follows:

1. Septic poisoning at the time of its occurrence.
2. It causes pelvic cellulitis.
3. It causes pelvic peritonitis.
4. It prevents involution.
5. It acts as a point of irritation.
6. It causes pelvic congestion.
7. It causes cervical and corporeal endometritis.
8. It causes profuse leucorrhœal discharge.
9. It causes displacements of the uterus.
10. It causes erosions and eversion.
11. It causes hyperæmia of cervix as well as body.
12. It causes hyperplasia of cervix as well as body.
13. It causes cystic degeneration.
14. It causes numerous reflex symptoms, especially from irritating cicatricial contraction.
15. It causes menorrhagia.
16. It causes sterility by preventing conception and causing abortion.
18. It lays the foundation for epithelioma.

Fourth Question.—Do you believe laceration of the cervix a cause of sterility?

Seventeen answered "yes," and three "no," while others qualified an affirmative reply by saying "if extensive," "sometimes," "if there is

* Abstract of a paper read by E. G. Zinke, M. D., of Cincinnati, before the American Medical Association, May 1, 1885.

profuse catarrh or cicatricial contraction of the canal," etc.

Fifth Question.—Do you believe that Emmet's operation, if performed early and properly, will, to some extent or entirely, prevent uterine and pelvic disease?

Twenty answer affirmatively, one "it may do immense good," and several "to a great extent," "in well-chosen cases," or "if existing complications have to a great extent been cured by preparatory treatment." Only one gives a positive "no."

Sixth Question.—Do you believe that Emmet's operation is absolutely necessary in certain cases? If so, specify the class of cases?

The sum of the replies to this is, that the operation should be carefully and perfectly performed—

1. When pathological changes exist which depend on the laceration, and which cannot be disposed of by other treatment.

2. When the laceration is deep, bilateral, or stellate, with a history of cancer even before secondary changes occur.

3. When in advanced age it prevents senile involution.

4. When subinvolution and cervical disease exists.

5. Where there are large gaping rents.

6. Where there is villous degeneration of the endometrium.

7. In menorrhagia.

8. In habitual abortion.

9. To lessen the danger of cancer after the child-bearing period.

10. Where there is cicatricial tissue in the rents, causing reflex symptoms.

Seventh Question.—Do you believe every lacerated, not fissured, cervix, will cause eventually uterine and pelvic disease?

The greater number answered "no," or "not necessarily;" a few believed that the majority of the lacerations will. One states that "some escape by reason of unimpaired ligaments," and another that "some will heal over and never produce any symptoms whatever." Some said "only when extensive," and only two answered "yes."

Eighth Question.—If not, state approximately how many such cases you have observed?

Five answered, "quite a number, but by far the minority;" not a few have "kept no statistics, but have seen quite a number;" three "never;" one "six;" two "100 or more;" one "about 40;" one "over 50;" one says "impossible to do so;" four do not answer, and one "has seen many hundreds."

Ninth Question.—State approximately, or exactly if you can, how many times you have performed the operation?

Many have not the figures at hand, nor can they obtain them. Two, Byford, of Chicago, and Taylor, of Cincinnati, fail to report; but the number of operations made by Emmet, Thomas, Lyman, Byford, and Taylor, is estimated at about 1500 cases.

Engleman, G. T. (about 40 to 50)	45 cases.
Jackson, A. Reeves, about	200 "
Wilson, Ellwood, exactly	128 "
Wilson, C. M., "	12 "
Nash, H. M., about	22 "
Sutton, R. S., "	100 "
Munde, P. F., "	200 "
Van der Warker, Ely, about	120 "
Johnson, Jos. Taber, "	30 "
Hunter, J. B., at least	200 "
Prince, David, about (6 to 8)	7 "
King, Willis P., exactly	7 "
Palmer, C. D. (35 to 40)	37 "
Goodell, Wm., exactly	263 "
Mann, Matthew D.	90 "
Baker, Wm. H., about	400 "
Jenks, E. W., "	200 "
Reamy, Thad. A., exactly	324 "
Harvey, T. A.	200 "
Murphy, P. J., about	50 "
Byrne, J., "	200 "
Lusk, W. T., "	300 "
Chrobok "	10 "
Howard, W. T., "	100 "
Wylie, W. Gill, "	200 "
Barbour, A. H. T.	
Duncan, J. Matthews	

Total No. operations, 30; cases, 4,945

Question 9a.—How often for the restoration of the cervix simply?

Nine answered "never;" one, "often as a prevention;" one, "three times;" one, "one time;" one, "25 times;" one, "50 times;" one, "one time after delivery, for hemorrhage from the circular artery." Six do not answer the question at all, and others, from various reasons, cannot state how many times.

Question 9b.—How often for the relief of pathological changes and reflex disturbances depending thereon?

Drs. Emmet and Thomas have both confessed that to-day they do not operate as frequently as formerly.

Tenth Question.—What have been your immediate results respecting union and relief?

Most of them answer, "good;" one "had four failures to unite;" one "failed to get union occasionally in his early practice;" another had failure of union in five operations; one had always a good result where the cicatricial tissue was removed thoroughly; one had five failures in

two hundred cases. In one instance death occurred from septo-pyæmia, and in one from phlebitis.

Eleventh Question.—What have been your remote results respecting union, relief, and sterility?

One answers, Pregnancy occurred in twenty cases.

One answers, Pregnancy occurred in five cases.

One answers, Pregnancy occurred in twenty-five cases.

One answers, Pregnancy occurred in some cases.

One answers, Believe it cures instead of causing sterility.

One answers, Twelve confinements out of one hundred and twenty-eight cases, one twice, with recurrence of the tear.

One answers, Sterility cured in small number.

One answers, Conception frequently followed.

One answers, Relieved large number of sterility.

One answers, Conception usually followed successful operation.

One answers, Not positive.

One answers, Highly satisfactory.

One answers, Impossible to say.

One answers, Very generally good.

One answers, Good.

One answers, Largely beneficial.

One answers, Cannot say.

One answers, Good in early failure in old cases.

One answers, Remote results better than immediate.

One answers, Excellent; conception quickly followed.

One answers, Saw ten cases in which sterility lasting several years seemed to have been cured.

One answers, Good.

One answers, Not been able to follow all my cases; some have become pregnant.

One answers, Relieved a large number of sterility.

One answers, Two out of my seven cases have again borne children.

One answers, Sterility cured in a small number.

One answers, Cannot state definitely.

One answers, Good in overcoming sterility.

One answers, Good so far as a check upon tendency to abort.

Two say, "Unable to answer."

Twelfth Question.—When, in your opinion, is Emmet's operation contra-indicated?

The answers to this may be summed up as follows:

1. In acute or sub-acute inflammations.
2. In pelvic cellulitis.
3. In pelvic peritonitis.
4. In lymphadenitis.
5. When ovaries and tubes are diseased.
6. When the uterus is very irritable.
7. Never the rent *eo ipso*.
8. Pregnancy.
9. Menopause, if no eversion or hypertrophy exist.
10. Manifest hydro- or pyo salphynx.
11. When there is no ectropion.
12. When there are no nabothian bodies apparent.
13. When there are no symptoms of uterine origin.
14. Not needed in limited lacerations or fissures.
15. When local treatment gives relief.
16. When peri-uterine adhesions exist.
17. When uterus is immobile.
18. When there is neither eversion, local congestion, or reflex disturbance.
19. When there is cancer of the neck or body of the uterus.
20. When patient is suffering from pulmonary consumption or other grave malady.

Operations may be divided into three classes. Those who advocate operative interference in every lacerated cervix; those who do not endorse the operation at all; and those who deem it a necessity in some "well-selected cases" only.

That the operation is too often performed, that cases are operated upon in which no indications for it exist, that as a consequence the results looked for are not obtained, that the patients, so far from being relieved, are subjected unnecessarily to procedures not free from danger, and occasionally followed by unfavorable results, rendering the patient worse instead of better, is the opinion of many.

If a lacerated cervix is the cause of all the ills the text-books and authors attribute to it, then every rent in that portion of the womb ought to be sewed up.

We are compelled to admit that it is not true that every tear in the cervix is productive of evil, and that it is not good practice to stitch up every os simply and solely because it has sustained a slit; nor is it fair to assume that because certain diseased conditions co-exist in, around, or near the cervix or the uterus and its appendages an operation is necessary to a cure. I have arrived at the following conclusions:

1. It is evident that the operation has been performed unnecessarily for symptoms similar to,

but other than those arising from lacerations of the cervix; further, that it has been done imperfectly, even without preliminary treatment, in many more; and the failure to give relief, as reported by several, is due to these two causes.

2. That from our present knowledge we cannot at this time arrive at any definite conclusion, from the fact that many of the so-called consequences of laceration of the cervix uteri are not settled beyond doubt.

3. That every one engaged in this department should carefully select his cases, and try every known means to give relief before recourse is had to operation.

4. The operation should never be performed *eo ipso* in cases of simple fissures or lacerations of first and second degree.

5. In cases of eversion and disease of the cervical and corporeal cavity, or both, although attended by hyperplasia and displacement, it has sometimes been observed that all the symptoms abated, that all the parts returned to their natural condition, and that no laceration was discoverable after the employment of alleviative measures alone.

6. That there are some cases of extensive lacerations of the cervix that seldom give rise to any inconvenience, and that, therefore, an operation should be deferred until symptoms arise that will call for its performance.

7. The operation, although indicated, should never be performed until, by preparatory treatment, the parts have been brought as far as possible into a healthy condition.

8. Near, and during, the climacteric period, the operation should be postponed as long as possible and the patient not be exposed to any risks, since in many cases all the symptoms subside under proper treatment and never return, on account of senile involution.

9. The operation is justifiable in cases of lacerations of the third and fourth degree, without complications, if there is a history of malignant disease in the family.

10. The operation may be performed with perfect propriety in young women as a preventative, if the laceration is bilateral and extends up to the cervico-vaginal junction or beyond it, even though there are no pathological changes; indeed, it seems to be the duty of every one who observes a lesion to that extent to urge an operation.

11. The operation is justifiable in any degree of laceration, and in rare instances, even in fissures, when there exists cicatricial tissue productive of reflex disturbances, annoying in character, and not tractable under any other treatment.

12. The operation is absolutely indicated in all extensive tears of the os, in which the cervix is everted, its mucous membrane and nabothian follicles diseased, and especially if there be granular or cystic degeneration present, provided the parts have first been restored to a healthy condition by palliative treatment.

METRORRHAGIA.

BY JAMES E. FREE, M. D.,
Of Emporium, Pa.

Metrorrhagia is a common disease in females, dependent upon morbid conditions which produce hemorrhage from the endometrium. Transient causes make most women liable to slight attacks occasionally, and spontaneous recovery is the rule; but sometimes the bloody discharge through the vagina becomes a source of weakness to both body and mind, and treatment prompt and effectual is demanded.

The loss of blood may be trivial, but the knowledge of even the slightest degree of flooding is sufficient to make a patient nervous and uneasy. Women will worry and fret about a few stains until they actually are bedfast, and it stands to reason that the amount of blood lost was not enough to account for the systemic depression often observed.

D. W. Cathell, M. D., of Baltimore, in his little volume entitled "*The Physician Himself*," urges the importance of treating the whole individual, and not merely his actual diseases. His ideas seem to us to be strong, for if we waited to administer drugs until sufficient reason existed for their employment, we would miss more than one opportunity of increasing our reputation and multiplying our influence. Women who are persuaded that they have a disease peculiar to their sex will say little in praise of the physician who attempts to gainsay them; what some seem to expect is a confirmation of their own diagnosis, and woe be to the one who refuses their reasonable request. It will do for the hoary-headed practitioner to turn up his nose at the whims of a lady patient, but the royal road to practice for the young man is to cultivate her good-will at all hazards. And there is no reason why a patient should not receive a prescription to soothe an agitated mind, provided the perturbation is strong enough to interfere with the healthy functions of any organ or set of organs. The best way to act in emergencies is to say little and give less medicine, largely diluted.

Confidence is a wonderful restorer; next to

balmy sleep, it is tired nature's best friend; and whosoever has not had occasion to be profoundly thankful for the manifestation of this virtue in his patients, is not competent to speak on this subject. Suspicious patients who have no faith in drugs and doctors do not long trouble us; it is our friend who has implicit confidence in our skill, who catches at the straws we throw, to save himself from imaginary evils.

One of the commonest causes for metrorrhagia is exercise after child-birth. Subinvolution succeeds indiscreet conduct very often at this critical period, and the train of symptoms is as familiar as an old friend's face. Swelling, tenderness, pain in the pelvis and back, hemorrhage from the uterus, and jaundice, etc., etc., *ad infinitum*.

In such a case, the first thing to be done is to obtain rest. Our old professor of gynæcology at the College of Physicians and Surgeons, Baltimore, used to repeat this injunction over and over, "*Remove the cause*," until the student who did not have at least one safe answer for some of his examination questions was in danger of hell-fire, to speak metaphorically. His rule works out in practice admirably, and in following his advice, and making a searching investigation into our cases, we have frequently stumbled upon discoveries.

All sorts and sizes of doses may be prescribed without attention to this cardinal point, and disheartening failure be still inevitable. Success is bought with a price. We are not justified in expecting to obtain the therapeutic effect ascribed to a remedy by the Materia Medica, without due regard to the conditions making it possible. When a course of treatment is adopted, with a medicine bearing a good reputation, the physician's judgment and the patient's common sense are at stake with it. A horse cannot trot against time with a weight on his back; neither can metrorrhagia be cured sometimes unless due regard is paid to surrounding circumstances.

If these two important considerations are attended to, namely, rest and the exciting cause, half the battle is won; as soon as the roots of a tree are cut the trunk and branches wither, and if we are able to dam the fountain, the stream soon runs dry.

Nothing is so inspiriting to a patient as to realize that the physician has a system about his management of the case in hand, and very few will remain intractable when they are given to understand that they must bear a share of the responsibility. It is well nigh impossible to get a sick person's mind off her disease for any length of time, but it is possible to rouse a sluggish imagination by giving them something to do which will appear to have a direct bearing on their case, and such a consummation is devoutly to be wished.

The physician who makes a clear diagnosis of metrorrhagia and at the same time recognizes the valuable assistance which rest is ready to lend him, besides seeing the cause for the disturbance of the uterine functions, is most likely to have at his command the means to accomplish a cure.

One of the most useful medicines in metrorrhagia is bromide of potash. None of the bright and shining lights of the profession have recommended its use so far as we know, but great men are not always discoverers; they sometimes swell to immense proportions on borrowed fame. Nothing is surer than the therapeusis of bromide of potash and ergot in cases where some of the trouble arises from a strained condition of the sensorium. Ergot of course is our sheet-anchor, but it is not always the *sine qua non*.

We have before now succeeded in relieving a patient of a profuse hemorrhage by the use of morphia and bromide of potash: an overshadowing symptom in this case was cephalalgia, which yielded nicely in a few hours and was shortly afterwards followed by the disappearance of the metrorrhagia, but worse than either was the itching eruption which appeared and obstinately hung on for a month.

Neither ergot nor the bromides should be used for any length of time, on account of their well-known effect. It is our firm belief that more than one idiot in our asylums has been brought to his low estate through the use of this drug by the advice of medical men. An epileptic in this town has used a New York alienist's prescription for several years which contains several drams of the bromide daily, and each time he visits his adviser the dose is increased.

Gallic acid in combination with ergot is also reliable in metrorrhagia, but one objection, and a powerful one by the way, is its disagreeable taste. One of our patients took one teaspoonful, threw her bottle away, and recovered promptly. No better astringent can be found than gallic acid in some cases of hemorrhage. Last spring, we encountered a case of hemophilia, which baffled every combination of medicines suggested by several physicians, and finally was cured by forty grain doses of gallic acid. Viburnum has healing in its wings sometimes, but it is such a vile-smelling compound that we have abandoned its use wherever practicable. Quinine, ergotin, and ferri sulph. exsiccat. with gentian, makes an ex-

cellent formula for pills to be used in metrorrhagia.

A RARE COMPLICATION AFTER OVARIOTOMY.*

BY C. D. PALMER, M. D.,

Professor of Gynæcology, Medical College of Ohio, Cincinnati, Ohio.

The speaker commenced by saying that details of the ordinary run of cases are now no new story. There occur, however, occasionally, unheard-of complications. These, for the better guidance of the surgeon and the perfection of the literature, should be not only mentioned, but recorded. With this object in view, he presents the following case:

Miss ——, German descent, blonde, delicate organization. Noticed at the age of nineteen an abdominal tumor. This was three years ago. The tumor was central, regular, and uniform. A few months later, she consulted two physicians, who diagnosed Bright's disease, and tapped her. The abdomen completely collapsed. The process repeated itself, when the same diagnosis was made at one of our hospitals. She was again tapped, with the same results. She was again tapped for the third time. At each of these tappings one and one-half bucketfuls were removed. The tappings were continued until eight in number, extending over a period of seventeen months. The fluid was at no time especially thick. Her last attendant, Dr. John Kellar, suspecting the true state might not be that of ascites, requested the author to see the case with him. The abdomen was found to be immensely distended. Fluctuation distinct, superficial, and uniform. There was also dullness extending backwards to an unusual degree. Lateral decubitus showed a slight change in the area of dullness. No fluctuation could be felt in the posterior cul-de-sac. Patient anæmic and feeble. Pulse 120–130 per minute. Evening exacerbation of temperature. Menses absent for six months. The lower extremities œdematous and swollen, but no albumen in the urine. From these facts the diagnosis was made out to be ovarian cyst of the unilocular variety. In view, however, of the former diagnosis, and the fact that there were some obscure points in the history and physical signs, an exploratory incision was made. This confirmed the diagnosis. The general condition was the most unpromising for an ovariotomy. The hygienic surroundings were also bad. The abdominal wall being opened, the cyst wall was found closely adherent in all directions to the abdominal parietes. When these adhesions were broken up as far as the finger could reach, a large amount of fluid began to flow through the abdominal opening. The source of this was found to be two lacerations, which entered the interior of the cyst. This opening was directly opposite to a cicatrix in the abdominal wall, and had been made by the repeated tappings. Through this some cystic fluid had doubtless flowed into the peritoneal cavity after some of these tappings, but subsequently its edges had been agglutinated by peritoneal adhesions to the abdominal walls. Two other smaller openings were also found. they were clamped with hemostatic forceps and the larger plugged by the large-sized ovariotomy trocar, through which the cyst was drained. This was almost completed before it was attempted to detach the cyst from the surroundings. The adhesions were short, thick, firm, numerous, and universal over the whole anterior and lateral abdominal walls, omentum, lower border of the stomach, and to a limited extent to the colon. They were broken up by steady traction on the cyst, dissecting with the handle of the scalpel. The pedicle attached to the right ovary was treated with transfixion with very strong, yet soft, carbolized silk, each section tied separately, and the entire stump tied by an additional wrapping. It was then cut off about one inch from the seat of ligation; after which a wedge-shaped section was cut out of the fore end and the peritoneal edges sewed together by a continuous stitch of catgut. The author practiced this method of dealing with the pedicle in his last five ovariotomies, all of which have proved successful. It is a method which possesses special advantages against secondary hemorrhage and septic poisoning. Oozing was controlled by hot-water sponging and the application of the thermocautery. The peritoneal cavity was cleansed of all blood, ascitic and cystic fluids by means of fresh, very soft carbolized sponges wrung out of hot water. The abdominal cavity was closed with silk sutures without drainage-tube. Hypodermics of brandy during the operation and brandy after it were made. The operation left the patient in a forlorn condition, but she improved during the day. All food was given per rectum for the first week. A low form of peritonitis commenced on the third day. It was attended with tympanitis and dyspnœa. Pulse 140, temperature 103°–104° F. This condition things continued for one week.

* Abstract of a paper read before the Ohio State Medical Society.

On the eighth day a fatal termination from septic poisoning seemed inevitable. The abdomen was opened by removing two stitches, and a rubber tube inserted, evacuating 8 to 10 ounces of fetid serum. The peritoneum was then washed out with weak carbolized warm water. Temperature fell 3° in two hours, and all other bad symptoms improved accordingly. These washings were continued for three days. The patient improved very much. Convalescence seemed established, and recovery seemed certain, when yet another complication appeared.

On the twelfth day a smell of gas with fecal odor was noticed at the opening made into the abdominal cavity. The next morning a small amount of fæcal matter was seen and removed. A fæcal fistula had formed. It seemed to communicate inwardly with the lower small intestine, while the external opening presented on the median line midway between the umbilicus and the symphysis pubis. At first it discharged daily several ounces of liquid fæcal matter, and has continued to discharge since in quantities gradually diminishing and offensiveness growing less. The present quantity averages daily about two or three teaspoonfuls. The patient has readily improved, though convalescence was impeded by old stubborn diarrhœa and bronchial catarrh. Phthisis was feared for a time, but for two months recovery has been complete, except for the fæcal fistula. It is possible that in the course of time this fistula may close spontaneously. No treatment for the fistula has been made except the regulation of the diet and the application of a firm compress. Surgical interference may yet be needful. This occurrence is of interest and rarity. It is still a question as to how and when it occurred. Although ovarian cystic tumors may, by perforation of their walls and those of the intestine or stomach, discharge themselves into these cavities, there was no evidence that such was the state of affairs in this case. No one suspected that the intestine was injured at the time of the operation. These organs rested in their normal position, and on account of the great abdominal distension were compressed into the smallest space. The fæcal fistula appeared on the twelfth day after the operation, and four days after the abdominal cavity had been opened for drainage, and one day after the discontinuance of the intra-peritoneal injection. The most reasonable and plausible explanation would be that the intestinal perforation resulted from softening, from the peritonitis taking place from without inwardly. It is certainly fortunate that the peritoneal cavity was opened when it was. The septic fluid remaining would certainly have led to a fatal issue, and it was well to afford an exit for the fæcal matter.

Baker Brown, in his "Ovarian Dropsy," gives examples for the various avenues for the escape of ovarian cystic fluid.

Instances of fæcal fistula after ovariotomy are related by Milner Moore (*Lancet*, p. 329, vol. i., 1880,) and Bantock (*Lancet*, p. 207, vol. i., 1879). Atlee, Peaslee, Simpson, Barnes, Thomas, Emmet, Goodell, and Tait, make no mention of any case. Spencer Wells refers to three cases, one of his own. This was the only one in his 1,000 ovariotomies. Mr. Bryant (*Guy's Hospital Reports*, 3d series, vol. xiv., p. 228,) reports an interesting case. These and other cases influenced Spencer Wells to make use of the extra-peritoneal method of dealing with the pedicle. Pauchin and Kuffrauth (*Belgian Med. Press*, 1880, xxxi., p. 217), and Kusswein (*Centralblatt für Chirurgie*, 1879, p. 630,) report cases.

It is remarkable that such perforations do not occur more frequently. The same may also be said of lacerations of the intestinal tube. The tumor is often adherent to the parts, and is separated from them with the greatest patience and skill. Bantock and Barnes (*Lancet*, 1877, vol. ii., p. 312) mention cases of this kind. Considering the facts, is it not possible that lacerations and perforations are accidents more common than supposed?

A REMARKABLE CASE.—THE IMPORTANCE OF EXPLORATORY INCISIONS.

BY R. STANSBURY SUTTON, M. D., LL. D.,
Of Pittsburgh, Pa.

My rule of practice, with very few exceptions, has recently been to open the abdomen of every woman giving assent, when there was good reason to believe that the ovaries were unsound. In one case, a few months ago, I hesitated, for I thought that treatment might relieve the symptoms. This patient was spayed soon afterwards by my friend, Dr. Hunter, of the Woman's Hospital, New York, and the result was diseased ovaries. We are more likely, if careful, to err in not spaying than in spaying many doubtful cases. Exploratory incisions under proper precautions are almost absolutely safe, and there are many cases in which it is not possible to make a diagnosis without the incision. It does not require much diagnostic skill to say that abdominal section should be practiced in cases where the symptoms are patent, *but no man living can always tell*

when and why this or that woman should be spayed to cure her of her mysterious malady. A safe operation and a safe place will simplify matters immensely if exploratory incision is resorted to. I never yet lost a woman from exploratory incision.

On May 7, 1885, Mrs. L., aged forty years, in very feeble health, was sent to me by Dr. Cook, of McDonald, Pa., for a lacerated cervix operation. Her youngest child, of which she had five, was five years old. Since weaning that child she had been a confirmed invalid. She had been treated by many physicians, in and out of private institutions, for womb disease, and no good came of it. She was very anæmic, walked with difficulty, and complained of pain in her left leg. Her courses were regular and not painful. Her nervousness was intense. On digital examination, the cervix was found lacerated on both sides. When she was brought fully under the anæsthetic, I found, by bimanual palpation, an ovary slightly enlarged and slightly prolapsed. I supposed it to be the right one. On the left side I thought I could detect the outline of the left ovary. Former experience and observations made at the side of Mr. Lawson Tait's operating table, told me that this was a case for the removal of the ovaries. Its sequel will prove that such cases should be, at least for some time to come, referred to specialstis. No speculum was introduced. The examination over, I wrote Dr. Cook, a most accomplished physician, that a lacerated cervix operation would not benefit the patient—that she must be spayed before relief would follow. He visited her and saw her with me here; and after further examination, coincided with me in regard to the operation. She returned home a few days later.

On June 8, nearly a month later, she returned, and was admitted to my private hospital for women. On June 10, in the presence of Dr. Cook and Dr. John P. Sterritt, I spayed her, taking both ovaries. My regular assistant, Dr. Stone, being absent, Dr. Cook assisted me. The operation lasted ten minutes; five minutes later the wound, 2½ inches long, was closed with six silk-worm gut sutures. Her recovery was rapid, she was up and about on the twelfth day. Her highest temperature was 100°, six hours after operation; the next day it was 99°; on the fifth day it was normal. Her pulse never reached 100 while on her back.

CONDITION OF THE OVARIES.

The right ovary was the size of a black walnut, and contained a roll of blonde hair, liquid fat, and a half tooth, the tooth as if cut in its long axis, the nerve cavity well formed

The left ovary was not quite as large, and contained three cysts filled with fluid; a fourth cyst burst as I drew the ovary up between my fingers.

My diagnosis was one, and probably two, diseased ovaries. I did not know what the disease was. It was not necessary to know that to decide upon the proper treatment. The result bore out the wisdom of the advice and operation. In this day of advanced knowledge it is most unscientific for a general surgeon to stand up before an audience of intelligent medical men and say, "*I would always prefer to send my patients to a surgeon who could make a diagnosis without an exploratory incision.*"

An exact diagnosis of the disease in these ovaries was impossible. This was my thirty-fourth abdominal section, the one hundred and fifty-sixth I have witnessed. It was the twenty-first done in my private hospital in the twenty-one months it has been open. It was the eleventh ovariotomy, of whom ten have recovered and one died. Four times I have opened the abdomen in patients upon whose abdomens I never laid a finger until they were etherized and the abdomen was laid bare for operation. They had large growths; pregnancy was easily excluded; their countenances bore the diagnosis of ovarian cystomata as distinctly as the title of a book tells you the subject treated of. These patients all recovered. Timidity on the part of the patient is important; frighten her, and she may die. A slight examination just before cutting will, if pregnancy is excluded, often set a skillful man right; if it does not, exploratory incision will. Hours spent over the diagnosis of many abdominal tumors are to the patient trying; the impressions they leave may after operatien prove fatal. With too much handling cysts may, indeed often have, burst in the hands of the examiner. Professor von Billroth said to me on one occasion: "I formerly made much of the diagnosis; I don't care so much about it now before opening the abdomen."

Medical Societies.

PHILADELPHIA NEUROLOGICAL SOCIETY.

A stated meeting was held April 27, 1885. The Vice-President, Dr. Chas. K. Mills, in the chair.

Dr. Wharton Sinkler presented a patient suffering from what he thought might be called Friedrich's disease. Although differing from this affection in some respects, the main features are like it. He read the following history of the case:

Mary G., aged eleven years, eldest of five chil-

dren; the others are all healthy, and have had no nervous diseases. The parents are healthy, and neither they nor any ancestors they know of have had nervous affections or phthisis. Mary has had no other illness except measles, which she had since the present trouble began. About October, 1882, the mother noticed that her hands were unsteady and that she dropped things; that she walked awkwardly, and often stumbled and fell. Her general health has remained good, but the incoördination of movement has steadily grown worse. At no time has there been pain of any kind in the limbs or body; no attacks of gastric disturbance, and no disorder of the bladder or rectum.

Present Condition.—It will be observed that in standing there is a swaying to and fro of the body, and that this is increased if the patient closes her eyes; apparently she would fall if she did not open the eyes. The movements of the hands seem awkward and badly directed, but she can execute most movements.

The nutrition of the legs is good; in fact, they seemed so stout and hard that when first I saw the patient I suspected that it was a case of pseudo hypertrophic paralysis. She has, however, no loss of power, and can rise from a recumbent position on the floor with ease. The skin of the legs seems thicker than usual and closely adherent to the subjacent cellular tissue.

Sensation is undisturbed, and there is no analgesia.

The patella reflex is absent. Papillary reflexes fairly good.

Electrical Condition.—Examination by Dr. G. Betton Massey. To the faradic current the muscles of the legs and thighs respond normally. The response to the galvanic current is lessened quantitatively, but great pain is caused by this current. Speech is unaffected, and the intelligence is fairly good.

Dr. A. J. Parker demonstrated a Chinese brain.

CHICAGO MEDICAL SOCIETY.

Stated meeting, July 6, 1885. The first vice-president, C. W. Purdy, M. D., in the chair.

Dr. Robert Tilley exhibited to the society microscopical specimens of the fungus aspergillus glaucus, taken from the human ear, an osteoma developed from the crusta petrosa of a canine tooth, and filaments, or mycelia, from the body of a tonsil.

While exhibiting the specimens, Dr. Tilley as follows:

"In describing to you the three specimens which are exhibited under the microscope, I will refer in the first place to the fungus—aspergillus glaucus—taken from the human ear. I have had this in my possession for three years, and have shown it to several of my acquaintances, but did not deem it of sufficient interest to exhibit it before. It is, however, an object which many have not seen before, although it is mentioned in every text-book on the subject. I have no intention whatever of entering into the question of the aspergilli in general relative to their influence when found in the ear. But I must say that my experience relative to the question leads me to think that its influence as a source of pain in the external ear is greatly exaggerated in the books. This specimen was taken from the posterior wall of the meatus of a little girl who had for some time previously been afflicted with otorrhœa. The otorrhœa had however ceased, and the fungi were readily recognized in lusty growth immediately on looking into the ear. There was, however, no pain complained of; the patient was brought rather for inspection than for the expectation of relief. You will observe that the fungi are growing on what by simple inspection might be called dry but otherwise normal wax. You will notice that the fungus consists of one straight long stem surmounted by a round ball, very much like the top of an onion which has run to seed. It is commonly said, I think rather on theory than on observation, that they are caused by sleeping in low, damp apartments. The child from whom this was taken belonged to people in good circumstances, and was well taken care of, and was not living in damp quarters.

"The next specimen, to which I will now refer, is the osteoma developed from the cementum or crusta petrosa of a canine tooth. I am very sorry that I cannot give you anything of the clinical history, because I believe it would be interesting, if known. In consequence of this, it is perhaps necessary that I should give a word of explanation as to how it came into my hands. A friend was speaking to me of some one who had been subjected to the operation of drilling through the fangs of six teeth, on account of what was called 'ossification of the nerve.' In speaking to one of my acquaintances among the dentists about such a condition, I was presented with a tooth, a section of which I exhibit to you. You will see, both macroscopically as well as microscopically, that the line of demarcation is well defined. You will further see that the general appearance of the tumor is that of bone, and that it differs greatly from the general appearance of the tooth proper. It is interesting to observe, moreover, that the canal, through which the nerve and vessels enter, is greatly diminished in its course through the tumor, consequently great pressure must have been exerted on the nerve. Before making the section, I had supposed that the canal was completely obliterated, so small is its opening at the end of the tumor. On looking at the specimen through the microscope, you will see very clearly that while the line of demarcation between the dentine and the proliferation of the crusta petrosa is well marked, and the lacunæ and canaliculæ of the bony structure of the tumor are well demonstrated, there are also a number of contorted tubules in the bony tumor, which resemble somewhat the dental tubules. Haversian canals are of course not present; they never are in such growths.

"Although I have no clinical history to present, I may add that the usual clinical history is one of severe pain, which nothing but extraction seems capable of relieving. The last specimen is one which I obtained from one of those little pockets which are often found in the tonsils. They seem to come and go, sometimes without giving any more inconvenience than a little discomfort. They are frequently associated with fœtid breath, and in some cases the masses themselves are very offensive (in odor). In the present case,

however, this was not so, there was no fœtor. There was, however, an unpleasant sensation amounting to a positive discomfort running down the neck externally, in the direction of the sterno-cleido-mastoid (muscle). On pressure around the base, the little mass popped out, suddenly, so that it came near going down the patient's throat. In examining it, under the microscope, it proved to be one mass of filaments, very fine, and containg spores in the body of the filaments, and associated with fat crystals.

"I succeeded in staining them with methyl violet, but only after first extracting the fat with ether.

"I have no theory to present, gentlemen; I simply exhibit to you what has been interesting to me. After the removal of the small mass I did not think any treatment was necessary; but as there was a little bridge of tissue more or less dividing the cavity into two sections, I divided the bridge with the electro-cautery."

The Treatment of Acute Coryza

was the subject of a paper by Dr. J. A. Robinson. He said the literature on the subject of the treatment of acute coryza is scanty and of a stereotyped nature. The profession seems to have arrived at two conclusions; first, that it is not a disease of sufficient severity and importance to command especial attention; second, that no plan of abortive or curative treatment has been sufficiently successful to cause them to investigate the subject further. However, in view of the fact that repeated attacks of acute coryza undoubtedly have a causal relation to pathological changes in the nares which it is difficult to remove, and that we are so frequently consulted by public speakers and singers who beseech us to abort or rapidly cure such acute attacks, it certainly deserves more than a passing notice.

The time-honored plan of aborting an acute coryza by the administration of a full dose of opium, an active purge, and a potent diaphoretic, has proven more disagreeable than efficacious. The plan, advocated by Dr. Ferrier, of blowing into the anterior nares a powder composed of morphia, bismuth and acacia, has been quite satisfactory in a few instances, but it is not free from the objection that, when successful, it often produces an unpleasant nausea. Its success is undoubtedly due to the sedative and astringent effect upon the inflamed mucous membrane.

What are the pathological conditions in the first stage of acute coryza? Briefly, there is dilatation of the capillary vessels, the arterioles being dilated and the venules engorged, inducing tumefaction of the mucous membrane. This is accompanied by dryness and pain. Secretion is abolished. In reflecting upon these circumstances the thought naturally arises, whether, if we can employ such measures or drugs as will antagonize these abnormal states, we will succeed in aborting the disease. We have recently had added to our armamentarium a drug which more completely antagonizes in its physiological actions those pathological conditions than any other. It is the hydrochlorate of cocaine.

Its physiological actions have been demonstrated to be concisely as follows: when applied to a mucous membrane it is a potent although transient anæsthetic, a vaso-motor constrictor, causing contraction of the arterioles and depletion of the venules, thus rapidly emptying congested tissues of a surplus of blood. This drug is also an astringent and has the property of lessening the secretion of muciparous glands. On studying the relation between the state of the nasal mucous membrane in the first stage of acute inflammation, and after an application of cocaine, the theory was formulated that cocaine should prove useful in aborting acute coryza, and it was determined to try it on the first opportunity.

The details of the first experiment are as follows:

Miss S——, a soprano singer in one of our city churches, applied to me on the morning of February 22, and desired immediate relief from a "cold in the head." She complained that the previous night she had been exposed to a draft and awoke that morning with the cold, as evidenced by the fact that she could not breathe through the nose, and that her nose felt dry and painful, and she had lost the sense of smell. Inasmuch as she had to sing that night at a special service, she must have immediate relief.

Upon examination I found all the conditions incident to the incipiency of an acute coryza. Her temperature was 102° F., with some acceleration of the pulse.

Febrifuges and a mild diaphoretic were prescribed. A local application of a four per cent. solution of hydrochlorate of cocaine was applied, as thoroughly as possible, to the congested mucous membrane, and the parts were sprayed, also, for some time with a warm alkaline spray, hoping thereby to reduce the hyperæmia. After having made another application of the cocaine, the patient was instructed to return home and follow the same line of treatment and to return the following day. She did not return until three days later, when she reported, to my surprise and gratification, that she had been able to sing as desired, and that no symptoms of the disease had returned.

The success which attended this new departure, induced me to try it in other cases of acute coryza which were seen early, and it has almost always been successful. Of course, the number of cases which we see in their forming stage are few, on account of the fact that the patients do not seek medical advice for this affection until the disease is well advanced.

In the use of cocaine for the purpose of aborting an acute coryza there are some objections; it has to be applied often in order to maintain its action on the inflamed mucous membrane, and it is an expensive drug. I have found that the use of a warm alkaline spray serves to prolong the sedative action of the cocaine.

Of course dependence is not to be placed on local measures alone, but in addition proper attention is to be given to constitutional and hygenic treatment.

Dr. Tilley said he had used the hydrochlorate of cocaine in two or three cases of acute coryza with much satisfaction. According to one patient, an attack had ended with a single application. While he did not look upon cocaine as a sure cure for acute coryza, he thought it almost always did good. He referred to a serious accident which

occurred to one of his patients during the use of cocaine. The patient was a boy aged twelve years, in whose nose a little cocaine had been used. After the first application he suffered a little nausea, which was not regarded as serious; after the second application the nausea was worse, but it was not until a third application had been made that the symptoms became alarming. These symptoms were difficulty of breathing, syncope, irregular action of the heart, cold perspiration and loss of sensation in the extremities. Notwithstanding these symptoms were alarming, the boy recovered quite rapidly. He had noticed reports of cases in the journals where the same symptoms had appeared.

Dr. Weller said that he had had a good deal of experience in the use of coca, especially in the form of the fluid extract. He had taken large doses; in his own case he had used two pounds in a short time. Formerly he had considered it as harmless as tea, but latterly he had arrived at the conclusion that it is a powerful narcotic. The strange phenomena which follow use of cocaine in some cases, he believes to be due to the narcotic action of the drug, and that they would no appear if the drug was not given in large doses. He believed some patients to be peculiarly susceptible to the action of coca or cocaine, similar to the idiosyncrasies of patients in the use of belladonna, opium, and alcohol. In the case mentioned, he believed the symptoms to have been the result of an overdose of cocaine. In his experience, he had found a two per cent. solution of cocaine strong enough, and urged the tentative use of the drug in the same manner as in the use of morphia.

Dr. Webster did not wish to be considered skeptical, but he had some doubt as to the alarming symptoms in the cases mentioned having been due to the drug. Is it not possible they were the result of reflex processes in over-sensitive patients? He had a patient recently who vomited after holding a fever thermometer under her tongue.

Dr. Paoli believed that the old treatment of acute coryza by giving the patient a hot bath, muriate of ammonia internally, and inhalations of camphor in hot water, or the oil of eucalpytus, combined with borax, was the best, although he would acknowledge that cocaine would often relieve severe attacks in a short time.

Dr. S. J. Jones asked the author of the paper if he had used cocaine with a steam atomizer in acute pharyngitis, tonsillitis, and laryngitis; also, if the applications of cocaine to different patients were from the same solutions, and at brief intervals, so as to be able to state how a reliable solution acted on different patients.

Dr. Robinson, in closing the discussion, said he did not advocate the plan of treatment as infallible or free from objections, nor did he neglect to use other means of cure if he thought they were advisable. As to the effect of cocaine on certain patients, he had similar experience to Dr. Tilley in the case of a woman who had twice been operated on without cocaine for nasal polyps. No unfavorable symptoms occurred during these operations. At the third and fourth operations cocaine was used, and the patient was troubled with nausea, vomiting, palpitation of the heart, and syncope. As no cocaine had been used in the first two operations, these symptoms in the third and fourth operations seemed to be, undoubtedly, due to an idiosyncrasy of the patient. He had not used cocaine with the steam atomizer, but he thought it feasible if the drug were not so expensive. He prepares fresh solutions for each patient, so as to preclude all possibility of failure of action by reason of deterioration of the solution by age. He had found the same package of cocaine to vary in its local and constitutional effect on different patients, affecting some more rapidly and profoundly than others.

Society then adjourned.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Relations of Skin Diseases to Marriage.

Dr. A. H. Ohmann-Dumesnil thus writes in the *St. Louis Med. and Surg. Jour.:*

Marriage and syphilis has been so thoroughly discussed and so much attention has been paid to it, not only by syphilographers, but by the profession in general, that all the phases of the question have been considered. Despite this, all authorities are by no means united in their conclusions, although all agree that, during certain stages of the disease, marriage is entirely precluded. That syphilis is hereditary and transmissible is acknowledged by all who have had any experience whatever in the observation and treatment of the disease. Those physicians who have paid any considerable attention to insanity and affections of the nervous system, claim for many forms of the neuroses, if not a direct transmission, at least a hereditary tendency to the same or allied forms of nervous lesions, derived from one or both parents. Rheumatism, gout, hemophilia, phthisis, and a number of other general affections, are accused by a number of experienced writers to have that power in them by which the patient will hand down the peculiar susceptibility to those diseases to his unlucky progeny. On the other hand, some very respectable authorities deny heredity as such, while acknowledging that the physical weakness is perpetuated.

A few of the more common, and at the same time most troublesome diseases of the skin will be briefly noticed in this paper, and an atttempt made to point out the probable chance of their reappearing in the offspring, together with the reasons why patients suffering from certain dermatoses should, if not entirely give up marriage, at least postpone that relation until circumstances justify such a course. As a prefatory remark it

may be stated that it is not necessary for the mother or father to be the recipient of the trouble from the consort in order that the child may be the subject of the disease.

It is not the local manifestations of the disease that constitute the active factor, but rather the general condition of the entire economy of one of the progenitors, which has undergone certain more or less profound changes which manifest themselves more or less distinctly upon the external surface of the body, as a sort of danger signal; and, generally, there are certain appearances connected with these lesions that, to him who can read, constitute a fair index of the severity of the existing condition.

It is manifestly obvious that a person suffering from an infectious or contagious disease should not marry during the active period of the trouble. No one afflicted with any one of the parasitic diseases would object to submitting to a proper course of treatment before marrying. But there are some troubles of the skin which, although we may admit that they are neither contagious nor directly transmissible, or only rarely so, are sufficiently dangerous, in this respect, to awaken our attention and deserve more study. It will be noted that the extreme views of the French and German schools of dermatology have been avoided, as we are not willing to admit, on the one hand, the universal constitutional nature of all dermatic affections; nor will we, on the other, concede that they are all purely local and due, almost without exception, to external causes alone. For this reason, whatever authorities we have consulted are chiefly those occupying what we consider the most rational position, which is one situated midway between the two extremes, and from those who are willing to let theory bend to facts.

The object of these few remarks is not so much to uphold a theory as to inquire whether there may not be enough in the question of the heredity of skin diseases or the predisposition thereto, to make it of some moment to the medical practitioner who may be questioned as to such being a bar to marriage.

Eczema is by far the most common, and, unfortunately, it often becomes the most intractable of the troubles afflicting the skin. When first studied, the disease was for a long time regarded as purely local; then it was admitted by a large number that it might be somewhat dependent upon internal causes. Its heredity was denied *in toto* at first. We find that, later on, in speaking of the etiology of this protean disease some authors acknowledge having seen a few—a very few—cases which they considered hereditary. The latest work on the subject, and one which we, as Americans, are proud to point to, is Bulkley's sterling work. He says*: "But, on the other hand, although the disease appears to come by direct inheritance in but few cases, it is still true that in a certain number it is seen to be hereditary, and whole families are sometimes affected, not only in one generation but in several." . . . Again, "Scrofula or struma undoubtedly appears as a predisposing cause of eczema in the way of inheritance, quite as affectually as when existing in the individual." Van Harlingen, Piffard, Liveing, Duhring, E. Wilson, and even Neumann, acknowledge that, in some cases, the disease is undoubtedly hereditary. There is also a greater probability of its being transmitted if it exists as an old, chronic, and intractable form of the disease in the parent.

The next most common affection which we meet with in practice is, no doubt, psoriasis. This disease is acknowledged by all authors of any prominence to be hereditary. It is contended, however, by a number of recent observers that the heredity is more marked, or more liable to be seen, if one or both parents have had the disease in a marked and recurrent form. In those cases in which it assumes the "universal" form, it is pretty certain that the offspring of the affected parent will either exhibit the same disease or some allied cutaneous affection.

Lupus vulgaris, whose pathology is as yet involved in more or less obscurity, is another one of those dermatic affections which would seem to be transmitted from parent to child. We will not inquire whether the neoplasm which constitutes it is scrofulous, tubercular, or of some other origin. Any one of these causes is sufficiently impressed upon the constitution of the progenitor to involve that of the progeny by direct inheritance.

Ichthyosis, espscially of that variety known as "ichthyosis hystrix," is undoubtedly an hereditary affection, or, rather, deformity. There is no single author who has ever observed any number of cases, limited though it be, who has not immediately had his attention called to this important fact. It would be useless here to advert to the *dicta* of the many dermatologists who have expressed an opinion upon the subject. The disease is undoubtedly the most markedly hereditary one with which we are acquainted.

Lepra, or true leprosy, whether it be dependent upon a bacillus or not, is transmissible from parent to child. Although no well-authenticated cases exist to show that it has been acquired by contagion, or that its bacillus has been successfully inoculated, examples of its occurrence in families which have continued leprous for several generations are numerous and well attested. Whether the primary cause be climatic or parasitic, the fact of its heredity remains.

Chronic pruritus has been observed in a mother, her daughter and granddaughter, as detailed in the *Journal of Cutaneous and Venereal Diseases*, February, 1885, by Dr. Wm. J. Maynard. An interesting fact in connection with this is that the male members escaped.

Sarcoma and carcinoma of the skin are further examples—of a malignant type of disease—of dermatoses which are transmissible from generation to generation.

The writer has observed cases of vitiligo in which the trouble was transmitted to the offspring apparently. Not only was there a reappearance of the disease in the children, but all were affected in a manner similar to that of the parent, and identical parts were the first to be involved in the process.

We know well that the color of the skin is very susceptible of being transmitted to the children, and we daily observe such as the result of

*Second edition, p. 93.

mixed intercourse. Each race has certain pigmentary peculiarities of the skin, which, by some process or other, seem to be stamped upon the child to a greater or less degree. In certain families we find that a lock of white hair in a particular locality is transmitted from generation to generation, just as other peculiarities or deformities are. Often, again, whole generations escape, and the "sign" reappears upon a remote descendant, showing that although this peculiar force may become latent, it does not necessarily lose any of its strength on that account, as all those acquainted with the facts of atavism know.

A cursory glance at these various examples would seem to indicate that heredity plays a very unimportant part in the genesis of skin diseases. But when we take into consideration the small amount of care taken, not only to trace diseases back to their origin, but also the inability to follow the various successions through different generations, the amount of evidence offered acquires more force than would be at first accorded to it. Besides this, the cause can often be recognized as being some condition which has shown itself in different ways, and only evidence itself as a skin disease in the last member of a long line of individuals. Were our observers to pay more attention to this subject, there is no doubt whatever that the *role* played by heredity would be found to be much more important than it is regarded at the present time.

As a natural conclusion, it will follow that, if certain skin diseases are directly transmissible, or if the causes thereof are, marriage between individuals affected with these troubles, whether the disease be confined to one or both of the high contracting parties, should be very carefully considered, if not prohibited. Before permitting such an union to take place, the dermatic genealogy should be carefully examined, and all the possibilities conscientiously weighed. The intention of this paper is rather to call attention to a few isolated facts, and to direct observation to a new point in connection with the etiology of skin diseases, which may prove serviceable in the prevention of a number of the most intractable and chronic affections which afflict the human skin. There is no doubt whatever that the more these relations are sought after the more often will they be found, and enable the physician to give safe and reliable advice in those cases where it will be needed or sought.

Sterility in Man After Syphilis.

Dr. Edm. Goldman thus writes in the *Texas Courier-Record of Medicine*, February, 1885:

During my sojourn in Mexico I had the opportunity of making some observations concerning syphilis, which I did not find in the other parts of the world, where I have practiced or studied, and among these, one of more than ordinary interest, the one to which I wish to devote the following remarks—namely, sterility in man after and in consequence of syphilis.

The strangest part of my observation, however, is this, that I have met with this constitutional defect only in men of the Caucasian race, who were at one time infected by Mexican women of the Indian type. Syphilis in a Mexican of the Indian or mixed race is quite a different affection, as to its violence of character and length of duration, from what it is if transplanted, so to say, upon a foreign soil.

My attention was called to this years ago by that excellent authority, Dr. Fred. Herff, of San Antonio, and I have found it confirmed in all cases that came under my treatment. I have witnessed rigors of such a severe order before the appearance of the macular eruption, that they resembled the algid stage of pernicious fever. The anæmia and cachexia, which followed the syphilitic infection, manifest and develop themselves more rapidly and extensively; and repeatedly did I find myself obliged to desist from applying the subcutaneous injection of a very diluted solution of corrosive sublimate with albumen, because this insignificant operation produced too severe a shock, a proof how seriously the nervous system of my patients was involved.

In women of the indigenous race, the symptoms are comparatively mild, and the disease with them runs generally an almost latent course. I once was requested to see a Mexican prostitute who had infected quite a number of young men, some of whom I had under my treatment. Instead of finding her a wreck, as some of her victims were, she had the appearance as though she enjoyed unimpaired health. It has repeatedly occurred to me that from Mexican prostitutes might have originated the severe cases of syphilis which gave so much trouble to Malgaigne when he accompanied the French army into Spain. Mexico at that time formed a part of the Spanish kingdom, and it is not unlikely that a great many prostitutes flocked to that country on account of the war. The Spaniards at one time pretended that syphilis was first brought into their country from Mexico. This is not in conformity with historical facts. The celebrated poem on syphilis, by Fracastor, was published in the year 1521, after a regular epidemic had swept over southern and western Europe, and in Virchow's work on the same subject there is a still older poem mentioned, written in 1496, by a Venetian by the name of Sumaripa. The conquest of Mexico took place during the year 1520–21, which proves that syphilis existed in Europe long before.

But of one thing there exists no doubt in my mind, that the Spaniards who were infected by the Mexican women, after they had taken possession of that country, had so much severer trials to endure than they were accustomed to see in Europe, that for this reason they considered it a new disease. In our days, although we have more ample means at hand to combat diseases, thanks to the progress of modern science, syphilis is and remains a most formidable and stubborn disease, if a white man becomes infected by a Mexican woman of Indian blood. I have seen but one case of a white woman infected by a Mexican of the Indian type, but this one case convinced me that the same holds good as to the female sex, although it is a well known fact that the disease is generally much easier endured by women than by men.

In Europe and in this country, if a man suffers from constitutional syphilis and fecundates an ovum within a healthy woman, it is most probable that abortus of the fecundated ovum will

take place. In other cases the ovum may develop to maturity and terminate either in the birth of a still-born child with an eruption of pemphygus over its body, or an offspring living and showing the outward symptoms of syphilis, while in a small minority they manifest themselves at a later date. In Mexico I have hardly ever seen a syphilitic child born, but I have seen cases in which the disease appeared several months later. This I could only observe with Mexicans of the mixed race. I have met, however, quite a number of white men belonging to the Germanic or Saxon race, and Mexicans of pure Caucasian lineage, who remained without offspring, whose wives never conceived at all, and consequently never bore children or miscarried them. All those men had suffered long and severely from syphilis contracted from Mexican prostitutes. None of these men bear any signs or symptoms of the disease which once existed; they are in every respect healthy subjects, their virile power is not by any means extinct, only their power of propagating is lost; none of them infected their wives. Several of these men are now married in second matrimony for several years after they had been bereft of their first wives, and the result has been the same—no offspring.

I call your attention to the fact that a total absence of virile power, for a limited time however, has frequently been observed after typhoid fever, although the patients had passed long before through their convalescence. In these cases it is probably a paresis of the spermatic plexus of nerves which causes the temporary suspension of the functions of the organs of reproduction, and therefore it is quite a different state of affairs. In syphilis there are other causes, which may combine to deprive the semen of the male of its power of fecundating. We find, for example, that after other exhausting diseases the hair of the scalp may fall, but it returns after a certain time to its former state; while after syphilis we observe very often that the loss of the hair is permanent, or, at least, it never is restored to its pristine state. This would point in the direction of either an atrophy, or degeneration of the papillæ of the hair. Moreover, we find, as a sequel, amyloid degeneration of the glandular organs. This degeneration extends always from the walls of the finest arterioles into the parenchyma. It does not destroy the functions of the glands, but alters their products. For example, the bile and urine of persons thus affected show a different chemical composition to some extent from the normal state, the former being at the same time lighter, the latter darker of color. The amyloid degeneration is in reality the remnant of an infiltration or exudation, which, instead of passing through the fatty degenerations and subsequent reabsorbtion, remains in *statu quo*, enveloping the cells, and by means of its pressure or lesser permeability impedes the process of exosmosis, and thereupon the perfectly physiological production of the glands. Thus, similarly to what we observed in the bile and urine, as mentioned before, the product of the sexual glands is probably altered in the case of sterility alluded to. The spermatic liquid is either deficient in its composition or the spermatozoa do not possess the vitality and energy of their vibratory motion, which is required to carry them to their point of destination. It appears to me most probable that a qualitative or quantitative deficiency of protagon, which is generally considered to be the substance possessing the catalytic force in the human semen, might be the cause of the sterility in question.

I was not enabled to make more extensive researches in this interesting matter, although I consider it worthy of some careful investigation. The partial amyloid degeneration of the parenchyma of the testicles suggested itself to me as the most plausible explanation.

Oleate of Copper in Tinea Capitis.

Among the parasitic skin diseases, few are more annoying to the patient, or whose treatment is often so unsatisfactory and perplexing to the physician, than the affection popularly known as scald head. So says Dr. Robert Boal in the *Peoria Med. Mo.* for May. Its appearance is so familiar and well marked that any description of it is unnecessary. Nor can it be mistaken for any other affection. It is called by various names, trycophytosis capitis, tinea circinatis, tinea capitis, and others, all these names having reference to the parasite which produces these changes on the skin. The great difficulty in curing many cases largely depends upon the depth and extent to which the parasite has propagated itself. If its ravages are confined to the surface of the skin, and do not reach the hair follicles, any of the ordinary parasiticides will generally arrest the disease; or juniper tea, sulphur, and other remedies of that class will suffice. But if the parasite has burrowed down into the hair follicles, stronger remedies will be required. The milder agents which have been named may cause a temporary improvement by destroying the parasites upon the surface, while those that are under it, and in the hair follicles, are not reached. The remedy which he has found to most effectually destroy these deeply hidden parasites is the oleate of copper. His attention was called to this preparation some two years ago, in a paragraph in one of the medical journals, and he determined to give it a trial upon the first opportunity.

Last year he was called to see a patient 17 years of age, well-formed, robust, and in apparent good health. He found the entire scalp covered with large, branny scabs, from beneath which a discharge had issued which became hardened by the contact of the air, the hairs were broken off, and looked like stubble. They had lost their glistening appearance, were dry, and apparently dead. The eruption not only covered the entire scalp, but extended down to the upper side of the face, and over the ears. It was one of the worst and most unpromising cases he had ever seen. Nearly all of the ordinary germicides had been tried without avail, under other hands. He determined to use the oleate of copper. An ointment of cosmoline containing 20 per cent. of the oleate was applied twice a day, having previously gently removed all the detached and partially detached branny scabs with a hair-brush. Under this treatment the case began to improve, and at the end of three weeks the scalp assumed a healthy appearance, the hair grew rapidly, and

the disease was cured. More than a year has elapsed since that time, and there is no return of the disease. The oleic acid, with which the copper is combined, seems to have the power to penetrate to the depth of the hair follicles, laden with the copper, a combination which effectually destroys the parasite.

No constitutional treatment was used or required. The ointment should be well but gently rubbed upon the parts, once or twice a day, as required. In most cases an ointment containing from 10 to 15 per cent. of the oleate of copper will be strong enough. In his opinion this is one of the most efficient remedies we possess in this troublesome and disagreeable affection. He shall use it in the future as in the past, with more confidence than any other remedy, and he does not hesitate to recommend a trial of it to others.

Vitiligo.

Before the Ohio State Medical Society Dr. R. Harvey Reed, of Mansfield, read a paper on this subject, saying:

"Prof. Duhring defines this cutaneous disease as an acquired disease, consisting of one or more sharply defined, rounded, or irregularly shaped, variously sized and distributed, smooth, whitish spots, whose borders usually show an increase in the normal amount of pigmentation. In an analysis of 11,000 cases by Dr. McCall Anderson, he only met with four cases of vitiligo. It is not confined to sex, but is probably more frequently found in early adult life. The pathologists tell us there is an increase of pigment over the body, but in the author's experience it seems to prefer the hands, face, neck, and head. Microscopically it is found that in the one instance there is a remarkable increase of coloring matter of the skin which gives rise to the peculiar mottled or spotted appearance of the skin. All authors agree in a favorable prognosis. It is usually easily distinguished from morphœa chloasma, tinea versicolor, and lentigo. The author gave in tabulated form the differential diagnosis of these diseases.

"In his experience the treatment has been very unsatisfactory. The use of internal remedies is only valuable when the system is out of order. In the belief which generally prevails, that vitiligo is a nervous affection, he has used the hypophosphites combined with strychnia internally, associated with friction and frequent bathing, together with stimulating lotions or ointments, such as the bichloride, or mercury and rose-water, or hydrarg. ammon., combined with ungnent aqua rosa, but none of these were followed with beneficial results. The only remedy giving any apparent benefit was electricity used twice a week, one pole applied to the nape of the neck, brushing the parts with the other. A report of five cases followed.

"If this disease is a nervous affection, it is certainly located somewhere in the great sympathetic system, and by some disturbance of that interferes with the blood in its distribution of the pigment to certain parts of the derma. In the cases reported, it seems to have started in all but one in the right side, and in that it could not be stated. Author thinks causes are located solely in the nervous system. There is a possibility that a primary cause may exist in the capillaries themselves, or in that part of the derma in which the pigment is deposited.

"Until there is more light thrown on this interesting disease, which it is hoped this paper will call out, and a definite knowledge obtained in regard to its exact pathology by practical demonstration, the author, for one, will continue to believe it to be a purely nervous disease, under protest."

On the Conditions which Precede Keloid, and on Some Rare Forms of that Disease.

Mr. Jonathan Hutchinson contributes an able paper on this subject to the *London Med. Times* (May 23), which concludes with the following propositions:

1. That with keloid, as with other skin diseases, we must not expect too close a conformity to the type form.

2. That for clinical convenience we may recognize several varieties of keloid, the prognosis as to spontaneous disappearance and proneness to return after excision differing much in each.

3. That the first and most typical form is that in which keloid begins in very small, perhaps forgotten scars, and slowly spreads far beyond their limits into sound skin. In most cases the extension and duration are indefinite; and the hardness, glossiness, abruptness of outline, etc., are always well marked. The proneness to recur very quickly after excision is very great in these.

4. That in the second group, in which keloid growth begins in the middle of large scars, such as those of burns, it is seldom so well characterized. It often does not extend beyond the scar, and often, especially in young persons, soon begins to soften again and to gradually disappear.

5. That in a third form the keloid growth is deeper, and never produces the glossy, superficial, elevated, and spurred patches which occur in the others. These cases are very slow, and show but little tendency to spontaneous disappearance. They do not develop in connection with large scars, but rather with inflammatory damage to the skin. They are less prone than the others to recur after excision.

6. That although definite scars almost invariably precede the formation of keloid, yet that there are allied conditions which result rather from inflammation after injury than from anything which is demonstrable as cicatrix.

7. That the cases of multiple keloid prove either that there is in some persons a remarkable tendency to the disease, or that primary patches have the power of infecting the blood and producing others.

8. That there is little or no clinical proof of tendency on the part of keloid to pass into cancer.

—M. Henry Milne-Edwards, the celebrated naturalist, is rather in a delicate state of health, and, owing to his great age (he being eighty-five), his condition causes some anxiety to his friends. M. Alphonse Milne-Edwards, son of the above gentleman, was lately elected member of the Academy of Medicine, and, like his father, is also a distinguished naturalist and member of the Academy of Sciences.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE ABSORPTION OF MERCURY.

There are but few subjects which have given rise to as much discussion as the absorption of metallic salts, especially, however, of mercurial preparations, by the intact skin. At the last meeting of the Balneological Society of Berlin, in March of this year (*Deutsche Med. Zeit.*, April 6, 1885). the subject came up for debate, and it was shown that science has made a great deal of progress in this respect during the last year. As the results of some investigations, which will be published in future, were mentioned at this meeting by their authors, we have made in the following an extract of the same, especially as they definitely settle some long-mooted questions concerning the power which the intact skin possesses of absorbing mercurial and other salts.

The President, Dr. Liebreich, well known by his introduction of hydrate of chloral into our therapeutics, reported that his investigations had convinced him that corrosive sublimate is absorbed by the healthy skin, if the mercurial salt be incorporated in a warm bath; and what is very peculiar, and has thus far not yet been known, is that but very little of the absorbed drug passes out by the kidneys, but most of it is found in the intestinal canal, whence it leaves with the fæces.

The fact had long been recognized that in poisoning by corrosive sublimate, the kidneys soon ceased their function, the uriniferous tubules being found clogged up with a whitish mass, which for a long time was believed to be the mercurial salt. Dr. Zuelzer has discovered that in such cases of poisoning the corrosive sublimate finds its way into the bones—the latter use a great amount of their lime salts—and it is these lime salts, which, being removed from the circulation by the kidneys, accumulate in the uriniferous tubules and obstruct their passage.

In Middeldorpf's clinic, in Breslau, the first trials were made to cure goitre by inducing absorption of iodine by electrolizing iodide of potassium directly over the goitre.

Dr. Liebreich has for some years been using at his lectures at the University of Berlin a small apparatus invented by the late Prof. Burns. To

show students absorption by electrolysis, he lays bare the masseters of a rabbit, and applying iodide of potassium on the one side, he obtains a deposit of free iodine on the other.

We may consider, therefore, the following facts as proven: Corrosive sublimate and some other metallic salts, if kept in solution and added to a warm bath in which the patient lies, is absorbed by the intact skin. Most of it leaves the body by the alimentary canal, and not by the kidneys. In cases of poisoning, either by a single too large dosis, or by medical administration too long continued, the mercurial salts are deposited in the bones—a fact for many yeays denied, and looked upon as a superstition left over from the Middle Ages—the bones becoming deficient mainly in lime salts, which are extracted from the blood by the kidneys, and there choke up the fine tubules, the white deposit in these cases not being fat, as once believed.

DEATH FROM A SNAKE-BITE.

Although many cases of deaths from snake-bite are yearly reported in the daily papers, they usually happen where original research is not abundant and medical aid sometimes not even near. This may be the reason why there are comparatively but few cases of death from snake-bite on record in which a careful post-mortem examination had revealed the morbid changes. The article recently published by Dr. A. Romiti (*Arch. Ital. de Biol.*, Tom. v., Fasc. 1, 1885,) is, therefore, of interest, as it concerns a case of the kind mentioned.

A workman, who had tried to catch a snake (*Vipera Redii*) in the woods, was bitten by it twice in the dorsal surface of his right hand. He at once fainted; his skin was covered with a cold, clammy perspiration; the impulse of the heart diminished in frequency, and could scarcely be felt; vomiting ensued; the tissues around the wound began to swell in a high degree, and although a ligature was applied, aqua ammonia dropped into the wound and administered internally, and thorough cauterization practiced with Paquelin's apparatus, deep coma soon set in, and four hours after the bite the patient died from asphyxia.

The case is remarkable in more than one point. First, cases of death from a bite of the viper are not frequent; amongst 200 bitten by the snake, and suffering from the consequences of the poisoning, but two died according to the statistics of Boullet. But the other interesting point is the one already mentioned—the exhaustive macro- and microscopical examination after death, and the result exactly coincides with the observations hitherto made upon animals experimented upon.

The pupils were dilated. The alveolar and muscular tissue surrounding the wound was infiltrated with a sanguinolent fluid. The blood contained in the veins of the arm was black. The lungs were hyperæmic. The heart had stopped in diastole. The pancreas was soft and of a yellowish color. Upon the lower surface of the liver many ecchymotic spots of various sizes were discovered. The same observation was made on the kidneys, which besides were soft, and their cortical substance hyperæmic. Microscopically a beginning interstitial nephritis could be demonstrated.

The intestinal mucous membrane was decidedly injected and full of ecchymoses. An examination of the blood showed the red corpuscles intact, but they were paler and formed no rouleaux. Amongst the red, white corpusles with granular contents were found. Thirty cubic ctm. of this blood, injected into the peritoneal cavity of a guinea pig produced no symptoms of poisoning whatever. Some of the blood, after having been kept for a period of five months in hermetically closed vessels, was still fluid and evinced not the least odor of decomposition.

Notes and Comments.

Various Applications of Muriate of Cocaine.

The field of usefulness of cocaine seems daily to enlarge. Dr. Barette, in *Le Concours Médicale*, May 23, 1885, reports a series of cases showing the various modes of application of this drug.

Grynfeld, of Montpellier, had to *introduce the catheter* in a man, aged twenty-seven years, whose

urethra was exceedingly sensitive, in fact, so irritable that the moment the instrument entered the channel the severest pains and a muscular spasm prevented its further introduction. G. then injected about one fluid drachm of a five per cent. cocaine solution into the urethra. Immediately after, the instrument could be introduced with ease and without giving rise to the least sensation. According to G., the cocaine in these cases causes not only perfect anæsthesia of the urethra, but it also completely prevents the febrile excitement due to increased sensitiveness of the parts, and, therefore, of reflex character.

A woman, aged sixty-nine years, presented in the bulbar region of the urethra a very hard and oval tumor. The application of the metallic bougie convinced G. of the presence of a *calculus*. After dilatation of the meatus, a four per cent. solution of muriate of cocaine was injected into the bladder; and later, the same kind of solution was directed against the parts where the calculus was situated. The latter was surrounded by soft parts. A few minutes passed by, when the soft parts could be divided and the calculus extracted without the patient's having experienced the least annoying sensation. Cure complete. The case indicates the employment of cocaine in lithotripsy.

Dr. Estery, in Bédarrieux, was consulted by a man æt. 70, who suffered from an *epithelioma* of the size of a cherry on the left jaw. E. injected 2 grains of cocaine, dissolved in water, under the skin, at the base of the tumor. Five minutes later, complete anæsthesia had set in within a radius of one inch from the tumor. The incision into the skin and the excision of the malignant growth were performed without giving rise in the patient to any pain whatever. But when the operator touched the areolar tissue below the tumor the pain was decidedly felt. This case seems to prove that the anæsthesia, when thus produced, does not extend very far.

Dr. Barrette, however, cautions against too forcible injections into the external meatus, and relates the case of a patient suffering from purulent discharge, accompanied by excessive pains, especially at night. Other remedies having been tried in vain, a four per cent. solution of muriate of cocaine was resorted to, and injected with great force into the ear. A minute later all pain had ceased, but within about ten minutes the most excruciating pains developed themselves, and an examination instituted the next morning revealed the disagreeable fact that a grave inflammation of a purulent character of the inner ear had set in, a morbid condition which had not previously existed. Barrette also mentions some other cases in literature where forcible injections of fluid into the external auditory meatus were followed by the gravest consequences. The tympanum in these cases often easily yields, and some of the pus is thus carried into the inner ear, where it at once gives rise to the same purulent inflammation that had existed more externally. As there anyhow does not seem to be any special benefit to be derived from them, it is better to discard such injections altogether.

Equinia Mitis.

Dr. Benjamin Strachan thus writes in the *Brit. Med. Jour.*:

Some weeks ago, I had under treatment a carter, aged about forty-five, whose ailment seemed to come under the above category. About six weeks before I saw him, he had been working an old horse affected with grease, and had occasion frequently to manipulate the diseased parts; and, for some time before taking to his bed, he had suffered from what he took to be rheumatic pains in various parts of his body. At last he was obliged to give up work, from the severity of the pain in the lumbar region and along the course of the right sciatic nerve; and, after two days in bed, an eruption appeared on the outer aspect of the right leg, extending from about six inches above the knee to within four inches of the ankle-joint, and partially invading the popliteal region. This consisted, at first, of large and small bullæ, speedily succeeded by a profuse eruption of pustules, arranged in small clusters upon a base, which speedily swelled, presenting the appearance of a large crop of small carbuncles, which discharged pus, and some of them cores, through perforations of the skin, where the pustules had been. These perforations had the appearance as if the skin had been riddled with pellets. Immediately before and during the earlier period of the eruption, the leg was much inflamed and swollen, and there was considerable pyrexia, with severe headache, nausea, and sleeplessness. The glands in the right groin were tender and swollen for some days, but did not cause much trouble. There were only one or two more inflamed pustules on other parts of the body, and I was inclined to regard it as a form of herpes zoster, aggravated by equinia poisoning. That it was infectious, was soon proved by his wife, who attended upon him, being attacked by it, though less severely. An angry pustule appeared upon the back of one of her little fingers,

attended with great pain, redness, and swelling, which began rapidly to extend over the hand, but was checked by a free incision over the pustule, followed by fomentations and poultices. This was succeeded by an erysipelatous blush round the left eye, with a small abscess over the inner canthus. The husband was confined to his bed for three weeks, but has now entirely recovered. The treatment in his case was iron and quinine, and chloral, with linseed and charcoal poultices, and carbolic and lead lotions. The wife, although feeling much out of sorts, was never laid up.

Conception without the Appearance of the Menstrual Flow.

As a matter of interest we note the following case which Dr. Arthur Oakes reports in the *Brit. Med. Jour.*, June 13:

Mrs. ——, aged about 30, married about six years, has been delivered at full time of three healthy children, and is now pregnant with a fourth. She menstruated quite regularly and naturally before marriage, and for a few periods after. Since then she has had no menstrual discharge whatsoever, nor, indeed, any appreciable discharge of any kind from the vagina, except the lochia, which were natural in quantity and duration. She had no connection with her husband for some weeks after the cessation of the lochia. Her first child was born about twelve months after marriage, and she suckled it until it was fifteen months old, until, as she says herself, she felt sick in the morning and knew she was pregnant again. The same thing has occurred with each child, menstruation never having been re-established since she was pregnant with the first. Having questioned and observed the woman very closely, I think it impossible to entertain any doubt of the correctness of her statement. A well authenticated case, such as I consider this to be, shows pretty clearly that there cannot be that intimate relation between ovulation and menstruation that some authors seem to think. Ovulation can undoubtedly occur without menstruation (as in this case), and we know the menstrual flow does occur without ovulation, as in cases where menstruation has occurred after amputation of both ovaries.

Poisoned by Tincture of Digitalis.

Le Concouer Médical, May 23, 1885, publishes an observation of Dr. Jeanton, resident physician in Hospital Saint Louis, concerning a case of poisoning by three fluid ounces of the tincture of digitalis. The whole quantity had been swallowed at once by the servant girl of an apothecary. Within a few minutes intense vomiting set in, and it is probable that a large portion of the poison was thus eliminated, and another part by emetics, which were administered at the hospital, whither the patient was at once carried. The symptoms which later developed themselves, may be placed in two groups, one attributable to the gastritis (intolerance of the organ, pains in the epigastric region), and the other produced by the disturbance of circulation, which would probably have been far more severe had assistance not come at once; irregularity and slowness of the pulse, but mainly nervous troubles, as violent delirium, necessitating the application of active measures, cutaneous hyperæsthesia and muscular hemiparesis, vertigo, amblyopia, and xanthopsia.

The eighth day the cure was complete, no sequela whatever apparently remaining. Besides the treatment mentioned, stimulants were mainly employed, as, for instance, hypodermic injections of ether, administration of carbonate of ammonia, inhalation of aqua ammoniæ, strychnia, and later, iron, external stimulating frictions, application of electricity, atropia, and a carefully-regulated diet as soon as the irritability of the stomach ceased.

Starvation and Suspended Animation.

Dr. Edward Berdoe reports the following case in the *Lancet*, June 23: He was called on, April 29, 1885, to see a man named Samuel B——, aged seventy-four. He found him lying on the floor insensible and dying. His wife sat near him, and on being questioned admitted that he had been lying in the same position for six days without food, drink, or any attention whatever. On raising him to place him on the bed, part of the flesh of his face adhered to the floor and was torn off. The exact form of the patient was marked on the floor by the exudation from the skin. He was in a most filthy state, and though unable to swallow even liquids, lived about fourteen hours after the first visit. By the coroner's order a post-mortem was made. The body was fearfully emaciated, and all the parts that had been in contact with the floor were gangrenous. The organs presented the usual appearances of death from starvation, but the medical interest of the case was found in the condition of the heart. This was enormously hypertrophied and dilated; all the vessels were atheromatous, and there was a large aneurism of the arch of the aorta. The cardiac condition seemed to satisfactorily clear up some of the difficulties of the case. From the evidence at the in-

quest it is probable that the wife's statement was correct, that he had fallen down "in a fainting fit" six days previous to the visit, and had not moved or spoken since. The heart presumably beat with just sufficient force to keep the respiratory organs going; this was, of course, favored by the recumbent position. The case is interesting from a medico-legal point of view, as showing how long a person may live in a state of syncope.

Hysteria in the Male.

M. Charcot has recently devoted some of his clinical lectures at the Salpêtrière to the study of six cases of hysteria observed in male patients. He classed, under hysteria, the affection known as railway-spine and railway-brain, a classification recognized as just by Putnam and Walton, of America, and Page, of England. M. Charcot quoted from their works. From 1875 to 1880, five doctoral theses have been written on hysteria in man. M. Klein, the author of one of these theses, collects 80 cases. M. Batault has collected 218, of which nine are M. Charcot's patients. M. Charcot told his pupils that hysteria in male subjects is not rare. It is an affection that is misunderstood and often overlooked. If it be occasionally recognized in weak young men of an effeminate type, who have suffered intense emotion, it is not admitted that a strong vigorous workman is susceptible to hysteria. Yet examples have been furnished by stokers after a railway accident. Dr. Charcot attributes the ignorance concerning this neurotic affection in man to a false appreciation of it in female patients. In male patients, hysteria lasts a long time, and the symptoms are durable; with women, the contrary is the case. This difference leads those who have not a thorough knowledge of this neurosis to overlook its appearance among male patients. Even women sometimes present hysterical phenomena that remain permanent, which are difficult to modify, and sometimes resist all medical treatment.

Gastrotomy.

The Berlin correspondent of the *Brit. Med. Jour.*, July 4, 1885, writes:

The following case of removal of a foreign body from the stomach was reported in a recent sitting of the Dresden District Medical Society by Dr. Credé: A man aged twenty-five, of delicate frame, came into his clinic after having swallowed, a fortnight previously, the whole set of the teeth of his upper jaw. He had pushed the teeth down his throat because they were choking him, as he could not bring them up again. As they did not pass naturally, and signs of inflammation of the stomach became visible, Dr. Credé performed the operation. A diagonal cut fifteen centimèters long was made below the ribs, the stomach was taken out, and opened by a cut seven centimètres long in the centre of its anterior aspect; the set of teeth was removed, and the rent in the stomach sewn up by three sutures, one above the other. The stomach was then replaced in its proper position. There was no inflammation, discharge, or pain of any kind. The second day after the operation the patient received liquid nourishment, and after a fortnight solid food. In three weeks he was dismissed, and was able to resume his work. This is the second case of a set of teeth that had been swallowed being removed by an operation, and the seventh in which gastrotomy was resorted to. The greater number of cases were successful. The first three cases were those in which a knife, a spoon, and a fork, respectively, had been swallowed.

Recovery from Rupture of the Uterus.

On April 27, 1884, Dr. Walter Buchanan (*Brit. Med. Jour.*, July 11, 1885,) was called to attend Mrs. K., with her second child. On his arrival she had one pain, and then a sudden cessation. On examination, he found the head of the child impacted in the pelvis (labor had only existed about two hours). He then gave a dose of liquor ergotæ, and attempted to deliver with forceps. Finding he was not successful, he sent for his friend, Mr. H. Tribe, who managed, with the utmost difficulty, to deliver her in about fifteen minutes. The placenta followed almost immediately, also an immense amount of hemorrhage. On examining the uterus, they found an extensive rupture of the fundus, through which the hand passed, and they could feel the intestines and spleen. They gave brandy and ether, and also at intervals injected subcutaneously a drachm of sulphuric ether. She seemed to be moribund. She was pulseless and blanched; the pupils were fixed and dilated. They persisted with ergot and ether, and remained during the night, expecting every moment that death would ensue. To their great surprise, she rallied; on the next day, still more so. She was fed on brandy and milk, and ergot was administered every three hours. On the third and fourth days, she had persistent diarrhœa, which was with difficulty overcome by compound chalk mixture. After this, she made a rapid recovery, being about in three weeks.

The Relation Between Gonorrhœa and Ophthalmia Neonatorum.

The *London Med. Times*, July 11, 1885, tells us that Drs. Leopold and Wessel, contribute to the *Archiv für Gynäkologie* (Band xxiv., Heft 1,) a paper which, if the facts contained in it are confirmed by other observers, is a very important one. That the ophthalmia of the new-born is due to inoculation of purulent discharge from the mother's vagina is commonly accepted. It is also commonly believed that it is next to impossible to be positive whether a purulent vaginal discharge is gonorrhœal or not. Leopold and Wessel have not been content to rest in this inexactness. In eighteen cases of pregnant women with purulent vaginal discharge they examined this secretion for the gonococcus of Neisser. In seventeen of them none were present; no precautions were taken to prevent the infants of these seventeen from getting ophthalmia, but none of them suffered from it. In one case Neisser's gonococci were found without doubt; the child from this woman on the fourth day had ophthalmia. These researches go to show that we have in the gonococcus of Neisser a certain test of gonorrhœa; and that gonorrhœa is the actual and true cause of ophthalmia neonatorum; two general propositions, which, if corroborated, are distinct strides in our knowledge.

Urari in Tetanus.

Before the Academy of Medicine in Ireland, Mr. McArdle read the notes of a case of acute traumatic tetanus, in which two-third grain doses of urari every fifth hour resulted in a cure, the more remarkable effects produced by the above-named doses being relaxation of the contracted muscles in from six to ten minutes after administration, very rapid and tumultuous action of the heart, cyanosis, labored breathing, and dilatation of the pupils. Once the patient was sufficiently under the influence of urari, the evacuations from the bowels were regular. Mr. McArdle suggested the combination of urari with pilocarpine, in the hope that the cardiac and respiratory trouble produced by the former might be prevented by the latter. He also showed that urari, to be of service, must be used in large doses, and that the drug is cumulative.

Olive Oil as a Menstruum to Dissolve Cocaine for Use in the Eye.

Dr. Jos. A. Andrews thus writes to the *Med. Record*, July 18:

"In addition to the occasional benefit derived from the use of oil dropped into the eye in recent abrasions from burns, and in other painful affections of the cornea in which atropia is indicated and cocaine may likewise be serviceable, the plan of dissolving the cocaine in oil seems to insure a longer contact of the remedy, and a smaller quantity is required to affect anæsthesia. Neither the salt of cocaine or that of atropine is soluble in olive-oil, but the alkaloid dissolves readily in this menstruum without the addition of alcohol, it being only necessary to expose the solution for a few minutes to a gentle heat in a water-bath. Castor-oil is not a desirable menstruum on account of its irritating qualities; and the oleate of cocaine, for the same reason, is still more objectionable as an application to the eye."

Correspondence.

The Cause of Phlebitis.

Eds. Med. and Surg. Reporter:—

As one of the constant readers of your excellent journal, it becomes me to express my satisfaction with the variety and amount of information contained in its numerous articles; and not least satisfactory among them are the reports of clinical lectures by the various professors who enlighten their hearers, and through the reports, your readers. Their opportunities for seeing a large number of cases are so much superior to ours that, even if we sometimes differ in opinion from them, it is with the mental reservation of our opinions in deference to their experience and standing. And so they set us to thinking, perhaps to experimenting, and sometimes to changing.

But sometimes we get staggered. We have been taught, and believe, certain things, and we are loth to have our supposed knowledge shown to be ignorance. We have no opinion to express with reference to hospital therapeutics, however freely we might discuss the treatment of disease in the country and smaller cities; but when the subject is physiological or etiological, where there is a common basis for opinion, we cannot accept the dictum of any one unless it favorably appeals to our reason.

In a late number of the Medical and Surgical Reporter a report is given of a clinical lecture on phlebitis, in which the etiology is discussed and a statement made which does not strike us favorably. Here is the statement:

"Suppose that the inflammation of the vein is *not a local* trouble, * * * how may it be caused? The other cause is the transference of a septic embolus to a pocket of the vein. Suppose you have a dysentery, there is ulceration of the bowel, and phlebitis occurs, what is its probable cause? In an inflamed vein in the neighborhood of the ulcer a thrombus has formed, which in turn has given off an embolus, which in a large majority of cases is septic. *This passes into a vein of the extremity, creates irritation, and produces septic phlebitis.*"

Now we are taught that the direction of the

venous blood-current is always toward the heart (with the single exception of the pulmonary circulation); that, arrived at the heart, all the blood passes through the pulmonary capillaries, thence, by way of the heart and arteries, through the peripheral capillaries into the veins, so that there can be no *direct* passage of an embolus from a vein of the abdomen to an extremity—it must pass through two sets of capillaries to find such a lodgment. Is not such an embolus rather refined? The capillaries are very small. Eliminate its alleged septic character, and it is hard to imagine its irritating power. But eliminate the embolus and leave the septic poison, and we can hardly argue that it may not be a predisposing cause, which may be determined locally by some trivial blow or pressure which escapes notice entirely. Possibly the pressure of one leg thrown over the other for a certain length of time, producing retardation of flow, might suffice; and as the right is probably oftener thrown across the left, it may account for the greater frequency on the left side.

But we did not start out to theorize. The professor's explanation did not satisfy us. If we are wrong, let our doubts be explained away and the truth made plain. O. A. Dean, M. D.

Beloit, Wis., July 25, 1885.

Fatal Hemorrhage from the Umbilical Cord.

Eds. Med. and Surg. Reporter:—

On the very oppressive evening of the 21st of July I was called to attend young Mrs. H——, primipara. The head presented in the first anterior position, and my patient, although somewhat excited by the experience of her first parturition, was safely and naturally delivered, after suffering about eight hours.

The child, owing to the rather slow progress of the second stage, and because it may have been a couple of weeks premature, seemed somewhat feeble when born; but, after a little attention, respiration was well established, and I proceeded to tie the cord.

As has always been my custom, I had requested beforehand that for this purpose there should be secured a piece of white braid about one-sixteenth of an inch in width.

I examined the funis, which seemed natural in appearance, without hernial tendency, and, after stripping it slightly in the direction of the placenta, tied it about an inch and a half away from the navel, drawing the ligature as tightly as possible. After placing a second ligature, I cut the cord, and then, examining for some seconds the stump, and wiping its cut surface off clean with my thumb, seeing there was no disposition to even the slightest oozing, I handed the child to a woman in attendance, and she, wrapping it in a large clean sheet, laid it down until ready for dressing.

Believing the child was all right, having carefully attended to the mother, I prepared a navel-rag, and telling the nurse how to put it on, I went down-stairs with the intention of departing soon. A few minutes later, I was hastily summoned to see the child.

The nurse, on taking it up, had discovered in the sheet large quantities of blood, say perhaps three or four ounces, and the child was found exsanguine and gasping. In spite of position and stimulation, it died about twenty minutes subsequently, and what had promised to be a most successful *accouchement*, was changed at once to a very disappointing one.

The cord, as soon as the hemorrhage was observed, was examined. The ligature was intact. The button-like stump was stained all over, as if from general oozing, but no blood was then escaping, syncope having occurred. I placed, however, then a second ligature, although entirely unnecessary, as there was no subsequent bleeding.

Now, I have been thus, perhaps, unnecessarily concise in describing my case, with the view of inviting criticism of my treatment. I must say, however, that I did in this case just as I have done in hundreds before it, and shall possibly do hereafter, except that I shall in future watch the navel very carefully. Twice before, in my practice of twenty-three years, I have been called to apply a second ligature to stop bleeding, soon after the child was separated from the placenta, and neither child died. In my fatal case, the ligature was very firmly drawn, and seemed, as I have said, sufficient. In conclusion, I may say I know of no theory to account for the fatal occrrrence except that the child may have been born with a hemorrhagic diathesis, which betrayed its existence by secondary bleeding, in spite of a firmly-applied ligature. J. Gilbert Young, M. D.

How to Take a Pill.

Eds. Med. and Surg. Reporter:—

I have just read in your issue of July 25, "How to Take a Pill," by Dr. Asthalter.

Now if the pills are sugar-coated, his method does very well; but if they are not, the patient will generally get the bad taste of the pill, and this is really the most serious objection to pills. You know that in the vast majority of cases the pills *are not* coated. When a physician orders medicine in pills, the apothecary does not sugar-coat them.

I will describe to you a method that I have been using, which I discovered last year, which carries the pill down without the patient feeling its presence in the mouth or throat, and *never permits the pill to be tasted*, when it is not coated.

Take a swallow of water, and hold the head back, so that the water will be in the back of the mouth. Do not swallow the water until the pill has been dropped on its surface. Take the pill between finger and thumb (still holding head back) and carry it well back, without touching the inside of the mouth with it; then drop in on the water and swallow. The head will come forward, and the water opening and wetting the œsophagus takes the pill instantly to stomach. It does not "stop half-way down," and is not tasted. *Try it.* D. Benjamin, M. D.

Action of Calomel on Conjunctiva.

Eds. Med. and Surg. Reporter:—

In the Reporter of July 11, Dr. C. S. Turnbull accounts for the caustic action of calomel on the conjunctiva by the "well-known fact that

most samples of calomel contain free corrosive sublimate." But the same result follows the local use of absolutely pure calomel, and the internal use of iodine or the iodides at the same time. Under these circumstances I have seen severe ulceration result from the application of calomel to a patch of herpes præputialis.

San Diego, Cal.

NEWS AND MISCELLANY.

An Argument in Favor of the Restriction of Chinese Emigration.

When we, of the East, hear of the violent opposition to the ingress of the Chinese from our brethren of the Pacific slope, we generally accredit this opposition to mercenary motives; but when we read the following lengthy abstract from the *Daily Examiner* of San Francisco (July 21), we are not only horrified, but we are tempted to utter a most fervent prayer that these filthy scoundrels may not be allowed to increase among us. We quote as follows:

"The special committee appointed in February last to investigate the condition of Chinatown presented a lengthy report, from which the following extracts are taken:

"ASPECT OF CHINATOWN.

"When your committee commenced their investigations, they were impressed with the fact that the general aspect of the streets and habitations was filthy in the extreme, and so long as they remained in that condition, so long would they stand as a constant menace to the welfare of society, as a slumbering pest, likely at any time to generate and spread disease, should the city be visited by an epidemic in any virulent form. Your committee are still of the opinion that it constitutes a continued source of danger of this character, and probably always will, so long as it is inhabited by people of the Mongolian race. They are glad to be able to say, however, that the presence and operation of the surveyors since employed by them have had a most salutary effect —whether lasting or not—in inducing 'a general cleaning up' where filth was the rule before, until a better general aspect is now presented than was the case at the time when this investigation began. Knowing the peculiar habits of this people, it is not likely that this better condition of things will continue long, now that the operations of the surveyors employed by your committee have been concluded, or that anything better will follow than a relapse back into their more dense condition of nastiness, in which they apparently delight to exist. Nevertheless, something has been gained in the demonstration of the fact that by constant watching and close supervision the residents of Chinatown can be made to adopt somewhat better habits, and become less obnoxious—on this score, at least—as well as a lesser source of danger to the public health; and, therefore, it is perhaps well to inquire now whether it will not be wise to inaugurate new rules and a new policy, under which they must be brought, if they are to continue to remain among us. In speaking thus of the improvement that has taken place in the general appearance of Chinatown since your committee commenced its investigations, we would not be understood as saying that the condition of the locality is in any sense what it should be in point of cleanliness. Our effort is to point out the fact that, as compared with what it was four months ago, it presents an improved aspect. The difference is one of degree, however, and even in its bettered aspect, in its byways, its slums, and its purlieus, its habitations, some of its places of business and places of amusements, it is to-day the filthiest spot inhabited by men, women, and children on the American continent. All great cities have their slums and localities where filth, disease, crime, and misery abound; but in the very best aspect which Chinatown can be made to present, it must stand apart, conspicuous and beyond them all in the extreme degree of all these horrible attributes, the rankest outgrowth of human degradation that can be found upon this continent. Here it may be truly said that human beings exist under conditions (as regards their mode of life and the air they breathe) scarcely one degree above those under which the rats of our water front and other vermin live, breathe, and have their being. And this order of things seems inseparable from the very nature of the race, and probably must be accepted and borne with—must be endured, if it cannot be cured—restricted and looked after, so far as possible, with unceasing vigilance, so that whatever of benefit, 'of degree,' even, that may be derived from such modification of the evil of their presence among us, may at least be attained, not daring to hope that there can be any radical remedy for the great, overshadowing evil which Chinese immigration has inflicted upon this people.

"CHINESE POPULATION.

"No known method of census taking has ever yet sufficed to furnish an approximate idea even of the numbers of our Chinese population. It is believed that the system which has been adopted in the conduct of this investigation will result in establishing a more correct conclusion on this point, so far as the twelve blocks covered by it are concerned, than can be obtained through any other method. Every building in this district has been visited, examined, and measured; the number of rooms which each contains, and the number of bunks or sleeping accommodations given in the report furnished your committee by its surveyors, and certainly with approximate accuracy, the number of men, women, and children of Chinese origin *who sleep* in this district, is now known and is herewith given. On this basis, and through this system of computation, we are enabled to show what we believe is a fair return of the population of the district referred to. Your committee have found, both from their own and individual observations, and from the reports of their surveyors, that it is almost the universal custom among the Chinese to herd together as compactly as possible, both as regards living and sleeping rooms and sleeping accommodations. It is almost an invariable rule that every 'bunk' in Chinatown (beds being almost unknown in that locality) is occupied by two persons. Not only is this true, but in very many instances these bunks are again occupied by 'relays' in the

daytime, so that there is no hour, night or day, when there are not thousands of Chinamen sleeping under the effects of opium, or otherwise, in the bunks which we have found there. Besides these bunks, rolls of bedding for use in sleeping on floors and various other sleeping accommodations are found. All these bunks, rolls, etc., have been carefully noted and enumerated in their reports furnished to us by the surveyors, and from them we reach the following results of an estimated enumeration of the population of Chinatown. For convenient reference, the numbers of the blocks named from time to time in this report are those by which the same blocks are distinguished in the books of the assessor. The boundaries of the blocks so numbered are given as follows:

	Bunks.
Broadway, Pacific, Kearny, and Dupont	183
Pacific, Jackson, Kearny, and Dupont	796
Jackson, Washington, Kearny, and Dupont	1446
Washington, Clay, Kearny, and Dupont	976
Clay, Sacramento, Kearny, and Dupont	1388
Sacramento, California, Kearny, and Dupont	741
Broadway, Pacific, Dupont, and Stockton	477
Pacific, Jackson, Dupont, and Stockton	1969
Jackson, Washington, Dupont, and Stockton	2828
Washington, Clay, Dupont, and Stockton	2325
Clay, Sacramento, Dupont, and Stockton	1287
Sacramento, California, Dupont, and Stockton	764
Total number of bunks	15180

"Not only have your committee found that the rule is for two persons to each 'bunk,' and relays of sleepers through the day in many, if not most instances, but women and children seem also to be stowed away in every available nook and corner, without reference to any special accommodation being provided for them. Taking, therefore, the total number of 'bunks,' and multiplying that total by two, must be at least a safe minimum estimate of the population in those twelve blocks, with every probability favoring the conclusion that an addition of perhaps 20 per cent. would not more than cover the real number of Chinese inhabiting the locality. On this basis, allowing two persons to a 'bunk,' and adding no percentage for excess from any of the foregoing reasons, we have a population in Chinatown of 30,360. And this, your committee believe, is the lowest possible estimate that can fairly be made.

"CHINESE WOMEN AND CHILDREN.

"It is a less difficult problem to ascertain the number of Chinese women and children in Chinatown, than it is to give with accuracy the male population: First, because they are at present comparatively few in numbers; and, second, because they can nearly always be found in the localities which they inhabit. This investigation has shown, however, that whatever may be the domestic family relations of the Chinese empire, here the relations of the sexes are chiefly so ordered as to provide for the gratification of the animal proclivities alone, with whatever result may chance to follow in the outcome of procreation. There are apparently in Chinatown but few families living as such, with legitimate children. In most instances the wives are kept in a state of seclusion, carefully guarded and watched, as though 'eternal vigilance' on the part of their husbands 'is the price of their virtue.' Wherever there are families belonging to the better class of the Chinese, the women are guarded and secluded in the most careful manner. Wherever the sex has been found in the pursuance of this investigation under other conditions, with some few exceptions, the rule seems to be that they are here in a state of concubinage, merely to minister to the animal passions of the other sex, with such perpetuation of the race as may be a resultant consequence, or else to follow the admitted calling of the prostitute, generally of the lowest possible grade, with all the wretchedness of life and consequence which the name implies. That this is not mere idle assertion, the following statement of the number of women and children found in Chinatown in the course of this investigation, and which includes probably nearly every one living in that locality, will, we trust, sufficiently demonstrate:

Women	57	Living as families.
Children	59	
Women	761	Herded together with apparent indiscriminate parental relations, and no family classification, so far as ascertained.
Children	576	
Prostitutes	567	Professional prostitutes and children living together.
Children	87	

"CHINESE PROSTITUTION.

"This examination has led to the foregoing result in regard to the relation of the sexes. No well-defined family relations have been discovered other than as shown, while the next classification seems to be a middle stratum between family life and prostitution, partaking in some measure of each, if such a condition of things can be possible. The most revolting feature of all, however, is found in the fact that there are so large a number of children growing up as the associates, and, perhaps, the proteges of the professional prostitutes. In one house alone, on Sullivan alley, your committee found the inmates to be nineteen prostitutes and sixteen children. In the localities inhabited largely by prostitutes, women, and children, who apparently occupy this intermediate family relationship already alluded to, live in adjoining apartments and intermingle freely, leading to the conclusion that prostitution is a recognized and not immoral calling with the race, and that it is impossible to tell by a survey of their domestic customs where the family relationship leaves off and prostitution begins.

"WHITE PROSTITUTION.

"The investigations which have been carried on by your committee have developed another disgusting and surprising feature. It is in reference to white prostitution in that locality. The map accompanying this report shows in what sections and to what extent of area white prostitution exists in Chinatown. The number of degraded women who ply this vocation there is unknown. But the point that will impress itself more strongly upon the ordinary mind, is that these women obtain their patronage almost entirely from the Chinese themselves. Their habitations seem to have been taken up in the Chinese quarter solely for this purpose, and their mode of life seems to be modeled after that of the Mongolian, to a larger extent than after the manners and customs of the race to which they belong. Many, if not most of them, confirmed victims to the opium habit in one form or another, they present pictures of pallid wretchedness hard to parallel in

any community where total depravity rules supreme, and their sex sinks to the lowest point of human degradation. The Chinese drug and opium stores at night usually contain numbers of these wretched beings, seeking opium or medicaments for the physical diseases to which they are constantly subjected; and more wan, sad, hopeless, and wretched-looking faces the human eye seldom encounters in the streets or slums of the most populous cities of the world. This is a feature of prostitution in Chinatown with which it is difficult and perhaps impossible to deal. Your committee can only point out the conditions under which it exists as one of the numerous evils which attach to and grow out of the presence of the Chinese among us. It is one of the many counts in the indictment against the race, and upon which we hold them up for trial before the public opinion of our country, from which we bespeak a just and wise verdict. For the poor, wretched woman who enters this particular walk of life there need be no punishment other than her own miseries; no word of reproach, but all our pity. Let her 'who enters here leave hope behind.'

"WHITE WOMEN LIVING WITH CHINAMEN.

"Another surprising as well as disgusting feature developed in this investigation is the fact that there are numerous instances of white women living and cohabiting with Chinamen in the relation of wives or mistresses. In one instance where an example of this was found, there was one white woman living among a large number of Chinese women and children—the mistress of one or more of the 'little brown men'—who, when the place was visited by the surveyors employed by your committee, roundly berated them for thus invading the citadel of their domestic rights, and threatened various modes of punishment therefor. In one instance a Chinaman had assumed marital relations with a fair widow with several children by a Caucasian husband. At 900 and 902 Dupont street there is a white woman living with a Chinaman on the third floor; at 613 Jackson street, second floor; at 708 Commercial street, second story; at 708 Commercial street, third story; at 710 Commercial street, third story; at 718 Commercial street, second story. There are in each of the foregoing one white woman and one Chinaman living together. At 740 Commercial street, second story, and at 916½ Stockton street, there are two white women in each place living with Chinamen.

"CONCLUSIONS AND RECOMMENDATIONS.

"We have thus presented for your consideration and for the consideration of the public, the salient features of the mode of life, the effect upon home labor, habits, industries, vices, and contempt of local laws, of Chinese in Chinatown. It clearly appears that the present and prospective condition of things calls for a more energetic and better-defined line of policy than San Francisco has heretofore displayed, and the adoption and enforcement of such measures as will bring this people under the same control as that which is exercised over other citizens generally. We cannot shut our eyes to the fact that the Treaty and Restriction Act constitute no effectual barrier as yet against Chinese immigration. The tide may not be flowing in upon us so rapidly nor with the same volume as before, but 'the cry is still they come,' and the problem of Chinese immigration is not yet solved. Moreover, it is far better to face the fact that through British Columbia on the north and Mexico on the south the march of the Mongolian cannot be effectually stayed, except by such congressional legislation and such an expenditure of public moneys as shall render such a result physically impossible of accomplishment; and we must meet the issue as it is presented, and settle the question of how best to deal with the Chinaman when once he is among us, how best to protect ourselves from the baneful effects of his presence. The right of protecting ourselves, the right of holding the Chinese to the same responsibilities under the laws that other citizens are held, cannot be disputed. The fact that the race is one that cannot readily throw off its habits and customs, the fact that these habits and customs are so widely at variance with our own, makes the enforcement of our laws and compulsory obedience to our laws necessarily obnoxious and revolting to the Chinese; and the more rigidly this enforcement is insisted upon and carried out, the less endurable will existence be to them here, the less attractive will life be to them in California. Fewer will come, and fewer will remain. The very race proclivities which we thus abhor may be converted into a better safeguard against Chinese immigration than any law of Congress or any treaty, if these race proclivities, which are sure to run counter to our laws and our system of morals, are held sternly in check, at whatever cost to the state or to the city.

"COMPEL THE CHINAMEN,

"By municipal laws which are not only enacted but enforced, to live like our own race; prevent them from burrowing and crowding together like vermin; enforce cleanliness in mode of life; break up opium dens and gambling hells; restrict the number of inhabitants in any given block in the city; enforce upon the people, so far as may be possible by every legitimate method that can be devised, a cost of living that shall approach as nearly as possible that of the ordinary white laborer. Take away from the Chinaman by such methods as these the largest possible part of the profits of his earnings as they accrue now from his present mode of life, and thus exhaust every effort to bring him to the level of the at present fearfully-handicapped American laborer, and California, or San Francisco at least, will soon cease to be attractive as a place of abode, and a less profitable field of labor for the Chinaman than it is at present. Scatter them by such a policy as this to other States, and let other States take home to themselves the full measure of the extent of the curse of Chinese immigration, when they shall have felt the evil as we feel it here. Municipal laws that are made to be enforced, and that are enforced—that shall prohibit any greater number of people from living on the space covered by one block, for example, than now live on such space, taking, if you please, the most densely inhabited block outside of Chinatown for a standard as the limit of the rule; that shall embody the Cubic Air law as it at present stands; that shall compel the use of chimneys and proper cooking

facilities; that shall enforce cleanliness at the cost of the occupants; that shall restrict prostitution; that shall suppress and put out of existence barricaded gambling dens; that shall prevent, under the most stringent penalties, the violation of fire and sanitary laws of every description; that shall, as a sanitary measure, prevent the exhumation of the remains of deceased persons, except under a much heavier tax than at present imposed; that shall prevent overcrowding in their theatres—will correct as far as possible many of the abuses that grow out of the presence of this people, and can hardly fail to drive them from among us. Hold, if necessary, the property-owner responsible for the overcrowding or other unlawful use of his property, and make the penalty imposed for violation of such laws a lien upon the property itself, and San Francisco will soon cease to be a paradise or even an attractive place of habitation for the Mongolian.

"The report was placed on file, and the committee instructed to prepare an ordinance embodying the recommendations made in the report."

Notes from the History of Medicine and Medical Opinion.

Surgeon-General Chas. A. Gordon thus writes in the *Med. Press*, June 17:

During the *Sung* dynasty, namely A. D. 960 to A. D. 1280, the study of Medical Jurisprudence was greatly encouraged in China; voluminous works on Therapeutics were also published in the same period. In certain departments of jurisprudence the Chinese physicians then enjoyed, as at the present day they do, a very high reputation. Among other instances of superior sagacity in this respect to which, with or without good reason, they pretend, is the method by which they affect to discover whether a man found dead by strangulation had been his own executioner, or had been strangled by others; whether in the case of a body being found in the water, death preceded or followed immersion; and whether, in other cases, death has been the result of natural causes or of felonious violence (Hamilton's "History of Medicine," vol. i., p. 31).

In the First Age of mankind, according to the medical sages of ancient China, the ancients prepared medicines, but seldom used them, their health was so perfect; in the Middle Age virtue became degenerated, and strength decayed; then disease arose. At the present time, medicines are used for the cure of diseases when they lurk within the body, and caustics, sharp instruments, and moxas to drive away the distemper; and yet, all these inventions bring no great advantage. In these ancient views, it will be observed how closely the ideas held in China in regard to the origin of disease coincide with those entertained in regard to the same mystery by ancient Hindoo writers.

"There are six sorts of distempers"—so wrote *Chun-yn-y*. "The first, of the presumptuous or haughty; the second, of the covetous; the third, of the poor, who want the necessaries of life; the fourth, of those who have the *yang* and the *yin* irregular; the fifth, of those who from weakness and want of flesh are not able to take any remedies; the sixth, of those who give credit to quacks and imposters, and have no faith in regular physicians."

In the treatment of the sick—"Regard must be had to the age and constitution of the patient; to his constitution, whether of plethora or of inanition; also whether the distemper be new or inveterate. It is necessary likewise to examine the degrees of malignity in poisonous medicines. In short, we must not obstinately adhere to the letter of this rule on all occasions; but it must be moderated as different circumstances require." The sages, or masters of medicine, when they make use of remedies to restore the health of the upper region, take special care not to excite any disorder in the lower region; when in the lower region, not to disturb the upper; when in the middle, not to affect the upper or lower.

More than a score of centuries before Hippocrates wrote of critical days, and at a period even earlier than they were noticed by ancient Hindoo physicians, allusion occurs in writings of the time now referred to indicative of the fact that "crises in disease, and the natural tendency which the body has to cure itself by critical evacuations at certain periods," were eulogized in the time of Hoangti. And from that period down to the present the Chinese have continued to lay much emphasis on the periodicity of diseases, especially febrile diseases. Fever patients are thought to exhibit a marked change every seventh day, and, according to native opinion, such affections in their progress means "seven days light and seven days heavy." In the works of the ancient Chinese physicians, characteristic descriptions of particular forms of fever are given; thus intermittent fever was minutely and correctly described by them B. C. 2600. Two thousand years before our era also, the disease cholera was correctly described by them, and by the precise name by which at the present day it is known in China, namely, *hwo luan*.

A reference to the system of therapeutics and materia medica of the Chinese will suffice to indicate several important points in reference to their theory of disease, and also that on which their methods of treatment are based. For example, various diseases are by them assigned to "poisons" and "specific poisons" in the body; in regard to others the "humoral doctrine" holds sway as it did, and, indeed, still does to a certain extent among western nations. The doctrine of "blood poisoning," involving the administration of "blood purifiers," finds favor with the public, and profit to medicine vendors in China, as elsewhere.

Throughout their ancient writings various illustrations are to be met with of the doctrine of *similia similibus*, having from very distant times been carried into practice. From time immemorial the native Chinese system of treating diseases has been strictly *homœopathic*, things being presented which in their nature are believed to resemble things in man. Talismans and charms are used, even by "the profession," against epidemics; branches of the peach tree are suspended "by authority" over the doors of houses and cattle sheds to ward off evils of various kinds, very much as twigs of the mountain ash used to be, if, indeed, they are not still, in certain parts of Great Britain. Instances are related of men

having been *hypnotized*, the operators in these instances being women!

According to the physiology of the Chinese, man is a little universe, or microcosm, and to this microcosm is extended the operation of the *yang* and the *yin*, in other words the male and the female principles of nature. Here, then, we find reproduced, if, indeed, not the original of the theory to which allusion has already been made in reference to Egypt and to India, and certainly the prototype of a similar theory recently enunciated as an instance of the most advanced sciences of the present time, while in regard to the doctrine of nature, inasmuch as throughout the sphere of living organisms certain sexual characteristics present themselves, the idea represented in the two principles indicated by the yung and the yin was certainly as much in accordance with the phenomena of living things as that of Hippocrates long subsequently enunciated in regard to what by him was called Nature. A ready theory to explain not only the occurrence of diseases, but of temporary derangements in the functions of the body, is that of harmonious or inharmonious action of the two "principles" of Nature thus alluded to.

In China, and also in India, as already noticed, the administration of anæsthetics was well understood, and practiced from a very early date; they were applied locally or generally by the physicians according to requirements in particular cases, the root of aconite being used for the former, certain fungi for the latter purpose.

According to Chinese medical authors, more especially a work entitled *Taou-tchin-fa*, small-pox made its appearance in China about the year B. C., 1122; other writers, however, assign its first occurrence in that empire to the period of the Eastern Tsin dynasty, namely, A. D. 317 to A. D. 420. Inoculation with the virus of that disease had been known and practiced in China from the time of the Sung dynasty, namely, A. D. 960 to A. D. 1127, and there is reason to believe that it was so also for a long period previous to that date. But, according to Grozier (l c. p., 489), "the Chinese place less confidence in the practice of inoculation than the Europeans, and for this reason, because the former are convinced by numberless instances that it does *not* prevent a return of small-pox when it becomes epidemical," and further, "that the disorder, even when communicated naturally, does not in all cases secure the patient against the recurrence of the malady." (Hamilton's "History of Medicine," vol. i., p. 30.) In fact, as already noted to have been the case in India, so in China, the operation appears to have been performed more with the object of conciliating "the demon of small-pox," or the "deity" of that disease, than as a means of protection against the severe fatal forms of that malady. The operation is usually alluded to under the somewhat poetical expression "cultivating heaven's flowers," implying thus that its object was in reality the preservation, or at all events development, of the natural disease, the "poison" of which resides in the system till developed, as fire is concealed in the flint. If this interpretation be the true one of the references which occur to the operation in question, and a careful consideration of their purport leaves no doubt on the subject, the natural inference is, that in course of time the real object of inoculation passed away out of mind, and that prevention took the place of cultivation of the disease thus artificially introduced into the human system. The particulars here given bear an important relation to the general system of "inoculation" for various diseases now practiced. They indicate, moreover, the importance of research, in works referring to times past; and they point to similar results from the new system of "inoculation" as those which characterized the old.

The Chinese consider pulmonary consumption to be infectious; they account for the disease being thus conveyed on the hypothesis that at the moment of death of the phthisical patient, a "worm" is expelled which enters the body through the breath of those in attendance. Have we not then, in the hypothesis here indicated, an approach to, if not identical with that which assigns to the "bacillus tuberculi" the property of transmitting the disease alluded to?

Of surgical knowledge, the Chinese appear to be destitute. As a rule, their practitioners are timid operators; as to external operations, they are limited to scarifications, moxas, and plasters. From a translation by Dr. Lockhart of a Chinese treatise on midwifery, a few extracts will indicate the general purport of the whole. "The great energy of nature is called life. The passing into life is a spontaneous act of nature. In the present age we often hear of difficult labors; if they terminate favorably it is not because of human interference, and if otherwise, you do not mean to say that this is the fault of nature. Can it be that nature would slay a man at the very gate of life? Man should follow nature, and not interfere with her operations by useless meddling." And so on.

According to their belief, also, the principal part of the healing art consists in the *feeling* (*i. e.*, by means of the fingers) of the pulse. In determining the sickness by laying of the hand upon the pulse, Chinese physicians are peculiarly clever, and their knowledge in regard to this part of diagnosis is really surprising. They describe twenty-four different kinds of pulses, with their subdivisions. In their nosology, diseases are divided into more than a thousand different kinds, for the names of which it would be impossible to give in English the corresponding words to those represented in the Chinese characters. Their practice, however, is far in advance of their theory, and some of their treatises on dietetics and medical practice contain good advice, the result of experience.

As far as authority is concerned, their system of medicine has high claims on our consideration, being in this respect superior to that of the Greeks, and conjecturally so to that of the Hindoos. But at the present day it has so degenerated that it is now a strange combination of a few anatomical facts and some really useful observations buried under an absurd mixture of astrology and superstition.

Diseased Sheep in Chicago.

The Erie (Pa.) *Herald*, under date of July 29, 1885, says that hundreds of diseased sheep are overlooked daily at the stock-yards in Chicago, and slaughtered as mutton for the city. Says the ar-

ticle: "The health inspectors are in apparent ignorance of the fact that diseased sheep are almost daily sold at the stock-yards. Sales are made openly, despite the presence of inspectors, and no bar has thus far been interposed to stop the trade. The animals are shocking spectacles, and the idea that such stuff is sold daily as food for thousands is horrifying. A thousand diseased sheep are bought at the stock-yards daily by mercenary scalpers, and sold to the unsuspecting public as good mutton. A syndicate is interested in the traffic. A reporter paid a visit to the pens at the stock-yards recently for the purpose of investigating. No inspectors were about. Out of forty pens, twenty-eight contained diseased sheep, and on an average there were twenty diseased sheep in each pen. Scabs, foot-rot, and glanders or snuffles, were the ailments of the entire lot. The sheep, it was definitely ascertained, were slaughtered and were sent out to the local butcher-shops or to the Jackson street market."

The Grecian Bend.

Dr. E. W. Germer, of Erie, President of the Pennsylvania State Board of Health, was recently accosted on the street by a reporter of the Erie *Herald*, when the following conversation ensued:

"Doctor," said the reporter, "do you ever have people imagine they have the cholera?"

"Yes," replied the doctor, with his indescribable accent. "I know five or six cases where they were scared half to death. Some of them were men who had eaten cucumbers and drank beer. Beer and cucumbers will double them up every time. Fill a thin bottle with beer and put some cucumbers in, and the next morning the bottle will be burst. Another case was where a woman had drank a pitcher of ice-water. Blood-heat is ninety-eight degrees, and ice-water is thirty-five or forty degrees. No wonder the woman had the 'Grecian bend.'"

"Another cause of complaint," said the doctor as the reporter started to go, "is Paris green the farmers put on cabbages. They sprinkle Paris green on to kill the bugs, and some poor devil eats it, and he is sick."

Dietetic Errors as a Cause of Disease.

I have come to the conclusion that a proportion amounting at least to more than one-half of the disease which imbitters the middle and latter part of life among the middle and upper classes of the population is due to avoidable errors in diet. Further, while such disease renders so much of life, for many, disappointing, unhappy, and profitless, a term of painful endurance, for not a few it shortens life considerably. It would not be a difficult task—and its results if displayed here would be striking—to adduce in support of these views a numerical statement showing causes which prematurely terminate life among the classes referred to in this country, based upon the Registrar-General's reports, or by consulting the records of life assurance experience. I shall not avail myself of these materials in this place, although it would be right to do so in the columns of a medical journal. My object here is to call the attention of the public to certain facts about diet which are insufficiently known, and therefore inadequately appreciated. And I shall assume that ample warrant for the observations made here is within my reach, and can be made available if required.—Sir Henry Thompson, *in Popular Science Monthly for July.*

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the two weeks ended July 25, 1885.

Fessenden, C. S. D., surgeon. Leave of absence extended eight days on account of sickness, July 20, 1885.

Irwin, Fairfax, passed assistant surgeon. Granted leave of absence for ten days, July 14, 1885. To inspect unserviceable property at St. Louis, Mo., July 15, 1885.

Items.

—M. Coestu, of Paris, reports two hundred and ninety-eight cases of diphtheria treated by large doses of calmel, and only twelve deaths.

—Dr. Trileski has employed cocaine locally in vomiting and for the pains of labor. The effect in both cases was satisfactory. No effect was produced on the course of the labor.

—The Barotte prize, of 3,400 francs, awarded to the inventor of the most important and useful invention for agriculture, has been bestowed on M. Pasteur, for his discoveries in contagious diseases.

—The *Monthly Journal of Sciences* states, on the authority of a well-informed French contemporary, that the excrements of dogs are now collected in Paris and worked up into peptones and powdered extracts of meat.

—The Academy of Sciences, whose turn it is this year to award the Institute's biennial prize of 20,000 fr., has pronounced in favor of Dr. Brown-Séquard. M. de Brazza, the African explorer, was amongst the competitors.

—The Société Médicale des Hôpitaux has opened a subscription toward providing a bust of Dr. Noël Gueneau de Mussy, recently deceased, which is to be placed in the Hôtel Dieu, to which hospital he had been attached for many years.

—The average duration of life in cancer of the tongue is, without operation, ten and a half months; with operation, sixteen months. In some cases, after operation, the patients have lived for from two to five years, or even ten years. —*New York Medical Record.*

—Dr. Biefel and Dr. Poleck have recently discussed in the *Zeitschrift für Biologie*, the question of the relative fatal effects of charcoal fumes and of illuminating gas, it being asserted that in the former case .19 per cent. in the air of CO destroys human life in thirty-five minutes, while a limit of 1 per cent. is exceeded in the latter case before a similar result ensues. This is attributed to the presence of oxygen in the gas; but Dr. Wagner has disputed these conclusions on the ground that the experiments were not conducted in a satisfactory manner. He agrees, however, with the statement that a mixture of gas and air possessing fatal properties is necessarily in an explosive condition.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

DIAGNOSIS AND TREATMENT OF DENTRITIC CYSTIC TUMORS OF THE JAWS.

BY JOHN S. SMITH, D. D. S.,

of Lancaster, Pa.

Diagnosis.—Cystic tumors may be confounded with other affections which occasion swellings about the jaws, as enchrondromata, sarcomata, and myxomata, abscesses, and the collections of fluids in the antrum. Dental alveolar abscess may be distinguished by its acute course, and when in a chronic condition by the discharge of its contents through the fistula, either upon the gum, or within the oral cavity. The tumor formed by an abscess is never so sharply defined as is the case with cysts; with dropsy of the anterial cavity the distention of the facial wall of the jaw is more uniform than it is with cysts.

In some cases of cystic tumors, they present so formidable an appearance at first sight, that they may be taken for solid tumors; especially is this so when their walls are compact and well organized, nearly if not altogether obliterating the sense of fluctuation when pressure is made upon them.

Cases have come under the observation of the writer where it required the most delicate touch to detect any fluctuation when pressure was made upon the apex of the tumor.

In some cases the diagnosis cannot be determined accurately until after one or more teeth are removed that are involved with the tumor. After such operation, a probe carried through the alveolus will usually reveal the true condition of the lesion. One or more dead teeth are found involved—one, however, being the rule in most cases which have come to the notice of the writer, while two, and sometimes three, are implicated with the tumor. The dead tooth may be easily distinguished from the living ones by its opaque appearance. Such tooth may be carious, and it may not.

Primarily the dentritic cyst originates from what pathologists call a "cold abscess," that is, an abscess which has never opened; subsequently, having developed into a tumor. The interior of the cyst has a fibrous lining, and being compact in structure, is the seat of an inflammatory process. The cyst contains a puriform fluid; it may attain such magnitude as to invest several teeth and extend beyond the alveolar process. The tumor is usually oval in shape, with its apex on a line with the diseased tooth directly involved. The size of the tumor may be as large as a hulled walnut, or as small as a hazel-nut; crepitates under pressure, and feels like parchment. In cases of long standing, considerable resorption of the alveolar process takes place, and the teeth immediately connected will be loose; especially will this be the case if the alveolar borders are broken; these teeth should be removed. These tumors are found painless, as a rule. I have met with cases, however, where an acute inflammatory condition was present, with all the symptoms of acute periodontitis manifested. So that it could have been readily mistaken for the pointing of an alveolar abscess.

Pathology.—Cysts of the jaws may be either simple or compound; whether they be cysts of retention, exudation cysts, or extravasation cysts belonging to the jaws, is a matter not as yet fully

established. The exudation cyst is a secretory cyst; in a generic relation, however, it is just the opposite of the retention cyst. Serous sacs form the foundations of the exudation cysts. "The mode of development of cysts of the jaws," says Wedl, "has not yet been determined; it therefore becomes necessary, in order to throw more light on the subject, to pursue further anatomical investigations in that direction."

Rindfleisch says: "The accumulation of the fluid is not produced by the continuance of the normal secretion, but by an exudation surpassing the normal measure of the serum of the blood with salts, albumen, fibrinogenous substance, and extractives, in the most varying proportions. The exudation cysts have little to do with pathological new formation. Of extravasation cysts," he says, "a parenchymatous bleeding can very well be the point of departure for the formation of a cyst. The hemorrhagic depot can present itself primarily as a cyst, namely, when the blood is poured out between two surfaces in themselves smooth; for example, bone and periosteum, cartilage and perichondrium, and thereafter remains fluid. As a cyst may also be formed when upon the one hand the limitary parenchyma furnishes a connective tissue membrane, upon the other hand, the blood itself is resorbed through a series of metamorphoses up to a small remainder, and is replaced by a clear fluid."

The above-mentioned condition is liable to manifest itself within the body of the jaw, the bone and periosteum, after severe mechanical injuries to the bone, and the rupture of blood-vessels within the parenchyma. There can be little doubt that many of the so-called dentritic cysts of the jaws have their origin primarily from causes brought about by falls, strokes and mechanical violence, causing rupture of blood-vessels. It is quite true, history of cases fully confirms such facts.

Clinical observations lead us to believe, however, that only in cases where the abscess does not open, we find the pathological new formation taking place within the jaws. Pulpitis, and as has been observed, followed by pericementitis and periodontitis, is a prolific cause of the development of the dentritic cystic tumor.

Treatment.—The removal of all dead teeth involved. Other teeth whose pulps are living may be loose, and to a casual observer appear to be complicated, but a careful examination will reveal the fact that they should not be disturbed but retained in their places; only one tooth may be the offender, being a dead one which has caused the trouble. After the removal of the cause, let it be either one or more dead teeth or fangs of teeth, cyst walls may be punctured with a sharp instrument, and the contents of the sac released, this being done by carrying the instrument through the alveoli, and not through the bony parietes of the jaw. After the contents of the sac is let out, and the sharp spicula of bone trimmed, with engine burrs, tincture of iodine full strength may be forced into the cyst sac, by saturating tufts of cotton-wool and allowing them to remain, again repeating the treatment at intervals of a day. If necrosis of bone be present, it is good practice to alternate the iodine treatment with aromatic sulphuric acid. Cases generally yield to this treatment in from six weeks to three months. I have seen cases not yielding to treatment for nine months. There are other and shorter methods in the treatment which perhaps some would prefer—the cutting down through the body of the tumor, by making a crucial incision and scraping out the contents of the sac, afterwards allowing nature to do the rest—but I do not believe it is the best or the safest way. There is surely a much greater loss of structure, which is never restored as in the former method by granulation, after the secreting cells have been destroyed by medicinal applications of iodine and sulphuric acid treatment.

TWO OVARIOTOMIES SUCCESSFULLY PERFORMED ON THE SAME PATIENT.*

BY JOSEPH RANSOHOF, M. D., F. R. C. S.,

Of Cincinnati.

M. A., æt. 24, married, was admitted to the surgical clinic at Königsberg, Prussia, July 7, 1880. Until her marriage, five years ago, she was in perfect health. Soon after marriage irregular menstruations supervened. They would appear at intervals of eight to ten days, and continue for a like period. Three and a half years after marriage the menses disappeared for seven weeks, when, after appearing irregularly for a short time, they ceased entirely during the last four years. The patient has been conscious of an unpleasant sensation in her abdomen, but until lately has not suffered pain. Eighteen months ago she discovered an abdominal tumor, which has been gradually increasing in size. In last month pain has confined her to bed for a week at a time. She has never been pregnant. Patient is robust and well-nourished. Abdomen distended by a uniform swelling; greatest measurement 36½ inches. Palpation reveals firm, slightly un-

* Abstract of a paper read before the American Medical Association, April, 1885.

even tumor. Vaginal examination does not reveal the presence of a growth. The sound enters the cervix uteri readily, but can be pushed into the body only by depressing the handles of the instrument. An abdominal tumor was diagnosed. The operation was made July 28, 1880, under a spray of salicylic acid. The tumor sprang from the right ovary. A drainage-tube was inserted into the wound, which was closed by six quilled sutures, including the peritoneum, and twenty superficial sutures. Lister dressing.

Prof. Baumgarten described the tumor as follows: "Somewhat larger than an adult head, and is globular in shape. Its surface is smooth, and on one side the tube is attached. A section shows it to be an almost solid mass, from which, as from an opened honey-comb, there oozes, from innumerable orifices, a thick grayish-white secretion. Microscopic examination shows that the tumor consists of cysts, for the most part microscopic in size, the walls of which are covered with a single layer of epithelium, and are filled with mucoid masses."

Two months after leaving the hospital at Konigsberg she began to menstruate regularly. In 1881 she emigrated to America, and remained till the summer of 1884. In the spring of the previous year she discovered an abdominal swelling, which increased in size. Occasional severe abdominal pains, accompanied by vesical and rectal tenesmus, caused her to seek her bed.

Dr. Ransohof first saw the patient in October, 1884, in following condition: Rather robust woman, apparently in fair health. Abdomen presents evidences of first laparotomy, appearances of cicatricial tissue being present. Two inches above the pubes an ovoid body is felt. It measures an inch in width, and more in length, and is attached loosely to the cicatrix. The smooth surface of a tumor and the absence of adhesions is established. The tumor is central, and the abdomen presents a dome-like appearance; measuring, a little below the umbilicus, 42 inches. Palpation gives sensation of fluctuation. Vaginal examination shows the cervix high up and hard to reach. In the posterior cul-de-sac the vaginal wall is bulged downward by an elastic swelling, which is unconnected with the uterus, and by bi-manual examination is shown to be a part of the abdominal tumor.

In view of the history of the case and the signs presented, the diagnosis of multilocular ovarian cyst, with extensive pelvic adhesions, was made, and an operation advocated. This was done Nov. 19. with the assistance of Drs. Palmer, McKee, Wilder, and Krouse. An incision four inches in length was made in the median line. On dividing the peritoneum, the typical grayish-colored multilocular cyst was found. Adhesions were not found. A pailful of thick, ropy, chocolate-colored material escaped from the cyst on tapping it. No pedicle could be found. The floor of the sac was so firmly adherent to the rectum, the body of the uterus, and left side of the abdominal wall above the latter, that a separation of these adhesions was wholly out of the range of possibility. In view of the extensive pelvic attachments, it was decided to sew a portion of the cyst in the abdominal wound. A glass drainage-tube was inserted, and the wound covered with boracic acid. An iodoform gauze dressing was applied. Time of operation, 50 minutes.

On the third day temperature rose to 104°, but fell again. Patient gradually improved for four weeks, when an abscess formed at the left of the wound. This was twice evacuated. The patient left the hospital in ten weeks after the operation. At this date, three months after the operation, the wound is completely healed, and the patient able to perform household duties. Since the operation the catamenial flow has occurred four times, each time lasting from three to five days.

The three points the essayist thought the case opened for discussion were: The comparative frequency of cystic disease in both ovaries, the advisability of performing double ovariotomy when the disease in one gland is but little developed, and the method of treating the cyst by suture to the abdominal wall after more or less of it has been excised.

While, in the experience of Sir Spencer Wells, both ovaries must be removed in 8 per cent. of cases, in that of others it is necessary in 16 per cent. Of 32 cases of second ovariotomies, only 5, or 15.6 per cent. ended fatally. In single ovariotomy Wells and Kœberle show a mortality of 22 per cent. In double ovariotomy Wells has lost 34 per cent., while of Kœberle's 51 per cent. have died. The author thought unless patient be near climacteric period, or the disease in the second ovary be pronounced, double ovariotomy should not be performed. The author gave a tabulated statement of 32 cases where a second operation was performed.

The method of treating the cyst by sewing the small part, which could not be removed, into the abdominal wall, the author thought to be a feature of the greatest practical importance. For this procedure he ventured to suggest the name —ventro-cystorraphy.

CASES ILLUSTRATING THE USES OF THE GALVANO-CAUTERY.

BY WILLIAM F. WAUGH, M. D.,
Professor of Practice and Clinical Medicine, Medico-Chirurgical College of Philadelphia.

A lady consulted me for profuse leucorrhœa. Examination showed a small tumor springing from the inner anterior surface of the cervix. The slightest touch induced free hemorrhage, so that the view was obscured, and any operative procedure rendered difficult and uncertain. Having carefully introduced a Nelson's speculum, and waited for all hemorrhage to subside, I applied the cautery knife, at a dull-red heat, to the root of the tumor, and removed it with little difficulty. No hemorrhage occurred; the vessels being effectually sealed up by the heat.

Another lady had been long afflicted with nasal polypi. She had had them removed a number of times, but they had quickly reappeared. Ordinarily, we remove a few at each sitting, with forceps or wire snare: stopping when compelled to do so by the hemorrhage which obscures the view. In this case, after using the snare, I applied the cautery to the cut surface to check the bleeding, and was enabled to complete the operation at one sitting. I noticed then, that the patch of membrane from which the growths sprang, was studded with minute polypi, ready to develop at once, when the pressure of the larger tumors was removed. This surface was cauterized by passing the knife lightly over it; and there has been no return of the polypi.

A gentleman walked into my office some time ago, so woe-begone and emaciated that I did not recognize him until he mentioned his name, although he had been my patient for years. For two months he had been suffering with acute pain in his ear. During this period he had been under the care of an alleged specialist—a person who at intervals floods the city with advertising sheets, on which the anatomy of the ear is depicted by the aid of a few sorry wood-cuts. His treatment for the present case consisted in dusting a little iodoform upon the ear. Of its utility you may judge when I tell you that for weeks the man had been unable to masticate his food, or to sleep, and the pain was increasing daily. The external ear and the skin around it were swollen and reddened, as if with erysipelas. From the auditory meatus projected a raspberry-like mass, purplish in color, very sensitive, and bleeding when touched. I applied carbolic acid to its surface. (This was in pre-historic times, before cocaine was.) I then applied the cautery, using the utmost care to prevent its touching the lining of the meatus, and burnt off the mass until I had penetrated about half an inch into the ear.

Here I noticed some smeary substance on the scoop used to remove the debris, and on examination found it to consist of thickened pus. The tumor proved to be a mass of granulations springing from the side of the meatus. When this had been removed, and the pus cleared out, I came upon a substance resembling wet paper, which was removed with a good deal of difficulty, as it was too rotten to remove with forceps, and too tenacious for the scoop. This consisted of epithelial scales mixed with aspergillus filaments. Finally the meatus was cleared out, and the drum could be seen. By this time the erysipelatous flush had disappeared from the face and ear, the pain had ceased, and the patient was relieved. He afterwards informed me that on the way home from my office he stopped twice to partake of stewed oysters, so quickly did his appetite return when the cause of his trouble was removed. The pain produced by the cautery was so slight that he did not mention it during the operation. Three days subsequently he returned with the whole meatus filled with a growth of aspergillus. This was removed, the cavity dried and painted with carbolized oil. The patient was instructed to dry the ear out with salicylated absorbent cotton whenever he noticed any moisture about it. There has been no return of the disease since.

These cases will suffice to illustrate the value of the galvano-cautery to the general practitioner. I do not mean to imply that the galvanically-heated knife is different in its properties from any other cautery, but practically it is vastly more convenient. In operating upon hypertrophied tonsils in children, we must not heat the knife until it is touching the tonsil, and the child need not know that heat is used; while few children would remain quiet if you approached them with a cautery iron just drawn from the furnace.

When one has become familiar with this instrument, he finds many other uses for it. Hypertrophy of the nasal mucosa, hemorrhoids with relaxed sphincter ani, warts, condylomata, pinguculæ, sluggish ulcers, and numberless other affections may be advantageously treated by it, even by physicians who have not the training of the specialists.

The apparatus I use was constructed by Otto Flemming, of this city, and leaves little to be desired in the way of durability, cheapness, and efficiency. It is so simple in management that a

child could operate it, and it does not get out of order. In the one quality of portability it is excelled by the Paquelin thermo-cautery.

PECULIAR CASE OF POPLITEAL ANEURISM.

BY C. D. CHALFANT, A. M., M. D.,
Of Streator, Ill.

It may be that the case which I wish to present to the profession has frequent parallels in the more extended experience of those engaged in an exclusively surgical practice, but I have been unable to find such reported in any literature of the subject which it has been my pleasure to read. It is on account of its apparent anomalous nature and the failure on my part to find any similar cases recorded that it would seem to present some points of interest, if not of frequent occurrence. But all surgeons who have operated for popliteal aneurism are aware of the many complications which may have to be met in its management, and the large mortality which the history of the operation has shown to occur in the hands of the ablest representatives of our profession.

Michael H., aged nineteen years, presented himself, April 24, for an operation, with following history: When seven years old was cut with mowing scythe, showing old cicatrix three and a half inches below head of the fibula, and he had been lame from that time with a pulsating tumor extending from that point up to angle of knee. Had been operated on for what was supposed to be talipes equinus, without relief, symptoms evidently due to pressure from aneurismal tumor. Had gradually grown worse for past eleven years. One year ago digital and instrumental compression had been thoroughly and persistently tried; with an apparently favorable effect for a short time; but after using limb, pain and lameness increased, and as a final resort, he determined to submit to any operative procedure for relief. The limb was losing sensibility, and ecchymosed spots were making their appearance on the foot.

Realizing that the chances of success were not very great, and that the mortality ratio was large, he was apprised of the facts, and I proceeded with the operation, ably assisted by a number of medical gentlemen of this city. Having ligated several times for traumatic aneurism, but never in the popliteal space, it was my pleasure to gather all the facts possible on the subject, and I had fully decided to tie in Hunter's canal or in Scarpa's trangle, but the condition of the tumor and obstructed circulation in limb, and desire to save as much of leg as possible if it became necessary to amputate, caused me to cut down on the tumor, and tie both proximal and distal ends of the vessel. From the place of wound in the limb, the diagnosis seemed to point to the peroneal or posterior tibial as being wounded, and that tying one or both at point of injury might save the limb. After exposing the tumor and the firm bands of the soleus, and gastrocnemius muscles had been pressed aside, the sac gave way, and the coagula being turned out, the popliteal was tied. On investigation the posterior and anterior tibial and peroneal were found to be given off below, communicating with tumor. The fibula was nearly worn through, either by the constantly pulsating tumor for so many years, or the effect of the compression which had been so thoroughly tried the year previous, and its roughened edges had cut through the coats of the vessel until nothing seemed to hold it but the strong muscles external to it. With no reasonable hope of collateral circulation being sufficiently established, the leg was amputated by lateral flaps below the knee, but the subsidiary circulation from the muscular and cutaneous branches would not hold ligature, and Paquelin's cautery being of no avail, a secondary operation above the knee was made with about the same results, as every muscular fibre and arteriole seemed to bleed, the collateral circulation having been established by the development from childhood. At least twenty ligatures were applied, and as rapidly thrown off, actual cautery, warm and cold water, ice, astringents, all with indifferent success; but finally after three hours under the anæsthetic the hemorrhage ceased, and patient seemed to recover from the shock, and was comparatively comfortable until two hours later, when the circulation began to increase in volume and force. And although the stump was carefully watched for secondary hemorrhage, and tourniquet and Esmarch in place for emergencies, nevertheless the femoral broke, throwing off ligature and distal end of vessel with it, but was secured again at once, and tied; but patient gradually sank, and died from exhaustion three hours later.

Remarks.—The questions which this case brings me to consider are: Could anything have been done differently with better results? Had I tied in Hunter's canal or Scarpa's triangle, would results have been more satisfactory? So far as operation itself is concerned, every surgeon can appreciate with how much more ease this can be done than ligating in popliteal space. But the approaching gangrene of foot, and lost sensibility

of part from size of tumor, and obstructed return of venous circulation, seemed to direct the operation at the point selected; and yet were a similar case to present itself again, I should be in doubt whether to do the same operation or tie above the aneurism.

RECENT MEDICO-LEGAL MATTERS.

BY HENRY A. RILEY, ESQ.,
Of New York City.

A branch of law of great interest to physicians and surgeons, is that arising from the employment of the profession by servants of corporations in cases of accident, without the knowledge or authority of the higher officers. It cannot be said that there is any invariable rule on the subject, either fixing the liability for compensation, or relieving the corporation from it. Some of the States hold that the act of the employee binds the corporation in cases of emergency, and some deny that such is the rule.

The Supreme Court of Indiana has just decided a case in point by holding the corporation liable, and a statement of the facts upon which the judgment was rendered will be of interest:

Frankfort is a way station on the line of the Terre Haute and Logansport railroad, distant many miles from the principal offices of the company, and from the residences of the chief officers. At this station, at one o'clock in the morning of July 2, 1881, Thomas Coon, a brakeman in the service of the company, had his foot crushed between the wheel of a car of the train on which he was employed as a brakeman, and a rail of the track. The injury was such as demanded immediate surgical attention. The conductor of the train requested Dr. McMurray, a surgeon residing at Frankfort, to render the injured man professional aid, and informed the surgeon that the company would pay him for his services. At the time the accident happened, and at the time the surgeon was employed, there was no officer superior to the conductor at the town of Frankfort. There was at the station a resident agent, who had full knowledge of the injury to Coon and of Dr. McMurray's employment.

This agent was in telegraphic communication with the principal officers of the company, but did not communicate with them. Upon these circumstances, the court which tried the case held the railroad company liable, and a verdict of $100 was rendered in his favor. The railroad company appealed from this decision, and the Supreme Court of Indiana has just decided that the judgment was right and must be affirmed. The court considers at length the claim of the company that a conductor has no authority conferred upon him to employ surgeons and make the company pay for their services, when rendered without the knowledge of the officers, and that such action was totally outside the scope of his ordinary work as a conductor. After careful examination, it decides that in the special instance the claim does not apply. The rule that an agent can bind his principal only in cases within the ordinary scope of his employment is held to be a sound rule of law in most cases, but that an extreme emergency will give the conductor, who was the highest representative of the company at the place of the accident, the same powers to act that are ordinarily only enjoyed by the superior officials. Upon this point the judges say: "Can a man be permitted to die while waiting for the company to determine when and how it shall do what humanity and strict justice require? Must there not be some representative of the company present in cases of dire necessity to act for it? The position of counsel will meet ordinary cases, but it falls short of meeting cases where there is no time for deliberation, and where humanity and justice demand instant action. From whatever point of view we look at the subject, we shall find that the highest principles of justice demand that a subordinate agent may, in the company's behalf, call surgical aid when the emergencies of the occasion demand it, and when he is the sole agent of the company in whose power it is to summon assistance to the injured and suffering servant. Humanity and justice are for the most part inseparable, for all law is for the ultimate benefit of man."

HOSPITAL REPORTS.

LECTURES ON INSANITY.

Delivered at the University of Pennsylvania,

BY CHARLES K. MILLS, M. D.,
Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.
Reported by WILLIAM H. MORRISON, M. D.

LECTURE IV.

Melancholia—Definition—Varieties—Cases—Diagnosis from Mania—Diagnosis from Hypochondriacal Monomania—Prognosis—Treatment.

GENTLEMEN: Melancholia is the opposite of mania. It is a form of mental disease which has as its basis depression of the emotional nature. De-

pression may not be emotional, but rather logical, intellectual, or conceptional, and these very words indicate the differential diagnosis between two forms of insanity. Just as in mania, you may have with exaltation of the emotions other mental and nervous conditions, so in melancholia, depression of other functions as well as of the emotions may be present, but the depressed emotional state is the groundwork of the affection. Melancholia may exist in many degrees, just as is the case in mania. The simplest type is the one from which all present have probably suffered, and is termed a "spell of the blues," or "depression of spirits." Carry this to an extreme, and you have the idea expressed by the term simple melancholia.

Depression and dejection become profound. All the functions of the body become more or less stagnant. The speech, the countenance, the movements, the gait, and the general carriage of the patient, all express torpor and sadness. He breathes the air of despair.

> "Black melancholy sits, and round her throws
> A death-like silence, and a dread repose."

Melancholia has been sub-divided very differently by writers on psychiatry. One of the most recent subdivisions is that of Clouston, which is as follows: (1) Simple melancholia; (2) Hypochondriacal melancholia; (3) Delusional melancholia; (4) Excited (motor) melancholia; (5) Resistive (obstinate) melancholia; (6) Epileptiform (convulsive) melancholia; (7) Organic (coarse brain disease) melancholia; (8) Suicidal and homicidal melancholia.

After much consideration, I have concluded that it is better to subdivide into two chief forms, namely:

1. Melancholia without delusions, or simple melancholia.

2. Melancholia with delusions, or delusional melancholia.

It is possible to include all the forms of Clouston and others under one or the other of these heads.

Melancholia attonita, or stuporous melancholia, is a term sometimes applied to a condition in which the emotional system is absolutely overwhelmed; in which, indeed, to all appearances, not only the emotional, but largely the whole mental nature is overwhelmed, but at the bottom of the trouble is a terrible delusional condition. I prefer to consider this disorder under the head of *stuporous insanity*.

Melancholia, with delusions, takes many forms. In the first place, there is a distinct subdivision which can be properly termed hypochondriacal melancholia. Certain cases, often seen, cannot be well placed under any other head, and you have to speak of them as special forms of melancholia. In this condition of hypochondriasis or hypochondriacal melancholia, the patient's thoughts are centered on himself. He dwells on the condition of his organs and the diseases from which he thinks he is suffering. In one type of this hypochondriacal melancholia, he may have a distinct form of disease for almost every day—to-day, it is disease of the brain; to-morrow, of the liver; the next day, of the heart, and so on. You may sometimes, at a single interview, as I have done time and time again in my investigations, lead such a patient to tell you of ten or fifteen diseases with which he believes himself to be suffering. He gives the symptoms of the various conditions as far as he can, but as a rule, he can give no logical reason for holding the views which he entertains about himself. In another type the patient holds with great firmness to his belief of disease of some one organ or part.

A common form of hypochondriacal melancholia is that in which the individual's morbid thoughts become centered on his sexual organs. Thoughts of impotence, of nervous break-down, of failing mind, etc., are demons which constantly pursue the victim of this delusional condition. Almost every physician of considerable practice has had to deal with many such cases.

Not infrequently I am consulted by mail by patients of this kind. The following is an extract from such a letter:

> DR. MILLS—*Dear Sir:* The writer earnestly requests you, as a physician, to help him in a matter which is to him of *great* importance. When a boy, he was led, by an evil companion, into the degrading habit of self-abuse, which he ignorantly practiced for two and a half years—from the age of fifteen to seventeen and a half years—at which time, learning the evil of the thing, he ceased the practice. But the consequences remain, and now, at twenty-one years of age, he suffers from depression of spirits and physical weakness, produced by the practice. At times, the depression of spirits from remorse amounts to such unbearable anguish that suicide would be a sweet relief. He has practiced great abstemiousness in diet, and takes abundant exercise in open air daily, but has taken no medicine nor ever dared consult a physician, and is unable at this time to pay any respectable physician. Won't you help him by giving him, however briefly, medical advice, and telling him what medicine to take? The present effects physically are nocturnal emissions, and the consequence, *terrible* depressions. Won't you *please, please*, grant this kindness? Please tell him briefly by mail whether medicine will avail, and if so, *what* medicine.

Here you have a true sexual hypochondria, or sexual melancholia. I have been able to do most in these cases by carefully explaining the true nature of the case, and ordering change of scene, and medicines, such as hyoscyamine, hydrobromate, and atropia, for the relief of the emissions, if really frequent. Sometimes oxularia is present, and should be treated with mineral acids, diet, and laxative waters.

Delusional melancholia takes other forms. It may take the form of persecutory delusions, with hallucinations of voices or of sight. Sometimes it is the voice of some one in the neighborhood, calling and threatening; it assumes now one shape and now another; but the patient is able to give no logical reason for hearing the voices or for being the victims of persecution.

Sometimes even the diagnosis of melancholia from mania may be difficult.

The history of this patient, for instance, is as follows: She is 35 years of age and unmarried. Both parents are dead, the father having died of phthisis. One brother died in an insane asylum. She was always healthy as a child. Menstruation is regular. She has had syphilis. For the past eight or nine years she has had, but not frequently, general convulsions. These are probably attacks of epilepsy. In addition to these seizures she has had for the past year spells of despondency. When she has these attacks, she feels firmly convinced that she has committed some unpardonable sin, the nature of which she refuses to state; she thinks that she is going to die and go to hell. These spells last usually for several

days or a week. She had a severe spell in the ward a few days ago, in which she became excited, restless and agitated, walking about the ward, becoming almost maniacal in her manifestations, so that she had to be removed. The cause of this was the terrible condition of mental depression and despondency. Among epileptics you will find illustrations of almost all the forms of insanity according to any classification—mania, melancholia or monomania, and not infrequently, a cataleptoid or katatinic insanity. Here we have an illustration of lypemania or melancholia.

Sometimes, then, as in this case, a patient with melancholia will have attacks of excitement during the course of the melancholia. This patient became excited in consequence of the delusion which was depressing her. She became excited because she feared that she had committed some unpardonable sin, and that she was going to die and go to hell. This so preyed on her mind that she finally got into a condition of intense excitement. This was not mania, although it had the appearance of mania. If at the first visit the patient was found in this condition, the first duty would be to inquire as to the previous condition, in order that the case might be treated properly, for the treatment of such a condition is somewhat different from that of acute mania.

The general points in the differential diagnosis between mania and melancholia, as condensed by Seguin,* are these: In mania, the consciousness is exalted and overacting; in melancholia, it is the reverse, it is depressed. In the one case joy and excitement are the dominating features; in the other, sadness, fear, and religious feelings, often strongly pronounced. In mania, you have incoherent delirium and violent and extravagant actions continuing. In melancholia, you have usually reduced action, and at times absolute immobility. In melancholia often cataleptoid states are present. Insomnia is more common in mania.

A case of mania should not be treated as one of melancholia, and a case of melancholia with an attack of excitement occurring during the course of the melancholia, usually should not be treated as one of mania. Nine out of ten physicians called to a case of melancholia in a state of excitement would diagnosticate the case as one of mania.

Moral treatment will do something for these cases. This woman is improving, for she now thinks that there are probably other people as bad as she is. In treating acute mania, unconnected with any general condition, you would use, for an immediate effect, hyoscyamus, choral or bromide of potassium in large doses; for a more permanent as well as its immediate effect, conium in large doses would be employed. Cases like the one before you sometimes do well on a sedative treatment, but frequently an opposite course is more beneficial. In chronic melancholia, small doses of opium will do a great deal. In cases with excitement, large doses are sometimes beneficial.

One form of hypochondriacal insanity, sometimes called hypochondria and sometimes hypochondriacal melancholia, is more properly, with our present methods of naming and classifying mental disorders, styled hypochondriacal monomania. I have, for example, a patient, a young lady, who has had every tooth extracted, and since has had several painful operations performed on her gums. Her mind has been for years and is now centred upon the thought that she has some disease of her teeth and gums. Competent dentists and surgeons have pronounced her gums healthy, but without effect. Digestive, hepatic, uterine, and other trouble, real and imaginary, are attributed by her to disease of the gums. She reasons about the matter, and shows to her own satisfaction how this symptom and that must originate in her mouth. She is logically depressed, but not in general, emotionally depressed. At times, however, she gets into an almost despairing condition because she cannot get relief, and cannot convince others of her woes.

The following case is another instance of what might be termed hypochondriacal monomania, although the patient eventually committed suicide. J. G. W., aged 62 years, Scotchman, a widower, came to this country about thirty-five years ago. He had good health and steady employment in an office, where, besides acting as a clerk, he handled the goods, lifting them down from and up to the shelves. About 28 years ago he had syphilis. He never was a hard drinker, and for ten years had been a temperance man, having been connected with a temperance society for that length of time. The first time that he noticed anything wrong with him was several years ago, when he jammed his finger between two doors. He said that it did not bleed as it should, and would not heal, but that a material like cobwebs came out of the wound, and up his finger and hand, and from this time on he had been suffering from a discharge from the whole cutaneous surface, and more particularly of his head. The discharge, he believed, was like gum elastic, very adhesive, and when pulled off broke with a snap and curled around his hand, although he said it was invisible to a bystander. He complained of it gathering in knots in his body, and in the night oppressing his head so much that he had to remove the exudation, which was difficult, because it adhered so tightly that it dragged on his scalp. Treatment with the electric brush was tried, but had no permanent effect.

More than fifty per cent. of cases of melancholia recover. The prospect of recovery depends largely upon family history, careful feeding, and good physical conditions.

Incidentally, during the progress of the lecture, I have given a few points as to the treatment of melancholia; and, therefore, will only make brief general remarks. Melancholia, like mania, must be fed, not starved. Milk and eggs should be given in abundance, as should all forms of easily digestible food, particularly animal food. Lime water, pepsin, extract of pancreas, nitromuriatic acid, and bitter tonics, should be given, as required, to arouse and assist digestion. Massage and general faradization will help the patient to assimilate more food, if it does nothing else. Fresh air, with moderate exercise, are important. Stimulants are generally useful, but should not be resorted to as a mere matter of routine. Malt liquors, good rum or whisky, sherry and Burgundy may often be used with advantage.

*Hospital Gazette, August 22, 1878.

Opium is generally more useful than any other narcotic. Deodorized tincture of opium is a desirable preparation, and may often be given with advantage with tincture of digitalis. Granules of aloin are a form of cathartic highly to be recommended.

Bromides may sometimes be used alone, or in combination with opium and digitalis. As yet I have rarely used chloral or hyoscine in melancholia.

Forcible feeding is often of great importance.

Quinine, iron, and strychnia are invaluable in the majority of cases as a continuing treatment.

Preparations of coca have been tried in a few cases with benefit.

Persistent, but not annoying, efforts should be made to amuse and divert melancholiacs.

Medical Societies.

CINCINNATI ACADEMY OF MEDICINE.

Stated meeting, June 30, 1885.

President, Samuel Nickles, M. D., in the chair.

Dr. J. T. Whittaker reported two cases in which he used

Cocaine for the Opium Habit.

Both illustrated the incessant use of large quantities. In the first he practiced gradual, in the second sudden withdrawal. The first on his second return to the habit was treated with cocaine.

The second commenced with the fluid in the form of the tinct. opii, then took the solid form, then the morphia per os, then hypdermically, reaching as high as fifteen grains per day. When he first came under the doctor's care, on physical examination he found five hypodermic syringes. He was an old and successful merchant, who was weak-willed. His family were very sympathetic, and thus his surroundings were very bad. The doctor obtained a competent nurse, and withdrew the morphia at once. This was followed by collapse, mental depression, an attempt at suicide, and colliquative diarrhœa. Was obliged to return to the morphia for a time. Became able to walk about with a cane, but had pains and other uncomfortable symptoms. He went to Louisville to try the faith cure, and imported and supported the faith cure in this city. Later he returned to the doctor. His was a case of intense annoyance, preventing a comfortable night's rest on the part of his physician for a considerable period.

The second case was a lady. Withdrew gradually until reduced to $\frac{1}{8}$ grain. She then improved, and was free from the habit for three years. Unfortunately she was attacked with pneumonia. Morphia was used, and she returned to the habit. She returned to Cincinnati to be cured. Was taking two grains daily. Put her on hydrochlorate of cocaine in the fluid state hypodermically. Gave one-fourth to one-half of the usual dose. Immediate relief followed. There was a sense of comfort in the stomach, and exaltation for one-half hour, when the former ill feeling returned. The second time gave first a 5 per cent. solution, and then a 10 per cent. solution, giving 10 drops, which represesented 1 grain of the latter. The patient immediately arose to a degree of exhilaration. In one or two hours the sensation returned as badly as ever. He was obliged to give $\frac{1}{8}$ gr. morphia hypodermically. Gave the 10 per cent. solution of cocaine as before three times in the next 24 hours. In two hours at the outside would have the desire for morphia again. The patient has had no desire for morphia for two weeks now. The patient is loud in her praises of relief from cocaine.

This, perhaps, ought not to be cited as a case of cure from cocaine, but is certainly a case where much relief was obtained.

The doctor then went thoroughly into the literature of the morphia habit and cocaine. There is paid in India alone $250,000,000 for license fees to sell opium. Richardson and Adams Allen say 100,000 people in the United States eat opium.

A wonderful tolerance in quantity can be established. There was once a preacher who took twenty-five grains of morphia every day. Credé reported a patient who took fifty-two grains every day. The general range of those who indulge extensively is fifteen to sixteen grains per diem. He then described morphinism. The morphia eater goes about in a bent attitude, a peculiar gait, and cast of countenance; later is pale and yellow and changing. The eyes are a peculiar red. The eyes suddenly open with a dreamy look, stare awhile, and close again. Yawning is frequent. Tongue coated. The bowels alternate between constipation and diarrhœa. The patient lacks every capacity. The faculties generally degenerate.

Volley describes three distinct stages—inability, indifference, depression. Profuse sweating forms a prominent symptom. Strychnia, quinine, hyoscyamus, and cannabis indica all have had their trial. The physician is generally deceived by his patient; latter, will maintain that he is not taking morphia when he is. Volley says that it is incurable after five years. The fluid extract of the coca leaves was used five years ago. Cocaine varies from .2 to .02 per cent. in the leaves.

Moerck, of Darmstadt, has immortalized himself with his superior preparation. Coca is one of the oldest remedies in history. Eight million people are in daily use of the coca leaves. The oldest travelers in Peru mention improvement in the respiration, muscles, ideas, and spirits, on the use of coca leaves. The Indians in Peru work at very high altitudes and perform immense labor in the silver mines under the influence of the coca leaves, which they chew as tobacco is here. The priests forbade its use at first, but relented when they found out how much more gold and silver the Indians could bring out of the mines under its use. The leaves were first used in 1758. In 1859 the alkaloid was separated by Niemann. In 1880, its injection hypodermically produced a local area of anæsthesia. 1884 was the era of Koller and Moerck. This year it was first used for the morphia habit, January 3, by Volley. He found it to cause a suffused warmth over the body; the patient lost his depression and exhilaration was produced.

The doctor said he had fashionable ladies come to him to get hypodermic injections of cocaine to make them lively and talkative. He hoped it was needless to tell the Academy that he had always refused. After an injection of cocaine, the pupils dilate in from seven to ten minutes; also widen-

ing of the lids occurs. The union of cocaine and morphia is said to relieve pain entirely.

The reporter thinks cocaine the best remedy for the morphia habit that we have. Straus says he has recovered morphia locked up in the tissues of the body thirteen months after death. This may well explain why relapses occur. The reporter gave his experience with opium smoking in an Arabian coffee house.

Dr. W. H. Wenning reported a case of the morphia habit.

Dr. J. C. Cleveland said his experience had been negative. He thought control of the patient all important. Tea and coffee are good remedies unless the patient is habituated to their use. His results with atropia have been negative.

Dr. C. O. Wright gave his experience in an opium joint. The smoking with him was followed by very unpleasant after-effects.

Dr. M. Cassat related his experience in an opium joint in San Francisco.

Dr. S. Nickles, the president, said: The physiological effects of cocaine are a peculiar physical excitement. This peculiar happiness and joy lasts for a few hours. If the amount taken reaches excess, paralysis intervenes and the patient dies. It is probable that the dose would have to be repeated frequently, and then the cocaine may become just as bad as the morphia. He thought that cocaine acts in no way as an antidote to opium. He thinks it acts only by its action on the cerebrum. He thinks toxic doses of morphia can be taken for years with no disastrous effect. Cocaine will prove an admirable remedy to counteract the depression; nothing but the will of the patient will cure the morphia habit. Did not think morphia remained long in the tissues locked up.

Dr. Philip Zenner thought cocaine a good remedy to ward off the collapse, in the same way small doses of morphia are used. He doubts if it ever acted otherwise.

Dr. Robert Stewart asked if cocaine could be used in case of morphia idiosyncrasy.

Dr. Nickles thought not.

Dr. Whittaker in closing said, morphia remains in the tissues often for a great length of time. Thus we ssmetimes get the effect of a dose weeks maybe after it is administered, and in the same way we may have a return to the morphia habit after a period of abstinence, from the liberation of this locked-up morphia. Recommended warm baths, friction, massage, and alcohol. Spoke of the effect of opium on the appetite. Cocaine gives relief only for the time being.

Stated meeting, June 1, 1885.

Dr. A. G. Denny reported a case of

Double Ovariotomy.

Mrs. R., æt. 30, mulatto, mother of four children, noticed for a number of years pain in the left inguinal region, and for two years a tumor in the same locality. The doctor found later that tapping would be necessary. After this was performed, he noticed in the left ovarian region a tumor the size of an egg, and freely movable. It was necessary to repeat the tappings until they numbered twenty-three, and an aggregate of eighty gallons had been withdrawn. The intervals had gradually shortened, until only eight days occurred between the tappings. When the tumor reached the size of an orange the doctor advised an operation, which was concurred in by Drs. J. L. Cleveland, Geo. E. Jones, and W. H. Wenning. This was refused. Two months later a fatal termination seemed imminent. Dr. P. S. Connor saw her, and advised an operation, which was done. The peritoneum was found largely adherent to the wall. The left ovary consisted of a mass of cysts, varying in size from an egg to a pea, and filled with fluid, attached in many places to the surrounding viscera. These attachments were broken in most instances without any very great difficulty. The right ovary was only one cyst, filled with a caseous substance nearly ready to suppurate. Both pedicles were normal. General peritonitis followed the operation, and death occurred in thirty hours. Only a hurried and imperfect post-mortem was obtained.

Dr. Fred. Kehler examined the specimen, and reported that in his opinion the growths were cystic adenoma of the ovaries.

Dr. Cleveland and Dr. Wenning discussed the case, giving many more points in the history.

Drs. T. A. Reamy, J. T. Whittaker, C. D. Palmer and Joseph Ransohoff, discussed the cases, all maintaining that it was not the ovaries which were at fault, but that the case was one of tubercular peritonitis.

Dr. Philip Zenner reported two cases of

Lead Poisoning.

The one was interesting because it showed the primary stage of this trouble, a stage in which the physician rarely obtains charge. The paralysis merely involved the muscular slip to the tendon of the ring-finger, and the extensor communis digitorum of the right hand. There was no drop-wrist, but the hand was readily pushed down, and there was a tremor present. In the second case there was paresis of the deltoid, causing an inability to lift the arm. Both cases showed the usual symptoms of lead poisoning.

Stated meeting June 15, 1885.

President Samuel Nickles, M. D., in the chair.

Dr. Thad. A. Reamy reported a rare case of

Cyst of the Posterior Vaginal Wall.

The patient was a blonde woman, married, of excellent general health, weighing 150 pounds. Her father had been an exceedingly nervous man. Otherwise there was nothing special in her family or early personal history. At the age of 23, after she had borne one child, she became aware of a tumor lying posterior to the vagina. She consulted several doctors, and was preparing to go east to consult further on the advice of the gentlemen who had seen her, when she found herself again pregnant. This pregnancy ran the usual course without noteworthy occurrence, except that the patient vomited once or twice each day during the whole nine months. This was also the case in the former pregnancy.

She came to Dr. Reamy after the tumor had existed for four years. He found it to be quite large. With the patient in the erect posture, it extended down to the posterior commissure of the vulva. In the dorsal decubitus it retreated two-thirds of the distance up the vagina. The doctor made an exploratory puncture, and was induced to evacuate the tumor at the same sitting. He then explored the sac with the probe, finding it to

be quite extensive, but having no outlet so far as he could discover. The cyst refilled. He again aspirated, and this time curetted the cyst. The patient showed some unpleasant symptoms after the first evacuation. This time she was taken with obstinate pain and uncontrollable vomiting, severe posterior cephalalgia, and partial opisthotonos. It being quite impossible to retain anything on the stomach, she was nourished per rectum for eight days. The symptoms gradually subsided, and the patient is now convalescent. The cyst has not entirely disappeared, and still gives off a slight discharge. Examination of the fluid withdrawn showed the absence of albumen, but the presence of small quantities of the chlorides. The doctor considered the possibility of the tumor being anterior spina bifida, a hematocele, rectocele, vaginal cyst, subperitoneal cyst, and cyst of the broad ligament. Though still quite undecided as to diagnosis, yet he was of the opinion that it was the latter. He then reviewed the scanty literature on the subject, mentioning the two cases reported by Thomas in the March number of *Gaillard's Medical Monthly*, 1885, and a case of Emmet's, reported in the last edition of his system of gynecology.

Dr. C. D. Palmer spoke of the extreme rarity of cysts of this nature; all opinions he thought must be more or less speculative, unless it was that of the gentlemen who had had the opportunity of close observation. He was inclined to think that the trouble in question was anterior spina bifida.

Dr. E. G. Zinke reviewed the German literature on the subject, which he found not nearly so meagre as the English. He thought the case reported must be one of a cyst of Gärtner's ducts.

Dr. P. S. Connor thought the doctor anticipated too much trouble. He should wait till patient had improved, and cauterize the cyst well.

Dr. J. T. Whittaker was of the opinion that some of the severe symptoms were hysterical.

TRANSACTIONS OF THE CHICAGO GYNECOLOGICAL SOCIETY.

Friday evening, 29th May, 1885. Regular meeting.

The society was called to order by the President, Dr. H. P. Merriman.

An inaugural thesis, entitled,

The Normal Position of the Uterus, and its Relation to the other Pelvic Organs,

was presented by Franklin H. Martin, M. D. (Chicago Medical College, 1880), and read by the Secretary, Dr. Edward Warren Sawyer.

The extreme theories of Schultze, Fritsch, and Savage were opposed for the following reasons:

1. In extreme anteversion, the wave impulse would strike the posterior broad surface of the body of the uterus, and drive it down upon the bladder and anterior wall of the vagina, while, on the other hand (the perpendicular theory of Savage), the anterior broad surface of the body would receive the impulse to an equal disadvantage, displacing the uterus backward and driving the cervix downward, while if the uterus occupied the position between these two extremes, the narrow crest of the fundus would receive the impulse in the line of the axis of the uterus, and all the force would become equally distributed through all of its supports. Here, too, the organ would not so directly receive the whole impulse, as it would be equally dispersed upon its sides and the posterior ligaments and anterior supports, and its lateral attachments would receive, to an equal extent, their portion of the impulse.

2. The manner in which the bladder collapses, to our mind, precludes the possibility, or at least the probability of the uterus occupying normally the position of extreme anteversion. The bladder, when collapsed, or when empty, is a triangular-shaped body—not flat like a plate—the base corresponding to its peritoneal surface, the apex corresponding to the urethra. The posterior or inferior surface corresponds to the anterior wall of the vagina, to which it is intimately attached; the anterior wall corresponds to the symphysis, to which it it is loosely attached. It is readily seen, then, that the bladder distends only in the direction of the peritoneum, or its one free surface. According to the extreme anteversion theorists, the free surface of the bladder and the uterus are in apposition. If such be the case, the uterus changes its position constantly, as the bladder normally relaxes or contracts—this seems to us very improbable. We believe that this space is usually filled with the light coils of the small intestines.

3. The broad ligaments receive their external attachments at a point about equidistant from the centre of the sacrum posteriorly, and the pubic junction anteriorly, in such a way as to divide the plane of the brim of the true pelvis into about equal halves. If the body of the uterus occupies a position in the centre of the pelvis on a direct line with the ordinary attachments of these ligaments, which it is at least rational to believe is the case, it occupies a position between the perpendicular of Savage, and the extreme anteversion of Fritsch.

4. With extreme anteversion, the cervix, with the fundus occupying a position behind the symphysis, would necessarily have to occupy a position far back in the pelvis, within three-fourths of one inch of the sacrum—with a normal conformation of parts, this is impossible without interfering with the rectum.

5. If we take the measurements of Foster and Litzmann into consideration, we can at once demonstrate the impracticability of the position given by Savage—*i. e.*, the perpendicular. The cervix occupies a position, normally, at a distance of one and one-half inches from the sacrum, the rectum intervening. It is impossible for the uterus to assume anything like a perpendicular with the cervix in this position, on account of the anterior curve of the sacrum above, which necessitates an anterior version from the perpendicular of at least fifteen degrees.

DISCUSSION.

Professor W. W. Jaggard was pleased with the selection of the topic, and its mode of treatment, but did not agree with Dr. Martin in all his conclusions.

Bandl had made a correct statement of the diversity of opinion upon this subject, in his essay on "*The Normal Position and the Normal Re-*

lationship of the Uterus, and the Pathologico-Anatomical Causes of the Symptom of Anteflexion," (*Archiv. für Gynœkologie*, Band. xxvi., Heft 3, 1884,) read before the Gynecological Section of the *Versammlung deutscher Naturforscher und Ærzte* in Freiburg, September, 1883.

"In the course of time, almost every position of the uterus, with the exception of prolapse, has been accepted as the normal by different anatomists and gynecologists, and particularly by the more eminent ones."

Köllker (1882), from a series of examinations of the cadavers of girls, from ten to eighteen years old, has concluded that the uterus is not bent, nor curved upon itself, but is straight, and that its long axis corresponds with the principal axis of the small pelvis. Its position is variable within certain limits, depending upon the condition of the bladder and rectum. This opinion coincides closely with judgments of Kohlrausch (1854), Le Gendre (1868), Freund, Carl Braun (1857), J. Marion Sims (1855), Langer (1881). Professor Paul F. Munde, in his recent excellent work on "Minor Surgical Gynecology," favors these views to the extent that he says, "with the woman in the recumbent position, the examining finger is unable to touch the body of the uterus before or behind the cervix, if the uterus is normally situated'.'

Bandl, in the paper to which allusion was made, confirms Köllker's view. The evidence he furnishes is of a high order. His methods of investigation were:

1. The attentive examination of living women.
2. Examination and observation before and during the operation of laparotomy.
3. The bi-manual examination of the organ in cadavers, before and after abdominal section.
4. The comparative anatomical examination of many *uteri*.

Dr. Philip Adolphus thought, with Emmet, that "there is no common standard by which to determine the proper position for the uterus in all women, but that in each individual there is a point, or plane, in the pelvis which the uterus should occupy when she is in a state of health and not pregnant." He referred in detail to Emmet's "normal or health line," and to the pathological character of displacements above or below this line. It was a matter of relative insignificance whether or no the long axis of the uterus coincided with any particular pelvic axis.

In the concrete case, the sensations of the individual would indicate a normal or abnormal position.

Professor Daniel T. Nelson said the uterus was fixed in a position of unstable equilibrium by the annular and other ligaments. It could move to a certain degree in every direction, and return to its original, normal position. Displacement above or below Emmet's "health line" was productive of symptoms, if the uterus remained fixed in such a position, as was usually the case when violence caused the dislocation. Departure from the principal axis of the pelvis was of comparatively insignificant moment, viewed absolutely. The vagina and perineum are not primary supports of the uterus, and only assume this function when, as the result of the relaxation of the proper uterine supports, the organ is displaced downwards. This secondary character of the vaginal and perineal support was capable of demonstration by the examination of a woman in the erect attitude. Upon coughing or sneezing, the uterus would descend and receive support from vagina and perineum, only to regain its original position when the excitant was removed. This remark applied exclusively to normal organs in normal position.

He wished to emphasize the statement that the rectum was not the normal receptacle for the fæces. Anatomy and physiology teach that in the normal condition the gut is empty up to the sigmoid flexure. The sigmoid flexure is a sort of valve to retain fæces.

He narrated the history of a case of retention of urine in a puerperal woman, in which the bladder was displaced towards the left iliac fossa, while the uterus was directed towards the right. He would like to ask the Fellows if this displacement, observed in a single case, corresponded with their observations.

Professor Charles Warrington Earle related the history of a case of retention of urine in a puerperal woman, the bladder displacing the uterus upwards and backwards. Upon the introduction of a catheter, four quarts of urine were evacuated, and the pelvic viscera returned to their normal relations.

Dr. Edward Warren Sawyer said the uterus had great latitude of movement antero-posteriorly and laterally; elevation above or depression below the normal plane, even to a slight degree, was productive of pain. The introduction of a pessary, which merely elevated the uterus when partially prolapsed, without altering flexion, was sufficient in many cases to afford complete relief.

While a student in the Medical Department of Harvard University, he had taken plaster casts of the vagina. Such casts were of uniform shape, while they differed in size. They were curved, convex posteriorly, concave anteriorly. They were never shaped like an S. The curve did not correspond to that of the anterior surface of the sacrum, but to the floor of the pelvis.

Dr. H. T. Byford thought Dr. Sawyer's experiments were faulty. When plaster of Paris was injected into the vagina, with the rectum empty, the vagina would act exactly as the rectum would under similar conditions.

The President, Dr. H. P. Merriman, complimented the author of the paper on the careful, judicial mode of treatment of his difficult subject.

He agreed with Dr. Adolphus, Dr. Nelson, Dr. Sawyer, that elevation above or depression below a certain horizontal plane was of greater importance, in the production of symptoms, than deviation from the principal pelvic axis antero-posteriorly or laterally.

The normal position of the uterus was as variable as the quantity of blood lost at a menstruation. Every woman was a law unto herself. He referred in detail to Robert Barnes's theory of uterine support, and concluded by recommending Bozemann's plan of columning the vagina, when a hard-rubber pessary could not be borne.

Professor Christian Fenger, M. D. (Copenhagen, 1867), and Franklin H. Martin, M. D. (Chicago Medical College, 1880), were then elected Fellows of the Society.

Periscope.

A Case of Syphilis, in which Ataxy and other Nervous Disorders Occurred at an Unusually Early Period.

Dr. T. Churton thus writes in the *Brit. Med. Jour.*, June 27:

John P., aged 24, of medium size, light hair and complexion, normal weight 11 stone 6 lbs., but now reduced to 10 stone, a groom, able when in health to ride any horse, to walk thirty miles a day, and to endure long abstinence from food, accustomed to drink rather heavily both of beer and spirits, was admitted into the Leeds Infirmary on December 19, 1884. He was quite unable to walk; he could stand, even when supported on both sides, with great difficulty, anxiously looking down all the while at his legs, and so tending to fall forwards, being unable to balance his trunk upon his lower limbs. He had also lost power of coördinate movements in his upper limbs; could not cut up his food; could not even pick up a match without great trouble and bungling; he could not, moreover, tell by mere sense of touch what the match was. His grasp was, however, not very feeble; he complained of numbness and "pins and needles" in his fingers, especially in those of the left hand. He had similar abnormal sensations in his feet, especially in the left. His replies to questions were hazy, and, when repeated, variable; he seemed rather dazed. There was no tenderness nor swelling of bones and joints; no special wasting of muscles. The plantar and patellar reflexes were absent; the cremasteric and abdominal present; the pupils, optic discs, and retinæ were normal. Hearing, etc., was not notably altered. The urine, on being heated, gave a marked phosphatic cloud. The organs of supply, circulation, and elimination were not particularly affected; he stated, however, that he had suffered a few weeks previously from epigastric and abdominal pains, with some giddiness. In the right groin was a dusky red scaly rash; on the inner side of the right thigh was a similar, but much larger patch; on the penis, a cicatrix was found.

At first denying syphilis, he subsequently gave the following history. At seven years of age he had rheumatic fever, but no other illness until two years ago, when he had gonorrhœa; sixteen weeks ago he had a chancre, followed by an enlarged gland in his left groin; three weeks later, he had a sore throat and a rash on the neck; he was then treated for syphilis, but not continuously. His parents are alive, but ailing; in his family there is neither nervous disease nor phthisis. Five or six weeks ago his right toes began to be numb and tingling; he staggered when he walked; the numbness spread up the leg; then the left foot and leg became affected; he was obliged to look at his legs when walking; he could not stand with his eyes shut or in the dark. At this time he was still drinking rather freely. A fortnight ago (December 5) he was quite unable to walk. Ten days ago his hands became numb and weak.

Upon this history being gained from him, mercurial inunction was at once begun; one drachm of blue ointment being rubbed in daily. He was kept at rest, had good food, and no alcohol. He improved rapidly, so that on January 10 he could walk fairly well, could stand for a few moments with closed eyes, could cut up his food, grasp the dynamometer (right 53, left 51), distinguish two points of the æsthesiometer on the finger-tips at a quarter of an inch from each other, and at one inch distance on the instep. The plantar and patellar reflexes were still absent. The inunction was continued until January 17. He was discharged almost well on the 21st. A month later, the reflexes were normal.

Though the leading and most prominent clinical features of this case were finally seen to be those of locomotor ataxy, or posterior sclerosis, it cannot be taken as a simple case of that disease. The patient could neither walk nor stand at all, eyes shut or eyes open; so that, though he looked constantly at his legs when supported in the erect position, the sight of them did not help him. The equilibrating organ could not avail itself of information, reaching it through any channel. The really noteworthy feature of the case, however, is beside its accurate pathology. For the patient, having been quite well four months previously to admission, and having then contracted syphilis, presented distinct symptoms of serious nervous disorder two months afterwards. I have previously seen nothing so rapid as this, except upon a single occasion.

Some years ago a similar case came under my observation. A young man, within a few months of his having contracted syphilis, presented, in addition to complete ataxy, certain specific signs which John P. did not present—for example, paralysis of the third nerve on one side. In him, perfect recovery ensued upon the very vigorous use of mercurial treatment, moderate treatment having been found wholly ineffective. Some authorities state that nervous diseases due to syphilis are not to be expected until from three to eighteen years have elapsed since the syphilis was acquired; but neither are changes in the arteries expected until after an equal lapse of time, yet cases have been recently recorded by Dr. Sharkey and M. Leudet, in which arteritis has followed the original sore in a few months. Now this question of the lapse of time appears to be one of some importance, for I do not remember ever to have seen a case of ataxy occurring many years after even indisputable syphilis, in which strong antisyphilitic treatment has done any good whatever; early cases, on the other hand, seem to require very decided treatment. The reason why later cases are unaffected by that treatment has appeared to me to be that, during the interval, other causes of disease, perhaps several, or even many, have come into operation, and, aided to some extent by the specific taint, have brought

about a condition of the nerves and sheaths which the syphilis alone had shown itself, even when in full vigor, unable in these persons to achieve. In such circumstances, no simple treatment, no single drug, no one precaution, is sufficient, or scientific, or in accord with common sense. It has been shown, indeed, that even such compositely caused disorders are not, when treated early, at all hopeless. But the case now under consideration is one of syphilis affecting, at an unusually early period, motion slightly, and coördination of sensations and movements gravely. Such cases appear to be as easily curable by vigorous treatment, specific and otherwise, as the commoner form of localized paralysis, due to a simple gumma.

Diabetic Neuralgia.

Cornillon (*Revue de Méd.*, Paris, March, 1884), after passing in review the writings of Dreyfous, Worms, Drasche, and others on the subject, relates two new cases of his own, in which cervico-brachial neuralgia, first on the left and then on the right side, and symmetrical sciatica, were evidently owing to the saccharine condition of the blood. Such cases are, on the whole, rare, as until now only twenty-two are on record. On analyzing these, it is found that glycæmic neuralgia is not generally an initial symptom of diabetes, but occurs rather when this condition is confirmed, and when there are much loss of power, emaciation, and polydipsia. It comes on quite suddenly; the patient goes to bed apparently as well as usual, and is suddenly wakened up by a fearful attack of pain which drives him out of bed; or the pain comes on on waking in the morning, after a somewhat restless night. It is continuous, terebrating, or lancinating, or lightning-like, and there are occasional paroxysms which exceed in keenness and duration the most violent exacerbations of other forms of neuralgia. These attacks occur three or four times a day, after meals, and again on going to bed. The pain is so violent that one of Worms's patients threatened to commit suicide; one of Drasche's ran about in his room yelling and screaming. The nocturnal attacks appear to be worse than those which occur in the daytime. One of Cornillon's patients did not go to bed for several months, from fear of the heat of the bed bringing on a bad attack. The pain is sometimes localized in the course of certain nerves; at other times it will also affect the muscles and bones. Digital pressure on the course of the nerve increases it, while compression all the way round rather relieves it. There is generally no fever, the skin is cool, the pulse normal; Buzzard, however, has seen a slight elevation of temperature, which is quite exceptional. If the pain continue for any length of time, there are loss of sleep and appetite, and great depression of spirits; but on the disappearance of the pain the patients recover themselves rapidly.

One of the most striking features of diabetic neuralgia is its symmetry. This was seen in eighteen cases out of twenty-two. It is, however, rarely at once symmetrical; more frequently one limb is first affected, and its fellow only follows suit a few days afterwards. The same nerve-fibres are then affected, the distribution being quite regular. The pain, however, is generally worse in one limb than in the other; and mostly so in the one that was first affected. In Drasche's case it was bi-hemiplegic, in this way, that it was first perceived in the right leg, then proceeded to the arm, forearm, and fingers of the same side; after a time the lower and then the upper limb of the opposite side was affected; and in one of Cornillon's cases it alternated so that at first the left cervico-brachial plexus suffered, and some months afterwards the same plexus on the other side. The quantity of sugar in the urine was in most cases large when the neuralgia appeared; in a few, however, only minimal. In general an anti-diabetic treatment, by alkalies and diet, rapidly relieved the suffering, and the improvement went *pari passu* with the diminution of sugar. The attacks occurred then more rarely, and were less severe; but if the patient broke the regimen, the pain would return in its old intensity.

The prognosis is, therefore, rather favorable, if the true nature of the disease be recognized; but if it be not properly understood, the muscles will gradually waste away, and anæsthesia of the skin sets in, which proves intractable.

The diagnosis does not present any great difficulties. It should, however, be recollected that not every neuralgia which occurs in the course of diabetes is of glycæmic origin. Where it is independent of the glycosuria, it may be owing to carious teeth, when it affects the dental nerves; or to cold, fatigue, etc., and then selects those parts which have been principally exposed. Such neuralgia is generally unilateral, the attacks being of medium or even slight intensity; and the pain generally yields in a few days to ordinary treatment. On the contrary, where glycosuria is the cause, the neuralgia appears suddenly and without any appreciable exciting cause; there are three or four long attacks during the day, and the pain is intolerable; it is mostly symmetrical, and invades more particularly the sciatic plexus. It resists the ordinary treatment by morphia and salicylate of soda, and yields to anti-diabetic treatment only. Saturnine neuralgia is also symmetrical; but it has a different history, and the urine does not contain any sugar.

Rosenstein considers the diabetic neuralgia, as well as the glycosuria, to be owing to venous congestion in the abdominal organs; but this theory is unacceptable, as then sciatica would be much more common than it really is, and it would also habitually occur in persons suffering from piles, chronic nephritis, tumor of the spleen, congestion of the liver, etc.; such, however, is not by any means the case. Moreover, diabetic neuralgia occasionally affects the brachial plexus, the intercostal nerves, and the fifth pair. Worms, on the other hand, considers the excessively saccharine state of the blood to be the cause, whereby he thinks that an anatomical or dynamic modification of the nerves is produced, just as in gout and lead poisoning. This explanation is accepted by Drasche and Peter; but it is refuted by the circumstance that in some cases there is only a minimal amount of sugar in the urine, and the preceding symptoms of diabetes, such as polydipsia, emaciation, loss of power, etc., have only been slight. Cornillon is of opinion that diabetic neuralgia is owing rather to the presence of uric acid

in the blood, since most patients have had gouty or rheumatic antecedents, and sciatica is a somewhat common symptom of gout. As for any pathological lesion in the nervous system, it is evident that we have not to do with neuritis; for there is no pyrexia, no vesicular or pemphigoid eruption, no paralysis: on the other hand, the fact that this form of neuralgia is very obstinate, and affects homologous nerves, tends to show that there must be a temporary, although not extensive lesion of the spinal cord. In what part of the spinal centre it may be situated, whether in the membranes near the posterior columns, or in the white or gray matter of the cord itself, it would be premature to say, as no necropsy has as yet been made.

Perforating Ulcer of the Bladder.

Dr. James Oliver thus writes in the *London Med. Times*, July 18th:

The type of ulcer I am about to describe as affecting the bladder, has hitherto been looked upon as more or less peculiar to the stomach and duodenum. When, however, we consider the probable cause of its formation, it is not to be wondered at that other parts of the intestinal canal, and even the bladder itself, may become the seat of a similar necrotic change. In the *Lancet* of March 7th of this year, I recorded a case in which the ascending colon had been thus perforated, and doubtless careful pathological observation will prove that such are not uncommon.

Perforating ulcer of the bladder is primarily always acute; if, however, there be extensive destruction of tissue, the functions of the organ are likely to be permanently disturbed, and the disease to become one truly chronic in character. This ulcer is especially apt to recur, a fact strongly in favor of a diathetic tendency or proneness to the affection. It usually develops without signs of inflammation or suppuration, and as in the stomach and other parts of the intestinal tract, apparently results from a plugging of the vessels which run in and nourish the coats of the viscus. If the blood supply to any tissue of the body be suddenly withdrawn—as happens when a vessel becomes occluded—and collateral circulation be not readily established, death of the part is inevitable. Embolism and thrombosis are the most frequent causes of softening in the brain and spinal cord, and it is more than likely that these play an important part in the production of perforating ulcer of the bladder. Round ulcers, similar to those we are now considering, have been produced in the stomachs of animals artificially by the introduction of emboli into the gastric vessels. This form of necrosis is truly analogous with dry gangrene occasionally seen in the extremities of the aged, where the arteries, because of the degenerative changes in their coats, have become impervious. The embolic theory of chorea is still tenable, and all who see much of this disease remark its frequent association with rheumatism or a rheumatic predisposition. Judging from those cases of perforating ulcer of the bladder which have come under my notice, I am inclined to believe that the rheumatic diathesis augments the tendency to this affection, and favors embolism as a probable cause of its production. In one case the symptoms attributable to perforating ulcer developed during an attack of acute rheumatism, and as the patient died some time after, opportunity was afforded for examining the bladder and verifying the diagnosis. The heart in this case showed no trace of valvular disease. Females, it would appear, are more prone to this affection than males, and especially about the period of puberty. No exciting cause can as yet be suggested.

One or more ulcers may develop, according to the number of vessels occluded; some days, however, must necessarily elapse before disintegration is completed. Whether the necrotic change shall invade the whole thickness of the bladder wall or not, depends on the seat of obstruction of the artery, the completeness or incompleteness of the plugging, and the period at which collateral circulation becomes established. Should, however, the destructive process attack all the coats of the bladder, and at a part covered by peritoneum, this coat tends to thicken and form adhesions with neighboring structures, it may be the small intestine or omentum, thereby preventing rupture of the organ, extravasation of its contents, and death by shock or peritonitis. If the bladder forms adhesions with any part of the intestinal canal, the ulcerative process may extend and invade this organ too; vesico intestinal fistula, though fortunately rare, may therefore depend upon simple perforation. In such cases even a careful inquiry into the clinical history may fail to reveal the probable starting-point.

The symptoms and course of perforating ulcer of the bladder are usually very insidious, and fatal peritonitis may result from destruction of all the coats ere the grave condition has been recognized. Pain more or less constant and referred to the hypogastrium is a frequent symptom—it is aggravated by pressure and any slight distension of the organ. There is frequency in micturition, and the pain, as a rule, becomes sharp and cutting in character towards the end of the act. The most distressing symptom of all is tenesmus, which results from spasm of the muscular coat, and may continue for some time after the organ has completely emptied itself. Blood usually appears in the urine about the third or fourth day, is small in quantity, and is expelled with the last drops of urine. The treatment is rest and bland food; opiates must be given to relieve pain and the intense bearing down.

Control of the Lacteal Secretion.

Dr. J. Stuart Nairne thus writes in the *British Medical Journal*, June 27, 1885:

The breasts of parturient women frequently give trouble from engorgement of the lactiferous vessels, and from other causes leading to tension and pain in these organs. The two following cases will illustrate the line of treatment I have followed for some years past under these circumstances, and which has never yet failed to afford me perfect satisfaction, and my patients perfect ease.

Case 1. Mrs. G., multipara, was confined of a dropsical and malformed dead child, at full time, on March 14, 1885. The breasts, which had been small and hard before confinement, soon became

engorged and swollen; and the patient was hot and feverish. Cloths moistened with whisky and vinegar were laid on the breasts, and ten drops of the tincture of belladonna were given every hour. Within twenty-four hours, the throbbing, which had been very troublesome, had ceased; milk could be easily expressed from the nipples, and she complained of a very dry throat. When the throat began to become dry, the number of drops of the tincture was diminished. During ten days she had this treatment; the last few days, ten drops only three times a day; and by that time the milk had almost entirely disappeared, and the breasts were small and flaccid. They gave no further trouble.

Case 2. Mrs. C. was confined of her second child on May 25, 1885; it was very weakly, being born before its time. She had a rapid rush of milk to the breasts; and next day these organs were very much enlarged, tender, and hard, and the child could draw no milk from them, and was so weakly that I thought it would die. It was, therefore, fed with a spoon, and the tincture of belladonna was given internally, as in the first case. The breasts were supported, and gently rubbed from the circumference towards the nipple. Next day, she said she felt hardly any pain, and the milk could be easily expressed from the nipples. The belladonna was continued another day, by which time the breasts were so soft, and the milk was flowing so freely, that the child was quite able to take its own nourishment. The belladonna was then stopped, and the breasts have given no further trouble.

These are only two cases which I have described, because they have just occurred, and they point quite clearly to the powerful influence that belladonna has in modifying the secretion of milk. Of course, one might say that, after a few days, the breasts settle down of themselves to their work. Sometimes they do, and sometimes they do not. My observation points to the fact that poor women, of their own accord, fly to a hundred remedies to relieve them—seidlitz powders, castor oil, rubbing with oil and various things, and exhausting the breast with some kind of apparatus, and frequently to no effect; and frequently, also, with no result, is belladonna applied externally. The worst suppurating breast ever I saw was one in which the extract of belladonna had been applied most faithfully. In fact, applied externally in any form, belladonna is most disappointing. It frequently fails to relieve pain, take out the heat, or reduce the secretion of milk; and the cleanest of its applications is dirty. The smell, too, is frequently exceedingly offensive to the patient. Belladonna given internally is at once cleanly and effective; and I believe that, administered with judgment and careful watching of its effect, it is a specific for such congested conditions of the mammary organs.

Latent Vesical Calculus.

Before the West London Medico-Chirurgical Society (*Med. Times*, June 13), Mr. Fenwick pointed out that stone in the bladder was frequently overlooked because calculous symptoms were absent owing to (1) anæsthesia of the mucous membrane of the bladder, well exemplified in a case mentioned in Deschamps' "Traité de la Taille," Vol. I., p. 166; or (2) mechanical causes preventing the stone falling upon the sensitive neck of the bladder. These mechanical conditions were of three kinds—(1) adherence of the calculus to the walls of the bladder; (2) sacculation of the bladder wall (both rare conditions); and (3) pouching of the *bas fonds* of the bladder. He drew attention particularly to this last cause, which was generally supposed to be a condition inherent in old age as a consequence of enlarged prostate, but which was also produced by stricture of the urethra in the adult. It consisted in the hypertrophy of the muscles of the ureters, commonly known as the muscles of Ellis, which cross the base of the trigone from ureter to ureter. The *bas fond* is pouched behind this ridge or bar, and the small pool of stagnant urine which collects there tends to produce or augment the size of a stone, like the similar collection in the pouch of the aged bladder behind an enlarged prostate. Moreover, it is obvious that this ridge is as able to prevent the stone contained in such a pouch from galling on the neck of the bladder as is an enlarged third lobe of a prostate. A case illustrating the latency of stone due to this cause was then detailed, and the bladder with the above-mentioned ridge or pouch exhibited. It had been removed from a man, aged 35, who had suffered for eighteen years from traumatic stricture, and had been under notice for the last nine months for chronic cystitis, stricture, and right-sided nephrosis. A month before his death he exhibited symptoms of calculus, and was immediately sounded. A large stone was discovered and removed at one sitting, weighing $1\frac{3}{4}$ ounces; he died fourteen days after the operation. Mr. Fenwick mentioned that four out of thirteen cases of calculus which had passed through his hands during the last quarter fell into the category of latent stone. In one of these four cases a stone weighing over a pound and a half had been successfully removed by his colleague, Mr. Rivington.

Mr. Swinford mentioned a case he had seen when at University College Hospital, where lithotomy had been decided upon, but at the moment of operation it was abandoned, as the stone could not be felt. The patient died soon after, and a stone was found encysted in his bladder.

Dr. Thudichum mentioned that encysted calculi were generally of renal origin. He reproached surgeons with not paying sufficient attention to the medical side of their cases, and it was to be attributed to this that so little was known as to the causation of stone.

Mr. Bruce Clarke quoted a case where the symptoms of stone only presented themselves when from any cause the urine ceased to be acid, and became alkaline; further, the symptoms were oftener in abeyance with uric acid calculi.

Dr. Campbell Pope mentioned the case of an infant at whose birth he was present, who did not pass any water for the first two days, and who, notwithstanding all efforts made to relieve it, died subsequently, and where at the post-mortem both ureters were found to be quite impervious, thus showing at what an early age the causes of stone might begin.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint entitled "The Latest Systems of Medicine," Dr. J. C. Reeve, of Dayton, Ohio, gives a valuable historical review of the rise and fall of special systems in medicine. In passing, he touches up the homœopaths and the bacillomaniacs.

——Prof. J. B. McConnell, M. D., of Montreal, has published a useful pamphlet on cholera, giving a great deal of information, in small space, about its nature, symptoms, history, causes, and prevention.

——The obscure subject of hydatid tumors in the brain is handled in an interesting manner in a pamphlet before us by Dr. R. Harvey Reed, of Mansfield, Ohio.

——Messrs. Cupples, Upham & Co., of Boston, have published in handsome form a pamphlet of twenty four pages by Dr. Buckminster Brown, entitled, "Double Congenital Displacement of the Hip; Description of a Case, with Treatment Resulting in Cure." It is accompanied by several well-executed photographic plates, and the case is certainly an extraordinary one, and worthy of this careful description.

BOOK NOTICES.

Eighth Report of the State Board of Health of Wisconsin. Pp. 158. Madison, Wis. 1885.

This volume contains the general report of the Board, that of the Secretary, extracts from correspondence, a rather premature announcement of the contagion of consumption, an article on milk by Prof. Daniels, and one on the conduct of funeral services in death from contagious diseases by Rev. E. Corwin.

The Technology of Bacteria Investigation. Explicit directions for the study of bacteria, their culture, staining, mounting, etc. By Charles S. Dolley, M. D. 8vo., pp. 263. Price, $2.00. Boston, S. E. Cassino & Co., 1885.

To many investigators this work will be a welcome aid in their researches. It begins with directions for microscopical preparations and culture experiments, and for experiments in vaccination or inoculation. A second part is devoted to the special methods for investigating pathogenic bacteria, as those of anthrax, cholera, glanders, syphilis, tuberculosis, etc., including all the diseases which owe, or are imagined by some to owe, their origin to bacteria. In the last part are given a large number of recipes for the preparation of preserving and staining fluids, and other formulæ of service to the microscopist.

As a hand-book in investigations of this character, it appears to us to be the most complete which has yet been issued on this side of the Atlantic.

The Treatment of Opium Addiction, by J. B. Mattison, M. D. 8vo., pp. 49. Price, 50c. G. P. Putnam's Sons, New York.

The author details his method of breaking up the opium habit, and claims that it is vincible in all cases where not connected with organic disease. The monograph is an enlargement of a paper read before the American Association for the Cure of Inebriates.

Elements of Modern Medicine, Including Principles of Pathology and Therapeutics, with many useful memoranda and valuable tables for reference, by R. F. Stone, M. D., etc. D. Appleton & Co., N. Y.

As indicated by the title, this is an epitome, compendium, or remembrancer, for the student and physician. It is printed in small type on thin paper, and bound like a pocket diary for convenience of carrying. For those who need this sort of book, it can be recommended as carefully prepared, and containing a great deal of matter.

Diseases of the Tongue. By Henry T. Butlin, F. R. C. S. Pp. 451.

Comparative Anatomy and Physiology. By F. Jeffrey Bell, M. A., etc. Pp. 555. Lea Bros. & Co., Philadelphia.

These two excellent works are parts of the "Clinical Manuals for Practitioners and Students of Medicine," issued in Great Britain and published in the United States by Messrs. Lea Bros. They are exceptionally excellent in composition, convenient in size, well illustrated and printed, and nicely bound in cloth.

The two volumes before us are fully equal to their predecessors, and will be found a valuable addition to a medical library.

Cancer: A Study of 397 Cases of Cancer of the Female Breast, with clinical observations. By Willard Parker, M. D. 8vo., pp. 73. Price, $1.50. G. P. Putnam's Sons, New York city.

The editor, the son of the late Dr. W. Parker, informs us that this monograph was the last medical study of his father, and it was his wish that it should be published. It is certainly a valuable record, and with its full tables and sound suggestions for treatment will aid the practitioner materially in combating this dire disease.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE FAILURE OF THE VIVISECTION BILL IN PENNSYLVANIA.

The Pennsylvania branch of the American Society for the Restriction of Vivisection has lately distributed several tracts and pamphlets in pursuit of its aims, and to influence the public in favor of its efforts. One of these is entitled "Facts in regard to the failure of the bills presented to the Legislature for the restriction of vivisection." The brunt of this statement bears heavily on Drs. H. C. Wood and S. W. Mitchell. They are accused of having promised the Society to support a bill which, before the legislative committee, they threw cold water upon.

A careful reading of the "statement of facts"—and we have not sought other sources of information—will easily explain the position assumed by these gentlemen. Both of them, and for that matter all physicians, are perfectly willing to support a bill restricting vivisection, provided that a sensible restriction being admitted, the matter will end there, and no further agitation be begun to do away with it altogether. This was the assurance Dr. Mitchell asked, and that the Society did not give. They say their committee was not prepared for the question. We ask, are they prepared now to give an affirmative reply? We have good reason to know they are not. We have excellent authority for saying that the Society intend to continue to agitate and appeal, with the hope of abolishing vivisection entirely. This is evident from their pamphlets, as well as their spoken utterances. Their name, "for restricting vivisection," is merely a disguise for their real intentions, and not an honest intimation of their final purpose.

Such being the case, all must approve of the action of the gentlemen named. They did not intend to commit themselves to the projects of a society which declined to express its real designs, and merely wanted to use them as stepping-stones to results which they condemned.

While disapproving of causing unnecessary pain to any organic creature, we acknowledge but little sympathy with the sentimental affection for brutes now so prevalent. To a well-ordered

mind no sight is less pleasing than to see a woman fondling and kissing some ugly cur of high degree, when her own children are lacking in physical or moral education, or when she is taking nightly precautions not to have children—and this sight is no rare one in our civilization.

THE FUNCTION OF THE THYROID GLAND.

Most works on physiology pass over the thyroid gland with a very superficial mention. It is said to exercise some part of importance in fœtal life, no one knows what. In extra-fœtal life it is said to partially atrophy, and to be merely a useless organ to the adult—rather worse than useless, as in goitre it becomes inconvenient, and sometimes dangerous.

This shows how little we know about human physiology. Recent researches have shown that the thyroid gland has an intimate and all-important relation to the highest functions of man, those of his brain. This fact was first developed by the extirpation of the gland in goitre, a proceeding which, according to the received views, ought to be wholly indifferent to the economy. Such is far from the case. After the total extirpation of the gland, the subjects steadily lose their mental vigor; the features become heavy; the speech slow and dull; the muscular system weakens, and the skin turns rough, thick, and hard; in short, a condition gradually supervenes strikingly like that called by Charcot *myxœdema*, or the pachydermatic cachexia. They become *cretins*.

If ever so little of the gland remains, it is sufficient to prevent these changes; but its complete removal surely entails them. Experiments on dogs and cats yield similar results. The animals do not long survive, but are attacked with convulsions, somnolence and paralysis, which prove fatal.

Two theories have been advanced to explain these changes. One is that of Liebermeister, who maintains that the thyroid gland is the regulatory organ of the encephalic circulation, and that its abstraction throws this into chronic disorder. The other is that of Prof. Bruns, of Tübingen. He believes that the thyroid is either a depuratory gland which excretes certain substances poisonous to the nervous system; or that it fabricates certain substances indispensable to nervous vigor—which of the two he is uncertain.

The very important practical conclusion remains uncontested, that in all operations for goitre, a small portion of the gland should be allowed to remain.

POISONOUS QUALITIES OF SULPHUROUS ACID.

In indigo manufactories and straw-bleaching establishments, and in similar institutions, it has long been known that the air impregnated with the vapors of sulphurous acid is very injurious to inhale. But the question, what percentage of admixture of the acid to the atmosphere becomes dangerous to the human being, though settled long since with reference to carbonic oxide and carbonic acid, has never been determined as regards sulphurous acid.

Dr. Masonori Ogata, in Japan, has recently inquired into this point, and published the results of his researches in the *Arch. f. Hygiene*, Bd. ii., Heft. 2, 1885. These investigations took place under the supervision of v. Pettenkofer. Air containing one-twentieth of one per cent. of the acid can no longer be inhaled without injury.

The effect becomes apparent mainly in the blood, sulphurous acid being a virulent blood-poison. The animals experimented upon did not die from want of O, but from the presence in the blood of a CO hæmaglobin, entirely foreign to the normal composition of the circulating fluid. Corpuscles whose O has been taken up by the SO_2, and which contain therefore SO_3, even in very minute quantities, act as poisonous agents.

In recent times disinfection of the atmosphere with sulphurous acid has been recommended in some epidemics. While unquestionably effectual, its application will have to be practiced with care, by reason of the facts above elucidated.

Notes and Comments

Cerebro-Spinal Fever.

The experience of physicians in our country seems to be in favor of opium as the main remedial agent in epidemic cerebro-spinal meningitis. To be effective it must be given as early as possible, by all means before the symptoms of plastic effusion appear, and in decided, even heroic doses. Still some cases will die. But Dr. Lange, of Stettin, published a peculiar treatment of his own in the *Allg. Med. Centr. Zeit.*, May 6, 1885. He tried this treatment during the epidemic of 1864, and again in 1884, and found it so uniformly successful, that he recommends it as a specific cure for this dangerous malady. The records of a considerable number of cases accompanies the report. Although Lange's article is the leading one in the celebrated German medical journal (one of the best, oldest and most reliable in Germany), and although the article makes at least partly the impression of the writer's sincerity, the uniformly favorable result in this grave disease causes us to doubt the correctness of the author's diagnosis in every case. We do not think that he intends to deceive us, but we have the suspicion that he has himself been deceived. And yet he may be right, and for this reason alone we publish in the following his method of treatment:

First, especially if the vomiting is intense, when the sod. bic. is increased in dose, L. administers:

℞.	Magnes. ust.,	ʒi–gr. lxxx.
	Cupri oxid. nigri. p.	gr. iiiss.
	Aquæ nicotian. destill.,	f. ℥j.
	Aquæ destillat.,	f. ℥v.

M. S.—First every hour, then every two hours, a tablespoonful.

Then:

℞.	Sod. bicarbonatis,	ʒijss.
	Tragac.,	gr. v.
	Aqua destill.,	f. ʒv.
	Aqua nicotian. destill.,	f. ʒj.
	Cupri oxid. nigr. p.,	gr. iiiss.

M. S.—Same as first. And:

℞.	Tinct. cupri acet.,	f. ʒss (♏xxx.)
	Aq. nicot. dest.,	f. ʒj.
	Aqua cinnamomi, mucil. gm. mim.,	āā f. ʒss.
	Aqua destil.,	f. ʒiv.

M. S.—A tablespoonful every two hours.

The first (magnesia) mixture is generally administered but once; as soon as its purgative action has been established, the bicarbonate of sodium mixture is substituted. (The fact mentioned alone causes us to doubt L.'s correct diagnosis, for in true cerebro-spinal fever the bowels are not thus easily moved.) "If constipation was not present," (?) continues the author, "then two bottles of the bicarbonate mixture are given, and with them the indication for the alkalines, which is never absent, is sufficiently fulfilled. Then the last mixture, containing tinct. cupri acet. is administered, and this is continued for some time after all symptoms have disappeared, as otherwise a relapse is apt to occur. (!?) How rapidly the doses should follow each other the severity of the case must determine."

Again, very peculiar are the concluding remarks of the author, Headnits, that he believes in the infectious nature of the disease. He also acknowledges that neither copper nor tobacco are germicides, but thinks, as in other cases, it has also been shown that the destruction of the germs is impracticable, that the fact of copper, etc., not having that effect would be proof of the correctness of his views. "For," he concludes, "it is only necessary to preserve to the affected organs their normal power of resistance, and the remedies mentioned evidently effect this desirable result."

How copper and tobacco can preserve the power of resistance, normally lodged in the brain, is more than we can comprehend.

In one of the cases reported by L. he did not see the patient until all the symptoms, which had been very mild in this case, had ceased, only the deafness remaining. "But," L. says, "convalescence set in, only the deafness did not improve, though I do not doubt that this also disappeared." As all the symptoms had already ceased when the case came under L.'s charge, convalescence must have been established ere L. saw the case; and how L. can suppose that the deafness left of its own account, without his having the slightest proof for it, is the more peculiar, as it is well known, whatever other sequelæ of this frightful disease might later yield to treatment, deafness is *the* one which never improves.

For some unexplained reason there may be some virtue in L.'s treatment, and considering the fatal character of the malady, it may be worth while to try L.'s method. But if he is as unreliable and shaky in his diagnosis as he is in his other statements, we do not promise ourselves any success with his treatment.

Syphilitic Infection.

A series of lectures on syphilis, by M. Leloir, of Lille, is appearing in the columns of the *Progrès Médical*. M. Leloir has collected a large number of cases where chancres have appeared in unusual situations, and in all these cases there was evidence both that the epidermis was denuded

from the site of the chancre at or before infection, and that syphilitic virus was deposited on the denuded spot. The natural arrangement by which the tissues of the vagina are capable of great distension without rupture, and considerable friction without laceration, account for the rarity of vaginal chancres. Anal chancres have been repeatedly observed in women who have subjected themselves freely to natural coitus when suffering from slight fissure of the anus, infected fluids running harmlessly over an unexcoriated vulva and perineum, to find a nidus in a fissure. The great frequency of fissure in the anus, in women with neglected gonorrhœa, is well known. M. Leloir described cases of infection through eczematous patches on different parts of the body. There is strong evidence that syphilitic virus has lain on an uninjured epithelial surface for some time without infecting the subject. On the other hand, there is still stronger evidence of a very serious fact, which proves that cleanliness alone will not always protect the profligate and the careless from syphilis. When syphilitic virus falls on a surface denuded of its epithelium, absorption is instantaneous, and resists the most rapid preventive measures. A surgeon, who had just grazed his finger, observed, in examining a syphilitic patient, that the excoriation touched, for a second, the surface of a chancre. He scrubbed the finger thoroughly with soap and water at once, but all in vain, for in a few weeks a chancre appeared on the finger, and was followed by constitutional syphilis of the severe type often seen in such cases. Several precisely similar cases have occurred amongst British practitioners. M. Leloir believes that early cauterization may destroy the virus, but states that this theory has not been thoroughly proven. He lays great stress on the fact that a hard sore undergoes a long period of incubation. "Never has a chancre, the first sign of a reaction of the organism against the syphilitic virus, shown itself on the first day, nor on the second, nor on the fourth, nor even during the first week." M. Leloir gives the twenty-fifth day as the medium date. By unjustifiably allaying the apprehensions of a patient too quickly, he may be induced, as has not unfrequently happened, to look upon a chancre that has appeared very long after infection as a mere excoriation, and, on the strength of his error, he may spread infection to others. M. Leloir has observed the "premonitory herpes" of Cusco, a crop of herpetic vesicles sometimes appearing on the prepuce two or three days before the chancre, and possibly due to irritation of the nerves of the skin by the virus. This complication may, obviously, be a source of fallacy in a patient who persists in excesses after actual syphilitic infection.

Pyridine.

From a foreign exchange we learn that M. Germain Sée, in a communication to the Academie des Sciences on pyridine, states that neither subcutaneous injections of pyridine salts, nor smoking cigarettes of pure pyridine, offered the same advantages in asthma as the practice of administering it by inhalation. Four or five grammes are poured onto a plate, which is placed in a closed room containing rather less than twenty-five cubic metres of air. The patient, in the room, breathes the air impregnated with pyridine. This treatment should be repeated, for about twenty minutes, three times a day. Pyridine can be traced in the urine almost immediately after the commencement of an inhalation. According to Dr. Germain Sée, hypodermic injection and pyridine cigarettes provoke nervous disturbance. Inhalation produces a beneficial effect; the feeling of oppression common among asthmatic patients being relieved, breathing becomes easier, and they have no longer the characteristic intense longing for fresh air. The sensibility of the pneumogastric nerve and the excitability of the medulla are considerably diminished, and the heart's action becomes normal. It frequently happens that the patients fall asleep after the inhalations. This sleep is almost normal, and is not accompanied by profound insensibility, and is, therefore, different from that provoked by anæsthetics. While it lasts, sensations, followed by reflex phenomena, are provoked with difficulty, although contractile energy is maintained. The administration of pyridine is not followed either by paralysis, convulsions, or tremors; but the muscles are relaxed, and temporarily lose their tonicity, in consequence of the lessened sensibility of the medulla oblongata and spinal cord. This modification of reflex sensibility is the special characteristic of pyridine, as distinguished from substances like nicotine and atropine. All the patients to whom Dr. Sée administered pyridine had quiet nights, though previously tormented with violent fits of coughing and intense oppression. The physical pulmonary symptoms all showed improvement. Pyridine does not affect the general health. When the suffocating asthmatic fits reappear after inhalations for nine or ten days, Dr. Sée recommends the administration of iodides. He has treated fourteen patients, nine of whom were asthmatic,

and five subject to cardiac disease; they were all relieved. One patient had suffered from asthma for twelve years; he was greatly relieved by the treatment with pyridine, but it was discontinued in consequence of troublesome attacks of vertigo and sickness. The asthmatic patients who presented cardiac and renal complications, declared that respiration was much eased by the inhalations. Dr. Sée concludes that pyridine is preferable to hypodermic injection of morphia, its action being preferable and less dangerous.

A Study of the Subject of Spontaneous Rupture of the Membranes at Full Term of Gestation Preceding the Beginning of Labor.

Dr. G. W. H. Kemper, of Muncie, Ind., in the April issue of *The American Journal of the Medical Sciences*, offers a careful study of fifty cases of spontaneous rupture of the membranes, occurring in his first 700 obstetrical cases, and he finds that—

1. The spontaneous rupture of the membranes at full term of gestation, and preceding the beginning of labor-pains, is an event of common occurrence, averaging about once in every fourteen labors.

2. When the membranes are broken, as a rule, labor supervenes at once, or within the next four hours, but may be delayed several hours, days, or even weeks.

3. When such an accident occurs, the duration of the labor is not necessarily prolonged, nor rendered more painful.

4. The mortality of the mothers is not augmented, and the ratio of still-born children, if at all, is so slightly increased as to amount to a minimum.

5. The causes are not well defined. The repetition of the accident in certain women shows that with some a tendency is inherent. A possibility of atmospheric influences, especially a low temperature, as an exciting cause, is admissible. Smellie considered obesity a cause. His observations have not confirmed this statement.

6. It is probable that the duration of labor is shorter in cases where the appearance of pains is delayed for some time after the membranes are ruptured.

7. The proper plan of treatment, as given by Smellie, McClintock, Bard, Denman, and Dewees, and corroborated by Dr. Kemper's experience, is rest, if necessary in a recumbent posture, and patience. All efforts to excite labor-pains are hurtful, meddlesome, and mischievous. Wait for pains, and treat the case on general principles!

8. Finally, that the fear of delay and danger in this class of cases—the classical "dry labor"—promulgated by our early obstetrical fathers, and indorsed by successive authors generally, is based on a merest spark of truth, and is one of those medical traditions that experience shows to be over-estimated and to a large degree apocryphal!

Conservative Ovariotomy.

From a foreign exchange we learn that Professor Schatz, of Rostock, has described in the *Centralblatt für Gynäkologie*, June 6th, a highly interesting case of pregnancy following double ovariotomy performed after a plan recently advocated by Schröder. On February 20, 1880, Dr. Schatz removed from a girl aged 20 a large cystic tumor of the left ovary, including the outer third of the Fallopian tube, and all the ovarian tissue. The right ovary was distinctly enlarged and cystic; it was ligatured by means of three silk threads passed between it and the broad ligament, and cut away in such a manner as to leave a piece of ovarian tissue, hardly two millimètres broad, on the proximal side of the ligature. The right tube remained intact. An abscess formed, during recovery, in the track of a suture in the abdominal wound. On March 21st, when the period was due, severe pain was felt on the right side of the hypogastrium and right thigh, with vomiting and fever. The symptoms recurred on April 8th and May 8th. No deposit could be detected in the pelvis. The first "show" appeared on May 9th; it lasted three days, and was pale and scanty. It recurred on May 31st. In the interval, there were attacks of pain in the left groin. On June 11th, a swelling of the size of a plum was detected behind and to the left of the uterus, which was strongly anteflexed. On June 28th, severe sacral pain set in; it radiated to the left inguinal region, and disappeared at period, which was copious, and lasted for six days. On July 15th, the uterus was found to be small and retroverted. The catamenia thenceforward appeared regularly till the patient's marriage in April, 1884. She became pregnant in September, and was delivered on May 12th of this year.

Case of Recovery from Malignant Pustule.

Dr. W. E. Buck thus writes in the *Brit. Med. Jour.*, July 4:

Mr. F., aged 31, a veterinary surgeon, experienced on October 6 a stinging sensation at the back of the right wrist. A small bleb was formed, which he scratched off, and there was some ten-

derness of the elbow and arm-pit. He had a slight rigor. On October 8, he was seen by Dr. Meadows, who prescribed some salicylate of soda and tincture of aconite, in frequent doses, as his temperature was 104°, and the rigors continued almost the whole of the day. A black eschar began to form on the afternoon of the 8th, and on the 9th it became about the size of a sixpence; its base was red and œdematous, and surrounded by some vesicles in a circular shape.

The temperature was nearly 104°; the patient felt cold, and his tongue was foul. I visited the case with Dr. Meadows, and we injected pure carbolic acid under the eschar, using an ordinary hypodermic syringe. Unfortunately we could only introduce a small quantity, as it oozed out in the withdrawal of the syringe, and with it a serous-looking fluid. I dried some of this fluid on a cover-glass, stained it with methyl-violet, and found the well-known bacilli of anthrax. We prescribed large and frequent doses of soda-hyposulphite, and ordered also a large quantity of meat. Under this treatment he rapidly improved.

On October 12, we again injected carbolic acid. The temperature came down, and, as the patient said he felt all right, the hyposulphite of soda was reduced to three times a day. The eschar did not finally separate for nearly six weeks, and the ulcer then soon healed. I believe that the main remedy in this case was the injection of pure carbolic acid, a mode of treatment which does not seem very painful.

There was a clear history of the disease, which was contracted exactly twelve days before its first appearance. Mr. F. having examined the flesh of an animal that had died from anthrax.

A Contribution to the Pathology of Malarial Fever.

Drs. W. T. Councilman and A. C. Abbott, of Baltiomre, report, in the April number of *The American Journal of Medical Sciences*, two cases of malarial coma, with post-mortem examination, of especial interest in connection with which was the presence of small hyaline masses in the brain and elsewhere. The authors fully consider the arguments pertaining to the supposition that these hyaline bodies are living organisms, without being able to arrive at any definite conclusion.

With a view of shedding some light on the subject of lower organisms in malaria, they made a careful search for the bacilli of Klebs and Tommasi-Crudeli, and for many other lower organisms, in all of the cases of malarial fever which came under their observation on the post-mortem table. In no case were any bacilli, bacteria, or micrococci found. Only in the two comatose cases, which they have fully described, were the singular hyaline bodies found.

This is an argument against the probability of these hyaline bodies being micro-organisms. They cannot suppose the comatose form of malarial poisoning to be a special disease, and were a lower organism found in this, it should also be found in other cases.

Digital Tenotomy in Pianists.

The operation devised by Dr. Forbes, of this city, Dr. Noble Smith, of London says, in the *Brit. Med. Jour.*, July 4, 1885, promises to be one of great benefit to accomplished pianists, as well as to learners. In making some dissections on the dead body, with a view to determine the usual position of the slips of tendon which limit the action of the extensor of the ring-finger, he found that these vary very much in different cases; so that it becomes necessary to carefully determine their position by the eye and finger, during movement of the extensor-tendon, in each case before operation. He has just succeeded in freeing the ring-finger of the right hand of an accomplished lady pianist, without causing her much more pain than is felt from the prick of a needle. Before operation, she was able to raise the finger only five-eighths of an inch beyond the others. Directly after operation, she could raise the finger easily to one and a half inches, without the least feeling of loss of control over its action. The division was, of course, made subcutaneously, so that only a minute wound was left in the skin, one-eighth of an inch in length.

Laryngeal Hemorrhage.

The name laryngeal hemorrhage is used for a variety of affections which differ widely in regard to cause, nature of the disease, and severity of the symptoms, and have in common only the effusion of blood into some part of the larynx.

Dr. J. W. Gleitsmann, of New York, in a paper in *The American Journal of the Medical Sciences* for April, proposes to designate by the name laryngitis hæmorrhagica, such effusions of blood on the free surface, or under the epithelium of the mucous membrane, which are of a so-called idiopathic character, and not due to any constitutional disease or traumatic origin. He records a case of this character, and analyzes those that have been heretofore recorded. He finds that in exceptional cases only is hemorrhage from the larynx a precursor of phthisis.

Report of a Case of Partial Pylorectomy.

Dr. J. M. Spear, of Cumberland, Md., reports, in the *American Journal of the Medical Sciences* for April, 1885, a case of partial pylorectomy in a blacksmith, aged 40, who suffered from cicatricial stenosis of the pylorus. The operation was a modification of Billroth's, and required one hour and a half for its performance. The tumor was not adherent. Death ensued in two and a half hours, from collapse. In the opinion of Dr. Spear the case was an eminently proper one for operation, but it should have been performed at an earlier period in its history.

CORRESPONDENCE.

A Case of Aconite Poisoning.

EDS. MED. AND SURG. REPORTER:—

I was called to treat a case of pneumonia in a robust adult male. I prescribed aconite to lower arterial action. The pulse was frequent and bounding, and forty-eight drops of Fleming's tincture of aconite root was left in a glass of water to be taken in twelve doses. The nurse, in mistake, gave this mixture for a glass of lemonade which she had just prepared. The mistake was immediately discovered, and I was called again within a few minutes after the ingestion of the poison. I at once resorted to all the available emetics at hand, and alternately gave mustard and tepid water and thirty-grain doses of ipecac. Vomiting and purging was produced in twenty-five minutes. The patient complained of giddiness and quivering of the muscles; also the characteristic tingling. The pulse was now imperceptible. The respirations shallow and frequent. I gave a hypodermic syringe full of brandy, which brought back a feeble, irregular pulse for a few minutes, and the drug showed its depressing effect more marked than ever. The skin was cold and sweaty; the countenance livid and anxious, while the purging and vomiting continued. I informed the family of the serious condition of the patient, and Dr. G. A. Parker, of Southampton, Pa., was called for consultation.

During this time I repeated the hypodermic injections of brandy every few minutes, which seemed to sustain the heart for a very few minutes only. Ammonia was added with good effect for awhile. The pulse would gain and sink lower and lower. Thirty minims tr. digitalis was added to the injections of ammonia and brandy, and repeated alternately at intervals of five to ten minutes. This last addition had also a happy effect. The systole of the heart was perceptibly strengthened, and the patient revived for a time under its use.

Notwithstanding all this, the poison still gained its power, and by the time that nine hours had elapsed, the patient seemed in a hopeless condition. A mustard plaster was placed over the cardiac region. Bottles of hot water, and flannels soaked in hot whiskey were placed about the cold extremities. No arterial pulsations could be felt in them, and we could not detect any heart sounds on auscultation over the chest. The patient was conscious, with contracted pupils and a livid, sunken countenance. The respirations were very frequent, but the voice and sensation were not lost. At this time twelve hours had passed from the ingestion of the drug. The purging and vomiting having now ceased the remaining half-pint of hot brandy was injected into the rectum, and the patient was left for an hour.

Dr. Parker returned to the room, and found a faint radial pulse. It seems that by this time the stimulants had gained sway over the poison, and with renewed efforts the patient was on the road to recovery, which was complete, and the man is now well.

O. C. ROBINSON, M. D.

Huntingdon Valley, Pa.

Blue Lick Water in Treatment of Lichen.

EDS. MED. AND SURG. REPORTER:—

Three years ago this summer I was consulted by a man about fifty years of age, a native of England, and who had been a resident of this country for not more than a couple of years. He declared himself as driven well nigh to desperation by the intolerable itching attendant upon his malady, which was plainly a most aggravated example of *Lichen Ruber*. The characteristic papular eruption covered the thorax, abdomen, genitalia, thighs, backs of hands, and face. None of the lotions, washes, etc., he had ever used had afforded much relief, and the same he stated to be true concerning internal remedies, of which he has taken great quantities. He further mentions a fact that at the time did not convey to my mind the valuable suggestion it contained, namely, that drinking of the waters of the Harrowgate Springs, of Yorkshire, was the only agency that had ever brought him any substantial relief. I should mention that the beginning of the symptoms dated back some four or five years, and occurred only during the warm season. All the points in the history of the case were not noted at the time, but I have same vague recollection of a history of rheumatism preceding the first attack of the eruptive disorder.

I prescribed alkaline treatment with arsenic; and locally, a carbolized ointment. The use of these was persisted in for some time, with no resultant benefit. One day, during the recital of a most unsatisfactory account of his condition and symptoms, he ardently expressed the wish that Harrowgate was accessible. The idea then occurred to me to look into the composition of this mineral water, in the hope of finding an American water of similar composition and properties. It required but little research to discover a marked similarity between the Harrowgate and the Blue Lick of Kentucky. They compare as follows:

Harrowgate.	*Blue Lick.*
Chloride of sodium.	Chloride of sodium.
Chloride of magnesium.	Chloride of magnesium.
Chloride of calcium.	Chloride of calcium.
Chloride of potassium.	Chloride of potassium.
Carbonic acid gas.	Sulphates.
Sulphuretted hydrogen.	Sulphuretted hydrogen.
Sulphohydric acid.	Iodides.
	Bromides.

It will be observed on comparison of the above, that they are essentially identical in composition, and the inference of their meeting the same therapeutic indications is a most rational one. At any rate, I prescribed Blue Lick water. The effect was prompt and gratifying. The eruption rapidly subsided, and the patient's condition was soon changed from that of great misery to comparative comfort. The circumstances of my patient were not such as to permit of his visiting the springs and partaking liberally of the water. For a time he purchased it in small quantities of the local druggist, but afterwards procured it by the barrel direct from the springs. This he does with the recurrence of the warm season, and is thereby enabled to live in some measure of enjoyment. The quantity he is using this season is half a gallon per day. This amount keeps the disease effectually under control. I see much reason to believe that a thorough and extended course of treatment at the springs would effect a thorough eradication of the ailment.

Of course, I have not concluded that this is the treatment for all cases of lichen. There are cases that prove very rebellious to this and all other plans of treatment. As a general principle, it may be stated that the most promising treatment of lichen ruber is the arsenical. Lichen planus calls for alkalies and tonics. The history of rheumatism in my patient may explain the action of the mineral water in lichen ruber. This is the fourth season he has used it. It is his sole dependence in the way of treatment, the effect never failing in promptness and efficacy.

JOHN J. THOMAS, M. D.

Youngstown, Ohio, July 28, 1885.

How to Take a Pill.

EDS. MED. AND SURG. REPORTER:—

Dr. H. Asthalter, in his note to you, "How to Take a Pill," tells of a very difficult way of linguaglutition, or deglutition. One cannot easily take a pill that way. Try it. In drinking, the tongue does not "curve back upon itself." Only after the liquid has passed the epiglottis is the tongue drawn back, curved by an involuntary nervous influence. Besides, you have the disagreeable taste of the pill—the thing patients complain most of. Tell this way of *my own*, that I have used for many years, and many will be happy among our children, who are the most difficult pill-eaters.

First, I tell the patient (and this is the important step) to take a large mouthful of water (I wonder what your correspondent means by "other liquid" in his note—something to disguise the taste?); throw his head back and swallow; this opens and clears the œsophagus from sticky, thick mucus. Then take another large mouthful of water, throw the head back—away back—drop the pills in, and swallow, and you have a straight road to the stomach, not a curved one.

I have never any trouble. I have heard of the "under the tongue" way. It is only a popular fallacy.

WILLIAM M. OGDEN, M. D.

520 *Shawmut Avenue, Boston, Mass.*

NEWS AND MISCELLANY.

Lehigh Valley Medical Association.

Fifth annual meeting of this Association will be held in the National Bank Hall, Quakertown, Pa., Wednesday, August 19, 1885. The profession is cordially invited to attend the sessions of the Association.

PROGRAMME.

MORNING SESSION—10:30 O'CLOCK.

1. Roll call. 2. Address of welcome, Joseph Thomas, M. D., President of the Association. 3. Appointment of a Nominating Committee. 4. New business (including report of Executive Committee, of the Treasurer, and election of members). 5. Unfinished business (including action upon proposed revision of constitution and by-laws). 6. 11:30—Special hour.

Address, "Proper Organization of Local Boards of Health," Benjamin Lee, M. D., Secretary State Board of Health.

Recess for dinner.

AFTERNOON SESSION—2:30 O'CLOCK.

1. Report of Nominating Committee. 2. Unfinished business. 3. 3 o'clock—Special hour. Address, "The Treatment of Joint Diseases by Rest," De Forrest Willard, M. D., Lecturer on Orthopædic Surgery, University of Pennsylvania. 4. Miscellaneous business. 5. Induction of President-elect. 6. Adjournment.

Following are the officers for 1885:

President—Dr. Joseph Thomas, Quakertown.

Vice Presidents—Dr. J. A. Horn, Mauch Chunk; Dr. J. D. Dewitt, Harmony, N. J.; Dr. C. J. Keim, Catasauqua; Dr. Amos Seip, Easton.

Secretary—Dr. Charles McIntire, Jr., 104 North Fourth street, Easton.

Corresponding Secretary—Dr. Isaac Ott, Easton.

Treasurer—Dr. Abraham Stout, Bethlehem.

Executive Committee—Dr. J. F. Wertz, Berks; Dr. A. M. Cooper, Bucks; Dr. J. B. Tweedle, Carbon; Dr. G. N. Best, Hunterdon; Dr. B. E. Stem, Lehigh; Dr. S. W. Trimmer, Luzerne; Dr. W. L. Estes, Northampton; Dr. P. F. Hulshizer, Warren.

Local Committee of Arrangements—Drs. Joseph Thomas, R. J. Lindermann, and J. S. Moyer.

NOTES.

Railroads.—The Philadelphia and Reading Railroad will issue special excursion tickets, at the rate of two cents a mile, on the 18th and 19th, good to return until August 21st. Orders for these tickets may be obtained of the Secretary.

The Lehigh Valley Railroad Company will have special excursion tickets (at same rate) for sale at Easton, Allentown, Catasauqua, Coplay, Lehighton, Mauch Chunk, White Haven, Weatherly, and Hazleton, on the 19th, for Bethlehem. Tickets from Bethlehem to Quakertown must be purchased of the P. & R. agent at Bethlehem, for which the special orders must be had of the Secretary.

Dinner.—Arrangements have been made to have the Annual Dinner served at the Bush House. It is especially requested that all who are planning to come would notify the Secretary of their intention by not later than the 15th. As the person so reporting is under no pecuniary obligations

should be be prevented from coming, and as an estimate of the number expected to dine will be a great help to the caterer, it is urged that every one who hopes to be present will comply with this request.

While there will be no excursion this year, the executive committee would be glad to see the innovation of last year continued, and that the members and guests bring lady friends with them.

The executive committee will be in session in the morning, and during the recess to act upon applications for membership. Blank applications can be obtained of the Secretary.

Every one, visitors as well as members, is requested to register on arrival in the morning.

Members-elect will please also sign the constitution.

It will be a great convenience to the Secretary if the members will pay their annual fee upon registering.

DEPARTURE OF AFTERNOON TRAINS.

For Philadelphia—1:02, 3:10, 4:50, 7:26, 9:14.

For Bethlehem—3:27, 3:54, 5:35, 7:08, 9.19.

For Mauch Chunk—L. & S., 3:27, 3:54, 7:08; L. V. R. R., 3:27, 5:35, 9:19.

For Allentown, L. V. R. R.—3:27, 3:54, 7:08, 9:19.

For Reading—3:27, 7:08.

For Easton—3:27, 3:54, 5:35, 7:08, 9:19.

For Belvidere, N. J., L. & S.—3:27, 7:08. L. V. R. R., 3:54, 7:08.

For Lambertville, N. J., L. & S., or L. V. R. R.—5:38.

For Washington, N. J., L V. R. R.—3:54.

The Health of Nomadic Populations.

The *Brit. Med. Jour.* (July 4th) tells us that the Association of Sanitary Inspectors were recently gratified with a paper, in Dr. B. W. Richardson's best manner, on a subject which, lying outside the ordinary pale of sanitary criticism, possesses greater attractions for both the lecturer and his audience. The sanitary condition and inspection of our homeless and nomadic populations are important questions, and the more important because it is no one's special business to look after them. Vagrants constitute one of the gravest difficulties, not only in the work of the poor-law, but also in that of the public health. These difficulties were not, however, the special concern of the lecturer, who defined the object of his inquiry as "to trace how far modifications of life among the homeless created varieties and extensions of disease amongst the rest of the community." There were (1) the pure vagrant, who wandered about without any provision which could be called a home, trusting to the casual ward, or any temporary shelter; (2) those who carried on an itinerant trade, and possessed a van, in which they lived and slept; and (3) the pure nomadic class, gypsies, who lived in tents, and slept on the ground in sheltered nooks, or under the brushwood of commons and moors. As to the vagrant classes, his opinion was that, while they were very helpless, by nature indolent, and by position placed in the most precarious conditions, there really was not much acute disease among them. They lived a comparatively short life, and became prematurely old, but they were rather exempt than otherwise from many of the diseases which resulted from luxury or comfort. Zymotic diseases were rare in this class, and diseases like consumption were also rare. A very important question was the influence which these people exercised in spreading contagious diseases. At first sight, it might appear that they were the best of agents for disseminating contagion. They traveled from place to place, they were not cleanly in their habits, they often wore garments which had been thrown away by infected persons, and they became the occupants of common lodging-houses, where many people were herded together. For all this, according to his observations, they did not seem to be disseminators of disease. This is certainly opposed to general experience, and we fancy a good many medical officers of health will be inclined to traverse the accuracy of Dr. Richardson's decisions.

Amongst the itinerant hucksters, however, Dr. Richardson admitted that epidemic diseases were by no means uncommon. Their children were often scrofulous, unhealthy, and feeble, while their adults were subject to consumption. These people were also subject to other constitutional diseases, particularly those affecting the chest, asthma, bronchitis, and the various forms of disease of the heart. They—perhaps, too, more than the vagrant classes—suffered from the effects of intemperance. As to the third class—the nomadic or gipsy class—the lecturer said that he could speak from considerable experience of their manners, habits, and diseases. Gypsies were constitutionally a very healthy race; and, as far as observation upon them went, they were more distinctly free from the fatal diseases of the community than any other class, so long as they retained their original nomadic mode of life. When they began to mix and live with the people generally, they suffered like other people, although even then their diseases were rather special in character. In their out-door life—living in tents—they suffered from rheumatism, which was their most common enemy, but they were extraordinarily free from the other affections. He had never heard of an epidemic of small-pox among gypsies, nor seen one of them who was pitted with small-pox, although he believed they were very indifferently vaccinated. The gipsies were not intemperate, and many of them attained to considerable longevity. From these observations the lesson adduced was that, as soon as men began to aggregate in close localities, without due and proper sanitation, and with the means of obtaining "creature comforts" too much at command, they contrasted indifferently in regard to health with their apparently less fortunate brethren, who were content to confront nature in her wildest moods. No doubt over-crowding and the aggregation of great multitudes of people in towns lies at the root of many, if not most, of the maladies which make life less endurable; and the nearer we approach to pastoral simplicity of life and surroundings, the healthier we shall be. But, human nature being what it is, we fear that not even Dr. Richardson's attractive picture will tempt the majority of people to exchange their lot for that of the vagrant or the gipsy.

Adaptation of the Dietary.

We are thus led to the next important consideration, namely, that although broad rules or principles of diet may be enunciated as applicable to different classes of people in general, no accurate adaptation to the individual is possible without a knowledge of his daily habits and life, as well as to some extent of his personal peculiarities. No man, for example, can tell another what he can or ought to eat, without knowing what are the habits of life and work—mental and bodily—of the person to be advised. Notwithstanding which, no kind of counsel is more frequently tendered in common conversation by one stranger with another, than that which concerns the choice of food and drink. The adviser feels himself warranted, by the experience that some particular combination of nourishment suits his own stomach, to infer without hesitation that this dish will be therefore acceptable to the stomachs of all his neighbors. Surely the intelligence of such a man is as slender as his audacity and presumption are large. It would not be more preposterous if, having with infinite pains obtained a last representing precisely the size and the peculiarities in form of his own foot, he forthwith solemnly adjured all other persons to adopt boots made upon that model, and on none other! Only it may be assumed that there is probably more difference between stomachs, and their needs among different individuals, than among the inferior extremities referred to for the purpose of illustration. Thus, in regard of expenditure of food, how great is the difference between that of a man who spends ten or twelve hours of the day at the work of a navvy, as an agricultural laborer in harvest time, or in draining or trenching land, as a sawyer, a railway porter, or a bricklayer's laborer, or let me add that of an ardent sportsman, as compared with the expenditure of a clerk who is seated at the desk, of individuals engaged in literary and artistic pursuits, demanding a life mostly sedentary and spent indoors, with no exercise but that which such persons voluntarily take as a homage to hygienic duty, and for a short period borrowed at some cost from engagements which claim most of their time and nearly all their energies!—Sir Henry Thompson, *in Popular Science Monthly for August.*

An Heroic Cure for the Opium-Habit.

A pathetic story has lately come to my knowledge of a young man, an under-graduate in an Eastern college, who had become a victim of the hypodermic use of morphia. He went with his father, who was engaged in the lumbering interest, into the primeval forests of Maine, hoping that during a stay of months with the wood-choppers he would be able to fight out the battle of gradual abandonment successfully. Through a strange fatality, when the party had just arrived at their camping-place, and were transporting their goods across a stream, the case of morphia was broken by an apparent accident, and its contents scattered into the water. None but the haggard young man could, at the moment, comprehend the appalling magnitude of the calamity —there, as he was, two hundred miles from the nearest settlement! He survived the terrible ordeal, but no words could express, he has said, the tortures and agony through which he passed during the succeeding weeks. He was closely watched, else, at times, he would have drowned himself or have beaten his brains out upon the rocks. Months afterward he came back to the world a skeleton, worn and haggard, from his terrible contest. It was an experience to which he could never afterward refer without the most painful emotions.

Not the least significant point in this veritable account, is the fact that the young man always believed that his father had purposely brought about the catastrophe for the sake of bringing matters to a speedy end! Has the usual treatment of the disease by physicians at this day anything to offer that is much better than this man's summary method?—*From "An Experience with Opium," by* S. T. Morton, *in Popular Science Monthly for July.*

Methods of Hanging.

The mode of carrying out the sentence of the law, "be hanged by the neck until you are dead," has usually been left to the discretion of the hangman, the law taking no cognizance as to what is to be the proximate cause of death. Calcraft invariably adopted the short drop of about two feet and a half; and if I may judge from some specimens of his ropes, which are still to be seen at Kirkdale, death must have been produced by a slow process of asphyxia. Marwood adopted what is generally known as the long drop, of which he was supposed by many to be the originator, though it was used before his time, both in Paris and in Ireland.

To Professor Haughton we are indebted for a scientific exposition of the *rationale* of the long drop, and the mode in which death takes place. Dr. Haughton also gives an elaborate explanation of the American method, which is a scientific modification of the old naval method of running the culprit up to the yard-arm.

Having now briefly referred to the different modes of hanging which have been adopted in executing criminals, we will be better able to judge which is the best and most practical method when we have considered the various causes of death. Professor Tidy says that "in hanging as in drowning, death does not always take place in exactly the same way. Thus, it may result from: (1) asphyxia; (2) cerebral hyperæmia; (3) a combination of asphyxia with apoplexy; (4) syncope; (5) injury to the spinal cord and pneumogastrics (neuro-paralytic death)."—*From "The Mechanics of Hanging," by Dr. James Barr, in Popular Science Monthly for August.*

Oophorectomy Run Wild.

The *Canada Med. and Surg. Jour.* says that Dr. Furber, writing from Kansas to the *Eastern Medical Journal*, says that the surgical mania of his State is spaying of women and young virgins. He says in his waking hours he often dreams of a courting scene in which the conversation runs thus: "Miss Doolittle, have you been spayed?" "Sir?" "Have you undergone ovariotomy?" "Please explain yourself, Mr. Blunt." "I desire to be informed, Miss Doolittle, whether or not

you have been oöphorectomized." "Certainly I have, Mr. Blunt. A council of regular physicians was called by my parents when I was a child, to consider the nervousness exhibited by my three elder sisters and myself, and thus oöphorectomy was performed on all four of us, by that eminent surgeon, Prof. Cassius Fitz Greene Browne, A. M., M. D. My older sisters all died, because they were not operated on earlier in life. So the doctors said, and they all agreed that where parents neglect to have their girl babies oöphorectomized, it ought to be done by the city surgeon appointed for that purpose, to prevent the thousand and one diseases that assail girls when they grow up to womanhood as their Creator made them; and they further say it should no more be neglected than vaccination, and certainly my own case proves the truth of their assertion." "I will thank you for my hat, Miss Doolittle. Good night." "Good night, Mr. Blunt."

Wells and Bacteria.

In *Science*, July 10th, we read as follows: In many towns and cities the privy-vaults and leaching cesspools of every house drain really into the sheet of ground-water. The soil arrests the coarse material, the grease and slime; but the swarming bacteria diffuse with ease, as much as the soluble chlorides and nitrates, and follow the flow wholly unobstructed. Into this same soil are sunk or driven the wells; and the water that is drawn for use is polluted in proportion to the number and proximity of the vaults and cesspools, on the one hand, and the thinness and sluggishness of the water-sheet on the other. In the worst wells in daily use the water is distinctly colored with sewage; but the most deadly water may carry only the germs of typhoid fevor or of dysentery, and be otherwise sparkingly clear, and so pure as to pass unchallenged through the most searching chemical analysis.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended August 1, 1885.

Fessenden, C. S. D., surgeon. Leave extended ten days on account of sickness, July 27, 1885.

Godfrey, John, surgeon. Granted leave of absence for thirty days, July 29, 1885.

Irwin, Fairfax, passed assistant surgeon. To proceed to Richmond, Va., and Wilmington, N. C., as inspector, July 28, 1885.

Ames, R. P. M., passed assistant surgeon. Granted leave of absence for thirty days, July 27, 1885.

Illinois State Board of Health.

The Illinois State Board of Health is now engaged in revising the "Official Register of Physicians and Midwives."

Any notification of changes, omissions, or errors will be regarded as a favor, as the Board wishes to make the coming register as correct as possible.

Address, "Secretary State Board of Health, Springfield, Illinois."

Items.

—Last year the number of medical and pharmaceutical students who completed their curriculum at the Universities of Spain was 703, the total number of students graduating being 3,598.

—It is recorded in the Bombay Season Reports, that on the 27th of last December, seven shepherds lost their lives at Athni, in the Belgaum district, through being struck by hailstones of the size of a cocoanut.

—M. Crouzel has isolated a body having all the properties of an alkaloid from the mandrake (Mandragora officinalis). This body forms a sulphate which is crystalline. A solution of this salt was found to have marked mydriatic effects on the eye of a rabbit. (*L' Union Pharm.*, p. 264.)

—A correspondent of the *Monthly Magazine of Pharmacy*, writing from Messina, says: "A bottle of bromine left in a closed room all night with the stopper out destroys all infection and insect life. I have cleared places which were infected with vermin many times. It is far more effectual than the vapor of burning sulphur."

—Dr. Peckholt, of Rio Janeiro, finds that the pulp of the cimmaroma, a plant found both in the Brazils and in Spain, is valuable as a laxative, ten grains of the alcoholic extract being sufficient to produce an action of the bowels. Mixed with vinegar and water, it is used by the natives of Brazil for erysipelas.

—Dr. Austin Flint, jr., adds four more cases of diabetes to the fifty-two reported to the American Medical Association. The patients were placed on strict anti-diabetic diet, and Clemens' solution of arsenite of bromine, beginning with three drops, increased to five, was also given. Of these four cases, three were permanently relieved. In conclusion, he adds: "Diabetes has become today a disease easily and certainly curable, provided that the treatment be not begun too late."

—The very rapid death of a boy, aged 15 years, from the inhalation of sulphuretted hydrogen gas in its pure state, is reported from Irvine (Scotland.) He was engaged in a chemical laboratory there, and was assisting in carrying out some experiments. In the absence of the person in charge, he approached a boiler which he had been cautioned not to go near, because of the presence of this gas, and immediately he fell down insensible. Though he was at once removed to the pure air, and every effort was made, under medical supervision, to restore animation, he never recovered consciousness, and died in an hour.

QUERIES AND REPLIES.

MESSRS. EDITORS:—

My attention has been called, and opinion asked, as to the "Brinkerhoff treatment of piles, rectal ulcers," etc., by a party suffering with same. I know nothing of it. What is it? Is there anything in it? A SUBSCRIBER.

DEATH.

GIFFORD.—June 14, 1885, at Laurel, Ind., of paralysis, in the 70th year of his age, Dr. Thomas Gifford, a member of the Franklin County and State Medical Societies, of Indiana.

THE

MEDICAL AND SURGICAL REPORTER.

No. 1486.] PHILADELPHIA, AUGUST 22, 1885. [Vol. LIII.—No. 8.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

AN EPIDEMIC OF ACUTE DYSENTERY.

BY JOHN A. STAMPS, M. D.,

Of Wallaceburg, Arkansas.

There is a diarrhœal trouble very prevalent in this vicinity which has given the medical man no little trouble in finding a course of treatment most satisfactory to himself and patient. It began in the latter part of June, and has continued more or less severely ever since. It is an acute inflammation of the mucous membrane of the intestinal canal, of a catarrhal nature, self-limited, the average duration of which is about ten days (though some cases last as long as three weeks), characterized by very slight and, in most cases, no fever. In the majority of cases there is tenesmus and tormina, with frequent mucous and bloody stools.

The exact cause of this malady is rather hard to get at. That it is due in part to excessive or imprudent dietary measures, such as indigestible food, or food taken in too great quantities, unripe fruits, etc., cannot well be denied, for some of the most intractable cases occur among patients of this class. There are cases, however, that had taken all dietary precautions, and had always been strictly temperate in every respect, and to show that diet had a controlling influence in the disease, these cases were the most amenable to treatment. Besides these causes, there has been an abundant rainfall in this country at short intervals during the spring and summer months, which has caused all living vegetable matter to flourish in a most prolific manner, and with increased growth there has been an increase in the amount of dead vegetable matter, and this, with all dead animal matter that may have existed near the surface, has been thoroughly saturated with water. This combined with the very hot weather that we have had for the past few months, has been sufficient to produce the so-called malarial poison.

The requisites given by Dr. T. S. Bell, formerly Professor of Hygiene in the University of Louisville, now dead, and a man of whose extraordinary talent there was no doubt, as all who have ever taken issue with him well know, was "a daily mean of temperature of 60° for sixty days, with moisture and decaying vegetable matter, opposing the views of some, *i. e.*, that decaying animal matter also produced the poison," as set forth in his lecture of October 20, 1884, and giving as a proof of his views the scourge of fever at Paris several years ago (not stating the date), in which the inhabitants attributed the cause to the germs of disease being blown from the place where all of the animals that died in the city were removed to, whereupon an inspecting officer was sent to the place to ferret out the cause, and to his surprise, found the most perfect types of health living among the carcasses, and further researches located the trouble under the Hotel Dieu. But be this as it may, the existence of such a poison in certain localities (and this is one of the places the subject of its ravages) is indisputable from the various methods by which it makes itself known, from an ordinary attack of brow-ache to the most virulent forms of pernicious fever.

And while we are aware of the fact that this many-headed monster, so to speak, has almost as

many ways of attacking the human system as there are monsters of the sea, yet to say that this is a true type of the poison would be to ignore the assertions of quite a number of the most eminent medical men of the age; for instead of being controlled by any of the salts of Peruvian bark, it seems rather to be made worse in the incipiency.

Still I am of the opinion that this disease is caused by an entity, *i. e.*, a something which while existing in the atmosphere is inhaled by all; it finds in some a constitution sufficiently vigorous to withstand its morbid effects, while in others it finds, as my very dear friend and noble teacher, Prof. Lunsford P. Yandell, jr., of Louisville, Ky., used to say in his lectures, "a soil suitable for its sustenance and growth," there develops in sufficient quantity, or if due to micro-organisms or germs, sufficient number, with, in many of the cases, the additional irritation of inordinate or indigestible diet, to produce the much-dreaded disease.

The following is extracted from J. Lewis Smith's most excellent work on diseases of children, page 693, as being well suited to this occasion, viz.: "We know that the air is a medium of communication of most of the infectious maladies, though the agents by which these maladies are produced are so subtle that they have for the most part escaped detection. We also know that when our senses can detect nothing wrong the air frequently contains principles which produce the most violent and fatal diseases; and that the impurities in the air arising from animal exhalations and excretions, and from decaying organic matter, are common and potent causes of diarrhœal maladies, is well established."

Since the microscope has been introduced into medicine, with all its modern improvements, as a diagnostic aid, there have been some very important announcements made regarding the etiology of many of the diseases which had for the past ages been a mystery to the medical man; and from the knowledge gained by this important diagnostic aid, we have been enabled to more successfully combat many of the diseases we meet, an instance of which is seen in many of the skin affections which were found to be produced by a parasite.

We can always tell pretty well by this means whether there will be benefit derived from the removal of a tumor, by finding whether it is a malignant or benign growth; while in those of a more grave and incurable character we have been led to adopt prophylactic measures to prevent the spread of the disease.

Since Dr. Robert Koch has immortalized his name by making known the results of his researches and experiments with the sputa of tuberculous patients, by which the disease is traceable to a specific micro-organism—the tubercle bacillus—Dr. W. H. Webb (in the April 25th and May 2d Nos. of this journal), in a most excellent article on the "Contagiousness of Tuberculosis," has, by means of carefully constructed germ traps through which the air might freely pass, leaving any existing impurities on veils of pyroxylin placed in the cylinders through which the air passed, demonstrated the presence of the tubercle bacillus on four of six slides prepared and examined by Dr. Morris Longstreth, of Philadelphia.

Now, with these facts before us, how can we reasonably doubt the supposition that the air is a medium through which many of the poisons are wafted, that when taken into a system somewhat below par, set up a train of morbid changes which result in the production of the disease peculiar to the changes or poison. Yet there has never been a time in the history of medicine when there were not critics ready to ridicule the researches and experiments of others; for instance, the very important discovery of the circulation by Harvey (in 1628), was scoffed at by most of the learned men of that age, and it was with the greatest difficulty that he succeeded in establishing the validity of his discovery, which was still incomplete, and he had scarcely had time to forget his persecutions, when Malpighi (in 1661), by means of a very insignificant magnifying glass compared with the instruments of to-day, completed the deficiency in Harvey's discovery by explaining the means by which the blood passed from the arteries to the veins, and Harvey was one of his most bitter persecutors.

Hence, we should profit by the lessons of the past, and receive the statements of others with that degree of zealousness that will buoy us up to search closely for ourselves, and not, through any envy we may cherish against those who have by being more diligent than ourselves brought out hidden mysteries, renounce their statements without having thoroughly investigated the matter. I hope that no one will for a moment entertain the idea that I consider the disease of which I speak contagious from man to man, for, on the contrary, I think it is a purely non-contagious disease, produced by a peculiar poison that is produced and propagated something after the order of malarial poison, if not in some way related to it, which, entering a system unable to withstand its morbid principles, develops the disease in pro-

portion to the condition of the patient's system, and the amount taken in. The symptoms begin with languor and chilliness, followed in a few of the cases by a slight elevation of temperature, which soon returns to normal, and remains so during the remainder of the attack.

Diarrhœa sets in more or less severely, with pain and slight tenderness on pressure over the transverse and descending colon, radiating pains about the umbilicus, an irresistible desire to go to stool, with tenesmus, tormina, and burning pain in the rectum; the stools at first consisting of rather thin fæcal matter, with a curdy material resembling partly-digested casein. Later on, mucus, blood and a substance looking very much like mashed vegetables make their appearance, and from this time on till there is an improvement in the case, the stools consist almost wholly of these last three elements. There are as many as four to six evacuations an hour, and in severe cases continuing this way from two to four days. There is complete anorexia, and this with the want of assimilation and excessive drain on the system produce extreme weakness and emaciation, which is most marked in the very young.

The tongue in the incipiency is moist, the centre being covered with a white fur, while the edges are free from coating, red, and the papillæ enlarged and hyperæmic. Later on the tongue becomes dry, the coating somewhat heavier, of a darker color, and in two of the three fatal cases that I have had from the disease it assumed a black hue. The pulse is increased in frequency and lessened in force, these conditions being marked in proportion to the gravity of the attack, in my three fatal cases it having reached 130 per minute and scarcely perceptible at the wrist for several hours before the fatal issue. The skin is dry, and has a peculiar leathery feel. The abdominal walls are flaccid and somewhat retracted. The kidneys act rather sluggishly, and in some cases fail altogether. The urine is scanty and high colored.

They have an insatiable thirst, and if water be allowed in large draughts it only aggravates the trouble.

The average duration of an attack may be put down at about ten days, some cases getting well in five or six days, others continuing more or less severely for as much as three weeks.

Convalescence in all cases is very slow, the patient being much emaciated and enfeebled from the excessive drain on his system, and the bowels remaining very irritable, the most trivial causes bringing on a diarrhœal trouble, while the bowels are already acting two to four times a day.

The most frequent complication is of cerebral origin, and as I have had no opportunity of holding a post-mortem, I cannot say what the lesions are, and perhaps the notes of a case would not be out of place. It was a little girl, æt. 3 years; the first indications of a cerebral involvement being a stupid sleepy condition, and when she moved she invariably went backwards, her decubitus being abdominal. Under treatment there was marked improvement for a day and a half, at which time the parents thought she was out of danger, as she was able to eat a light dinner, and talked with good reason; but, alas! in less than four hours she sank again, her decubitus being dorsal. She tossed her head from one side of the pillow to the other, was stupid, and when aroused would complain of pain in her head and ear, and pick at her ear and tongue, and would gradually doze off, muttering all the while. Temperature normal at first, but gradually subsided to subnormal. Pulse 130 and very feeble. Respiration somewhat labored, and when any of her attendants changed the position of her limbs, she would immediately move them again, with an air that indicated a desire to be let alone. In spite of all that could be done, the case terminated fatally.

In the treatment of these cases I have tried the various methods recommended by the books, as the ipecac treatment, the opium, ipecac, and camphor combined, and various others, and find the most satisfactory results obtained from the following course, to wit: I first give the following:

℞.	Hydrarg. chlor. mite,	gr. xij.
	Pulv. Doveri,	ʒss.
	Camphoræ,	gr. xij.

M.—Div. chart. No. xij. Sig.—One chart. every two hours, till a healthy action is produced.

This relieving the bowels of any fœcal matter which may have accumulated above the seat of trouble, the secretory function of the liver is stimulated to an increased action (and in all of the cases that I have seen this function has been more or less sluggish), and by bringing about this increased action relieves the portal congestion.

The opium and camphor relieve inordinate muscular contraction, quiet undue nervous excitability, lessen the purging effects of the calomel, and have a tendency to put the inflamed structures in splints, so to speak.

As quick as the stools have assumed a more normal character, I order 20-grain doses of bismuth subnit., after each action, no matter how often, this acting as a sedative, feeble astringent,

and soothing the inflamed tract over which it passes. I also order an enema, which I consider very important in all of these cases, especially when there is much pain and tenesmus, the following prescription rendering, in my experience, the most satisfactory results, to wit:

℞. Argenti nitras, gr. v.
Tr. opii, gtt. xl.
Bismuth subnit., ℥ss.
Mucil. acaciæ, and aquæ, āā ℥ij.
M. Sig.—Inject ¼ at a time every three or four hours after an action, retaining five minutes by means of a napkin.

This, acting as a local astringent and anodyne, proves very grateful to the patient.

If, after having tried this plan of treatment, the symptoms continue unmitigated, I order in addition the following mixture:

℞. Pulv. kino co., ℥ij.
Tr. opii, tr. camphoræ, chloroformi, spts. ammoniæ arom., āā ℥iss.
Spts. vini rec., q. s. ad. ℥ij.
M. Sig.—A teaspoonful in water every two hours.

This preparation, possessing astringent, stimulant, and carminative properties combined, usually affords speedy relief.

I failed to say before that as the tendency of the disease is to exhaustion from the excessive waste, I order vinous spirits of some kind, preferably blackberry cordial or wine, with the age on it, on account of its asserted astringent properties.

As to dietary, when they crave any food I allow them to drink rice-water, eat rice, well mashed, to which has been added milk boiled for a very few minutes only, as I believe it is injured by long boiling, and sugar, with such other flavoring as they may desire; or preferable to this, the whites of from four to eight eggs, well beaten, to which one-half pint of water, sugar, and other flavoring to suit the taste have been added—this not only acting as a nutritious food, but also forming an albuminous coating over the bowels. I find that quinine, instead of being beneficial in the earlier stages of the disease, rather acts as an irritant, aggravating the trouble; while later on, when convalescence has set in, it, with some preparation of iron, seems markedly to hasten the reparative process. Yet it matters not what treatment is adopted, convalescence is very tedious, and the least amount of imprudence causes a return of the diarrhœa, which has been troubling the patient to some extent for one or more weeks; yet this return is more amenable to treatment than the first attack.

PRACTICAL DISINFECTION.

BY VICTOR C. VAUGHAN, M. D., PH. D.,
Professor of Physiological Chemistry, and Associate Professor of Materia Medica and Therapeutics in the University of Michigan.

At the last meeting of the American Public Health Association, held in St. Louis, in October, 1884, the Association appointed a committee to investigate disinfectants and the modes of disinfection. The eminent bacteriologist, Dr. Sternberg, of the United States Army, was made chairman of this committee, and he has devoted several months of laboratory study to this work. At the request of the Sanitary Council of the Mississippi Valley, this committee has made a preliminary report, in which the following standard disinfecting solutions are recommended:

Standard Solution No. 1.

Dissolve chloride of lime of the best quality in soft water, in the proportion of four ounces to the gallon.

"The test of good chloride of lime is that it should contain at least 25 per cent. of available chlorine. The following directions are given for the use of this solution: "Use one pint of this solution for the disinfection of each discharge in cholera, typhoid fever, etc., mix well and leave in vessel for at least ten minutes before throwing into privy-vault or water-closet. The same directions apply for the disinfection of vomited matters. Infected sputum should be discharged directly into a cup half full of the solution."

Standard Solution No. 2.

Dissolve corrosive sublimate and permanganate of potash in soft water, in the proportion of two drachms of each salt to the gallon.

"This is to be used for the same purposes and in the same way as standard solution No. 1. It is equally effective, but it is necessary to leave it for a longer time in contact with the material to be disinfected—at least an hour. The only advantage which this solution has over the chloride of lime solution consists in the fact that it is odorless, while the odor of the chlorine in the sick room is considered by some persons objectionable. The cost is about the same. It must be remembered that this solution is highly poisonous. It is proper, also, to call attention to the fact that it will injure lead pipes if passed through them in considerable quantities."

Standard Solution No. 3.

To one part of Labarraque's solution (liquor sodæ chlorinatæ) add five parts of soft water.

"This solution is more expensive than the solution of chloride of lime, and has no special ad-

vantages for the purposes mentioned. It may, however, be used in the same manner as recommended for standard solution No. 1."

STANDARD SOLUTION No. 4.

Dissolve corrosive sublimate in water in the proportion of four ounces to the gallon, and add one drachm of permanganate of potash to give color to the solution.

"One fluid ounce of this standard solution to the gallon of water will make a suitable solution for the disinfection of clothing."

Besides the above solutions, the report contains a formula for a disinfecting and antiseptic powder, which is as follows: "One pound of chloride of lime; one ounce of corrosive sublimate; nine pounds of plaster-of-Paris. Pulverize the corrosive sublimate and mix thoroughly with the plaster-of-Paris. Then add the chloride of lime and mix well. Pack in pasteboard boxes or in wooden casks. Keep dry."

This formula has been objected to on the ground that the yellow oxide of mercury would be formed, and this, on account of its insolubility, would not be as effective as mercuric chloride. But this objection is valueless, because organic matter is capable of dissolving the yellow oxide, as may be proven by either of the following simple experiments: To an aqueous solution of egg albumen add some mercuric oxide, agitate and filter. To the colorless filtrate, add hydrochloric acid and chlorate of potash, and heat until all the organic matter is destroyed and all the free chlorine is driven off. Then treat the fluid with a current of hydrogen sulphide gas, when mercuric sulphide will be formed, showing that the mercuric oxide has been dissolved in the albumen. It is probable that the great value of yellow wash in syphilitic sores is due to the fact that the tissues dissolve and absorb the mercury. The second experiment may be made by the addition of egg albumen to yellow wash and the oxidation of the organic matter, as given above.

Messrs. Parke, Davis & Co., of Detroit, Mich., prepare all the above preparations, which I have examined chemically and found to be exact.

DISINFECTION OF THE PERSON.

The hands of the physician or attendants, or circumscribed portions of the body of the patient, when soiled with infectious material, may be washed with a solution made by adding five parts of soft water to one of Labarraque's solution. This is standard solution No. 3 of the committee, as given above. When the hands of the surgeon are soiled with highly infectious matter and the skin is unbroken, they may be washed in a solution of mercuric chloride (corrosive sublimate), one part to one thousand of water. This solution is, however, too poisonous for general use, and should not be employed by any one when there is any considerable abrasion of the skin. It is needless to say that it should not be applied to mucous membranes. When it is desirable to disinfect the entire surface of the body, one part of Labarraque's solution diluted with twenty parts of soft water is recommended by the committee. In case of death from infectious disease, the body should be thoroughly washed with a solution of mercuric chloride, of two drachms to the gallon of water. This, colored by the addition of two drachms of potassium permanganate, is standard solution No. 2 of the committee. The dead body should also be enveloped in a sheet saturated with this solution. Instead of the mercuric chloride, either standard solution No. 1 or No. 3 may be used.

DISINFECTION OF WEARING APPAREL.

Outer garments, when of value, should first be hung in a closet or small room, with the pockets turned inside out, then disinfected with sulphurous acid gas after the manner to be described in speaking of the disinfection of the sick-room; then they should be placed out-of-doors, and freely exposed to the air for twelve hours or more. Outer garments which are filthy, and also probably infected, should be burned; because, with such a suitable field for their development, the germs might not be destroyed by exposure to the vapor of burning sulphur. The best way of disinfecting the under-clothing is by boiling, as all germs are destroyed after being boiled for half an hour or longer. When boiling is not practicable, such clothing may be immersed for two hours or longer in a dilute solution of mercuric chloride, such as standard solution No. 4, diluted with water in the proportion of one fluid ounce of the solution to a gallon of water, or by immersion in a dilute solution of chlorinated lime, such as standard solution No. 1, diluted with nine parts of water. Messrs. Parke, Davis & Co. prepare standard solution No. 4 colored with bluing instead of potassium permanganate, especially for the disinfection of clothing.

DISINFECTION OF BED-CLOTHING.

The lighter articles of bed-clothing, such as thin blankets, sheets, pillow-cases, etc., may be disinfected as given above for under-clothing. Heavy articles may be spread out upon chairs, and freely exposed to the vapor of burning sulphur, and then freely exposed to the out-door air for

twelve hours or longer. Such clothing may also be disinfected by being spread out in a chamber especially constructed for the purpose, and exposed to dry heat of 230° F. or higher. The contents of the mattress should always be burned, as it is not safe to trust to either sulphurous acid gas or dry heat to sufficiently penetrate such material as to destroy any germs or spores that may have found lodgment.

DISINFECTION OF THE DISCHARGES.

Directions for the disinfection of discharges have already been given under the formulæ for the standard solutions. Rags which are used for the reception of sputa should be burned immediately, or if this is not practicable, as it may not always be in summer time, should be submerged in one of the solutions recommended.

DISINFECTION OF THE SICK ROOM.

No room can be disinfected as long as it is occupied, but the accumulation of disease-germs may be, to a certain extent, prevented by observance of the rules already given for the disinfection of the person, clothing, bedding, and discharges, and, above all, by the free admission of pure air. In the winter time, a good fire-place, with a brisk fire and ready inlets for fresh air; in the summer, the free passage of air through open door and windows; at all times, thorough ventilation is the great desideratum in the sick-room. After the room is vacated, its floor, walls, ceiling, and contained furniture are to be disinfected. The room should be tightly closed, and two to three pounds of sulphur for every 1,000 cubic feet of space should be burned. Parke, Davis & Co. prepare sulphur mixed with black oxide of manganese and pressed into bricks, each brick containing one pound of sulphur. These burn nicely, the manganese oxide furnishing all the oxygen necessary for the complete combustion of the sulphur. The room should be kept tightly closed during the burning of the sulphur, and for eight or ten hours thereafter. Then the windows and doors should be thrown open, and all the wood-work, and, if possible, the walls and ceiling, should be washed with a dilute solution of mercuric chloride, one part to one thousand of water.

DISINFECTION OF PRIVY VAULTS, CESSPOOLS, ETC.

The contents of privy vaults and cesspools should, even when there is no infectious disease in the neighborhood, be freely supplied with some antiseptic powder; and these receptacles of filth should be frequently cleansed. But when there is the possibility of some disease germs finding a lodgment in such places, they should be treated at once with disinfectants. The committee recommends the following: "Use one pound of corrosive sublimate for every five hundred pounds (estimated) of fæcal matter contained in the vault, or one pound of chloride of lime to every thirty pounds."

The disinfecting and antiseptic powder, the formula for which has been given, may be sprinkled freely over the surface of the matter in the vault or cesspool each day. All the wood-work above the vault should be freely washed with a solution mercuric chloride.

HOSPITAL REPORTS.

LECTURES ON INSANITY.

Delivered at the University of Pennsylvania,

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by WILLIAM H. MORRISON, M. D.

LECTURE V.

Monomania—Simple Monomania, or Monomania of Character—Delusional Monomania—Cases of Simple and of Delusional Monomania.

GENTLEMEN: The subject of monomania is one which has within recent years, especially since the assassination of Garfield, and in connection with a number of prominent cases, attracted considerable attention. It is a subject of which we should all have some precise knowledge. Some confusion exists in the minds of alienists, much confusion in the minds of many practitioners of medicine, and confusion worse confounded in the legal and lay mind in general, in reference to monomania. This is due to many causes. One cause is, that many different significances have been given to this term, monomania. It has almost been made an opprobrium from the peculiar manner in which it has been used. The common idea of a monomaniac is, or was, a person who has one false belief—in other respects being sound. This is the etymological meaning of the word, and the lay idea, the novelist's idea, and the idea of the sensational newspaper writer. You will read accounts, as I did a short time ago, of visits to insane asylums. The article to which I refer was a description of a pretended visit to an insane asylum some years ago. Among other things, the writer told how he was conducted from one part of the institution to another by an intelligent, good-looking, and physically-healthy man, who described to him the various portions of the asylum, and also gave the peculiarities of the different patients, exhibiting no trace of an unsound mind until he came to a certain patient, when, continuing his description, he said: "Now, this poor fellow imagines that he is the Redeemer

of mankind: but, poor fool, he is wrong, for I am the Redeemer of mankind—I am Jesus Christ." He then passed on to another patient, describing his peculiarities in a sane manner. This is the common idea of monomania, and while there may be some foundation for a view of this kind, you must at once dismiss yourselves of the idea of the general soundness of the minds of monomaniacs. Again, the term monomania has been applied to patients who have a single morbid impulse; but I shall discuss this under the head of impulsive monomania.

As defined by Spitzka, this is a form of insanity which is usually inherited, and is characterized by a flaw in the understanding, manifesting itself in a general direction. This is a general definition, which gives an idea of what is meant by monomania, but is not sufficient to convey a good practical idea of its varieties. It is the so-called partial insanity of some of the older writers, and even of some of the writers of the present day. It is not moral insanity, yet monomania may include some cases of moral insanity. It is not delusional insanity, and yet it includes some of the most interesting forms of delusional insanity. Nor is it impulsive insanity, yet it includes forms of impulsive insanity.

You will find that some writers discuss monomania under heads different from those which I have given you. Hammond attempts a psychological classification of insanity, and forces his subject to this idea. He is thus compelled to erect various classes of monomania under his general subdivisions of insanity. He divides insanity into intellectual, emotional, and volitional forms, these being based upon the analysis of the mind into the emotions, the intellect, and the will. Thus you will find he discusses emotional monomania, volitional monomania, intellectual monomania, reasoning mònomania, and so on through a long list. It is better I think to adopt some simple division, such as—

1. Simple monomania, or monomania without delusions.

2. Delusional monomania.

In the first place, we have monomania without delusion. This is the monomania of character. It is simple monomania. I am dissatisfied with all of the terms which are used as descriptive of this variety of mental disorder. I think that the best of all would be a term which would express the idea of monomania of character, or insanity of character. It is a peculiar defect or flaw in the character of the individual, which exhibits itself particularly in the logical apparatus, although it may show its presence in many ways. What is meant by monomania of character, simple monomania, or monomania without delusions, can only be understood by description and by seeing cases; not simply from seeing them, but by studying them minutely and carefully, and from a broad standpoint. This is the form of insanity which is so much doubted by many. Many disputed cases of it are on the border line between sanity and insanity. It is one of the forms of insanity so many cases of which get into the courts, and about which disputes arise even among the doctors. I think that no one who had seen these cases as I have seen them, and studied their histories, in some cases from the cradle to the grave and in others from the cradle to the time of examination, would fail to reach the conclusion that they represent a form of insanity.

What are the characteristics of these cases? They are, it may be, without any special impulse or delusion; they are not melanchiacs, not maniacs, nor katatonics; they are not representatives of any of the forms of insanity which we have yet studied.

I was called upon not long since to examine a case of this kind in connection with another physician. I shall briefly give you the history of this case. He is of good family, as many of these patients are. By "good family" I mean principally that the intellect, as far as the other members of the family is concerned, is good. He is now about 40 years of age. All that can be said about his childhood is that he was peculiar. He grew up to manhood and began to exhibit certain eccentricities and peculiarities of conduct and behavior. While his mother was very ill, he went through the community and invited a number of people to attend her funeral, and even had the house crowded with people coming to the funeral of his mother before she was yet dead. Then it was noticed that this man of good family and good surroundings now and then committed some form of misdemeanor without any cause for so doing. He obtained money under false pretences, without any excuse for his actions. He went to a western city, but was unable to keep any position for any length of time, although having a good education and some ability as a writer. He has occupied the position of reporter and editor on a number of newspapers, but was unable to keep any situation for any length of time. He obtained money from one of his relatives on the statement that he wished to use it in obtaining employment. Instead of doing this, he spent the money in feasting reporters and others connected with the newspapers: the result of this expenditure was that he got a few passes to the theatre. Not satisfied with this, he also forged passes to the theatre. He was arrested for forging the passes, and there was a great exposé of the whole matter. He was sent to an asylum.

In New York he again obtained money under false pretences, was arrested, and was sent to the penitentiary. He has been in three or four asylums, in a county penitentiary, and other penal institutions. He has done many things to try to gain notoriety. His strong personal characteristics are intense egotism and vanity. He seems to have no appreciation of the distinction between the truth and a lie. I believe that in the interviews I had with him he told more outrageous lies, with more coolness and appearance of truth, than I have heard from any other individual in the same time. So striking is this characteristic in these individuals, that they impress upon others the apparent truthfulness of their statements, and thus interest others in their statements. It is for this reason that worthy persons —clergymen, physicians, lawyers, philanthropists —have been induced to believe the representations of such people, and fight their battles for them. They can lie so plausibly, give so complacently a history which is entirely the opposite of the truth, that almost any one would believe them. As for the occurrence of distinct delusions in patients of

this kind, it would often be difficult to make a point of this. They have delusions as to their own importance. Their reason for doing this, that, or the other thing, is based often upon a delusive idea.

Guiteau was undoubtedly another case of this kind, but his case has been so much discussed and described that it is hardly worth while to go into it now. Guiteau had all the peculiarities of a man with the monomania of character. It is doubtful whether he had the delusions which he claimed to have. His was one of those cases in which a mam who was really insane claimed to be insane in a way in which he was not. This is my own view of his case, and it is the view which is held by many. He claimed and urged upon his counsel to base his defense upon the idea that his crime was committed under an inspiration from the Lord—an Abrahamic inspiration of some kind. His real delusive state was as to his own importance, as shown in in his application for positions for which he had no qualifications or claims. He applied for, and supposed that he would get positions as far removed from him as they were from any porter in the streets of Washington. A certain degree of erotomania was exhibited by him. Instances came out in the investigation of this case in which he tried to force his attentions on women high in social position, and to whom he was utterly unknown; he even imagined that they reciprocated his affection. I will not dwell here any further on this case. I have discussed it more fully elsewhere.*

As a rule, these monomaniacs are not possessed of much real intellectual power. It is sometimes strongly averred otherwise. Those who come in contact with them but casually sometimes get the idea that they are people of wonderful ability, but it will generally be found that it is simply an appearance of brilliancy which has no real basis. During the progress of the Guiteau trial, it was often said that he was too smart to be crazy. A careful consideration would, however, show that he was far from being even "smart." The very interruptions which he made, and the varying methods by which he endeavored to free himself from the consequences of his crime, were opposed to this idea. The brilliancy which is present in these cases is merely an occasional brilliancy of speech. This is not uncommon, but real intellectual power is usually wanting.

We had a reasoning monomaniac at Blockley for a few weeks. She, like these other individuals to whom I have referred, had the appearance of intellectual ability, but to use her own words, "She had been at all kinds of labor, and although she was good at all, she never succeeded at any. Although acknowledged to be the best book-canvasser in the country, she could not make her living." So she told me how she went from one business to another. She was egotistical beyond all measure. When first admitted, she was put into the ward for nervous diseases, where there were about twenty-five or thirty other patients. In about five minutes she remarked that she thought she would have a room somewhere else, as she did not care about mingling with the Irish trash, and began to raise a row. She was a source of interminable trouble, and at last we sent her to the out-wards. She finally was dismissed from the hospital, and I thought we were well rid of her, but three days later she came to my office and made a great fuss. She was at the Pennsylvania Hospital, but they, sharper than we were, got rid of her in twenty-four hours. She then went to the mayor with charges against the nurses and the managers of that institution. She was, I believe also at the Presbyterian Hospital.

A patient of the same kind came to the polyclinic some two or three months ago. I will give you the history which I obtained in part from one of his friends. In Ireland, he was being educated for the priesthood, but before he had finished his course, he left college, probably in consequence of his mental peculiarities. He then began teaching languages in Ireland. He was tolerably well educated, and had a good memory for poetry. He appeared to be better educated and to know more at first sight than he really did, as is the case usually with these individuals. He was always eccentric, excitable, and irritable. He was egotistical and overbearing, and would talk most of the time of himself, his abilities, and his troubles. When he came to this country, he went into the liquor business, and although he had good financial backing, he soon failed. On account of his overbearing manner, no employee could stay with him. He then went to New York and served a short time as reporter for one of the large dailies. One or two notorious sensational interviews of a Presidential campaign were largely the product of his imagination. He finally got into a condition in which he was absolutely unbearable. He was excitable, always talking about himself, and yet sometimes he seemed to be aware that there was something wrong with him.

Let me say a few words here in passing about what is sometimes termed *emotional monomania*. When monomania takes the emotional form, any one of the emotions may be the one affected. It may, for instance, be that of fear. I have one patient, in particular, who is so terror-stricken by a thunder storm that she passes almost into a maniacal condition. Then there is the dread of hydrophobia. I have two patients who suffer from this peculiar form of mania. Both are ladies. I have known one of them to become convulsed at the sight of a dog. Her whole life, and the lives of those around her, are made miserable simply because she is possessed with this special idea. Some individuals cannot go into an open space without becoming terribly agitated or getting into a half maniacal condition. There is also the opposite condition—the fear of closed spaces. One of the best illustrations of such a space, and one most likely to reveal the trouble, is a hotel elevator.

Instead of this form of morbid fear, any one of the special peculiarities of the individual may be developed into an insane state. Jealousy, avarice, pride, or any of the emotions, may become exaggerated to an insane degree, and produce emotional monomania. I have one patient who has an insane fear of having cheated some one. She scarcely ever purchases anything without being worried for hours, and perhaps for days, with

* Transactions of the Pennsylvania State Medical Society for 1882.

this fear. I have another patient who owned a large plantation in the South, and was an intelligent and highly educated man, greatly respected in the community in which he lived. On pay-day he would pay off his hands, and he had never been known to make a mistake, and yet he would become almost distracted for fear that he had made a mistake and cheated somebody.

Let me not mislead you. If you study these cases carefully, you will find that the special manifestations to which I have referred are connected with some general evidences of perverted mentality. I should not consider an individual, simply because he or she exhibited these symptoms of this sort, as insane in the ordinary sense of that term, and certainly not in a legal sense. This is only another illustration that sanity and insanity are closely related. One may be at one end of the scale and another at the other end, and between the two there are very many grades.

Delusional monomania is a form of insanity characterized by the existence of delusions of a systematized character. In some of the books you will find these cases considered under other heads than the one which I have given you. They are sometimes classed under the head of delusional or chronic delusional insanity. This term, however, is not a good one; it is too broad, and might embrace other special forms of insanity, not strictly monomania. Clouston treats of these cases under the head of *states of fixed and limited delusion*. This is a good general designation.

Monomania with delusion is the more common form of monomania, or, at least, the form more commonly recognized as insanity. A patient with simple monomania may sooner or later become the victim of monomania with delusions; or I believe that he may by education, training and treatment be delivered from the condition of monomania.

Certain peculiarities about monomania with delusions, enable it to be diagnosticated from other forms of delusional insanity. The delusion may be either expansive or depressing. At one time it was thought that monomania was a form of insanity in which the patient had only ambitious and expansive delusions. The term *megalomania*, still sometimes used, was applied to this condition. But further investigation showed that the monomaniac might have depressing delusions. The delusions of melancholia are depressing. The delusions of mania are expansive, and those of dementia paralytica are usually expansive. The delusions of monomania have this peculiarity, and it is this which stamps the case as one of monomania. They are, as I have already stated, what are termed systemized or organized delusions. The patients can reason about them in a way of their own, it is true. They can tell you why they are the commanders of armies, the heads of the church, the victims of conspiracy, or the suffererers from spiritual agencies. They will describe their inventions to you, and show you that you are wrong and that they are right. This is the striking peculiarity of monomania. In mania a man has an expansive delusion, but one minute he is a great man, he is very rich, or very strong, and the next minute he is something else. He does not stop to explain why he is strong or rich or great. The paretic dement also is worth $10,000,000 this minute, and $50,000,000 the next; one minute he is a king, the next something else. A monomaniac is a king, and he never altogether loses sight of the regal character which he has assumed.

The Germans have a word meaning a "fixed idea," which they apply to cases of this kind, and which also expresses the peculiarities of the patient. In this fact we find the justification for the use of the term monomonia. I tried to explain this at the beginning of the lecture. You must not get the idea that a monomaniac is one who has but a single fixed idea or delusion, and is absolutely sane in every other respect, yet it is a fact that the flaw is usually shown in one general direction. Sometimes the delusion is so prominent that it overshadows everything else, and hence the layman, and sometimes the physician, can see nothing except that the man imagines that he is the pope, or a king, or the Almighty. If, however, the character and history is analyzed, other things will be found showing that the patient is insane. Although the delusion is fixed and limited at one time, it is possible for it to change. It does not change from moment to moment as in melancholia. In monomania, a patient who has had in the beginning the delusion of suspicion and persecution may at another time have delusions of aggrandizement or of unreal greatness; but the change is not usually a sudden one.

In delusional monomania the delusions can in most cases be classed, as they have been by Clouston* and others, under three heads: (1) Delusions of unreal importance; (2) delusions of suspicion and persecution; and (3) delusions of unseen agencies.

Many of those known as "cranks," are cases of delusional monomania. Personally, I deprecate the indiscriminate use of this term "crank," applied in this way. Many seem to use it simply to give them a way of escape from the diagnosis of insanity. Philadelphia has and has had its quota of these people. I well remember when a boy seeing one of these characters at the Falls of the Schuylkill. He was known as the long-haired prophet, from the fact that he never cut his hair, and went around the streets without a hat. He was given to preaching and taking up collections. When the receipts were sufficient, he would often drink too much and get before the court before he had time to recover from the effects of his potations. On such occasions he would defend himself, and rebuke the audacity of the court for "rebuking the Lord's anointed." On one occasion, when sentenced by Judge Parsons to thirty days' imprisonment, he raised a great laugh by earnestly declaring, as he was being removed, that "God made religion, but the devil made Parsons."

A man wanders about town who has been to see me several times, and who believes that his wife is trying to poison him by putting poison in his drink and food. He is intelligent, and has studied up the action of poisons, and certain symptoms which he presents are attributed by him to the effect of poison. On one occasion he took a substance to Dr. Leffman for analysis, but the doctor soon discovered that he had to do with

* Clinical Lectures on Mental Diseases.

a delusional monomaniac. A woman, whom I also know well, believes that she has been poisoned by the nurses at the Pennsylvania Hospital, and that she is being kept under mesmerismic influences. She believes also that she is a clairvoyant, and that she is connected with the royal family of England.

Another of these characters was Captain McC., a Delaware river pilot. He had the delusion that he was the sole heir of Jonathan Dickinson, who had owned about half of the ground of the city of Philadelphia. During the time that the river was open to navigation he devoted himself to his occupation of pilot. As soon as the river became closed with ice, he would every morning go to the office of the Recorder of Deeds and spend the day in copying deeds. He attended auctions of real estate, and when a lot was knocked down to the highest bidder, the Captain would warn him against completing the purchase, as he had the title to the estate, and no deed could be given. On other subjects he appeared to be sound, and was regarded an unusually shrewd man.

"Mad Dallas" was another well-known character in this city. He resembled Vice-President George M. Dallas. Whilst sane on all other points, his desire to look like the Vice-President soon affected him so that he at last came to believe that he really was Mr. Dallas, whose walk, dress, and manners he affected. Every day he would walk to the steps of the State House, and deliver a disconnected address to the crowd which would collect. He would then go to the steps of the Custom House and repeat the same harangue.

Another living Philadelphian believes he is a lineal descendant of Patrick Henry. Possibly there is some of the blood of Patrick Henry in his veins, and he certainly says so with much emphasis. He is a great man in his own estimation, and thinks that he is very eloquent.

In future lectures I will call your attention in more detail to some remarkable cases of monomania, both simple and delusional.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, June 11, 1885. The President, Dr. Shakespeare, in the chair.

Dr. H. R. Wharton presented a large tumor removed from the posterior portion of the left thigh of a patient in the University Hospital, under the care of Prof. Ashhurst, with the following history: Geo. H——, aged 32 years, whose father is still living, and whose mother died, when he was an infant, of meningitis, whose brothers are living and healthy, noticed some eight years ago a small tumor appearing on the posterior portion of the left thigh, about six inches above the popliteal space. Since that time it has gradually increased in size, until at the time of his admission to the hospital it presented itself as an oblong tumor larger than a man's head. The growth of this tumor was accompanied by paroxysmal attacks of severe pain. He could not remember ever having received an injury at this portion of his body. The tumor was enucleated without difficulty, and in so doing about six inches of the sciatic nerve was laid bare, which was directly in contact with the tumor; a portion of the semi-tendonosus and biceps muscles, were stretched over the tumor.

Upon examination, after removal, the tumor was found to consist of one large cavity containing a reddish-brown fluid, surrounded by a thick fibrous wall, varying in thickness from an inch to two inches, and at points presenting numerous points of calcareous degeneration; the inner surface of this wall was lined with irregular flocculent masses. Microscopical examination proves it to be a spindle-celled sarcoma, with areas of calcareous degeneration scattered through it.

The principal points of interest in this case are the large size of the tumor, the slow course of its development, the ease with which it was removed without injury to the surrounding structures.

Dr. Tyson said that he was much interested in the cystic feature of the tumor. It would be interesting to determine if this cyst—which is a typical example of the cysts by softening—has an endothelial lining. He also asked the nature of the fluid contents.

Dr. De Schweinitz replied that he had been foiled in his efforts to make satisfactory sections by want of time for decalcifying the growth. He had determined, however, that it was unquestionably a spindle-celled sarcoma. The cyst's contents had been spilled during the operation, but were of a chocolate color.

Dr. Barton said that at the previous meeting Dr. Nancrede had exhibited two growths with a similar clinical history and analogous histological structure. It would be interesting to examine both growths with reference to the character of the walls of the blood-vessels, as suggested by Dr. Nancrede, to ascertain if any light could be thrown upon the non-malignancy of the so-called recurrent fibroid tumor of Paget.

Dr. Nancrede remarked that he had at the previous meeting specially called attention to the fact that the *so-called* recurrent fibroid of Paget was a small spindle-celled sarcoma. The position which such growths occupied, viz., the subcutaneous connective tissue, did not seem to him as had been suggested by Dr. Stimes, a satisfactory explanation of their non-recurrence. He was under the impression that a careful study of the histology of their vessel walls could demonstrate that they more closely approached those of a fibroid tumor than those of other sarcomata in not being merely channels through the tissue, directly—or almost directly—in contact with the tumor-cells. Dr. Nancrede thought that the term "recurrent fibroid" was a good clinical one, as applied to a certain class of sarcomata, since other tumors much resembling them in histological character pursued a far different course.

Dr. Tyson said that he had early made study of these growths, first known as fibro-plastic tumors of Lebert, and later, named by Paget "recurrent fibroid," but now correctly included among the sarcomata of Virchow. Dr. Tyson thought that the explanation of its non-malignancy was found in the fact that the physiology of sarcomata varies greatly in this respect, some being scarcely more so than certain fibromata, while others vie with the worse cancers in this

characteristic. The former are represented by the hardest of the sarcomata, which again are the small spindle-celled, which may be said to be the type of the recurrent fibroid of Paget. He agreed with Dr. Nancrede that the term was a good clinical one, designating a small spindle-celled sarcoma recurring in loco, but seldom by metastasis.

Dr. Formad said that no true tumor ever had arteries or veins; their blood-vessels were merely blood-channels, without muscular walls, even in fatty tumors. The cancers are an exception to this; they have true blood-vessels and nerves, hence are painful.

Dr. Nancrede replied that, as Dr. Formad's statements were totally at variance with all reliable observers, he was not prepared to accept them at present, and still thought that careful study of the histology of the vessel walls in the various sarcomata might reveal something of practical interest.

Dr. Formad said that, to him, the relative malignancy of these growths was plain. The spindle-cells can never move from their position, especially if the blood-vessels are small. The small round-celled sarcomata have small cells and are more vascular, and, hence, are very malignant, *i. e.*, give metastasis. Giant cells never travel.

Dr. Shakespeare said that the suggestions of Drs. Nancrede and Barton as to a possible difference in the blood-vessel walls of sarcomata of differing malignancy, was doubtless based upon the well-known fact that these growths become generalized through the blood-channels. It seemed to him a matter of interest, and also raised a point which might be found of importance if properly investigated, as explaining the clinical differences. It is indeed true that the tendency to malignancy from metastasis was in large part due to the ease with which cells could be detached from their place, and this has as much to do with metastasis as the supposed mobility of elements. As to the condition of the vessel walls in recurrent fibroma, he was very sure that in the primary tumors, which have been, after removal, diagnosed as pure fibromata with numerous endothelial cells along the bands of fibrous tissue, recurrences have shown a change of type to perfect sarcomata; yet the blood-vessels in the first were those of connective tissue, while in the second they have the character of simple blood-channels.

Dr. Hughes would like to call attention to the theory of a late German observer that all sarcomata arise from the endothelia of blood-vessels. It is then easily understood how they become generalized; the cells arising from the endothelium setting up the same change in the endothelium wherever they touch, while cells derived from other structures will have no effect. This distinction might be made between sarcomata remaining local and those becoming generalized, that the former arose from fibrous tissue and not from endothelium.

Dr. Nancrede desired to say in conclusion that he was of course perfectly familiar with the fact that mobility of cells had much to do with malignancy, but he felt compelled to positively deny, upon the basis of experience, the so-called fact so positively asserted by Dr. Formad that large spindle-celled sarcomata never can become generalized because, from the form of their cells, they must "stick" in the vessels. He had presented a specimen to this society some years since of the most malignant growth that he had ever had the misfortune to deal with (here followed history). He believed that Dr. Formad examined the specimen, and had not then dissented from his opinion. He would relate other instances presented to this society, but further remark was unnecessary, since all other observers except Dr. Formad had repeatedly called attention to the special malignancy of large spindle-celled sarcomata, except in certain situations. He would suggest that positive statements founded on any one observer's experience were apt to be delusive.

Specimens from a Case of Pneumonia.

Presented by Dr. M. H. Fussell.

The subject from which the specimens were removed was a child, æt. 7 months, with following history: Mother is syphilitic, was under treatment for perforating ulcer of palate at the time of death of child. Had previously had a syphilitic iritis.

I had treated the child itself for snuffles and a syphilitic eruption. On the 2d of May child suddenly taken with convulsion. He had three more before I saw him on the 3d.

At first visit, aside from a little dullness, there was nothing wrong that could be discovered. Slight rise of temperature (99.5°). No eruption; no lung symptoms; pupils were normal. He was put on iodide and bromide of potassium, continued to have convulsions until midnight of same day, having passed through eight in all.

May 4. Temperature normal. Still nothing abnormal noted.

May 5. Temperature had risen to 101.8°, expiration hurried, a few fine rales noticed over both chests.

May 6. Respiration 60, pulse 160, temperature 100°. Physical signs of a capillary bronchitis.

May 8. Blowing breathing noted over right chest posteriorly, some dullness in same position. A friction sound was also noted. The crepitant rale was absent.

May 10. Temperature 103°. Blowing breathing and dullness over right chest, especially posteriorly. Child looked remarkably well, was bright, and took notice of parents. When sleeping he had an "expiratory moan."

May 13. Lay in stupor all day. Pulse 180, respiration jerky and 80 per minute. Died at 8 o'clock on 14th.

Post-mortem.—On opening thoracic cavity, the lungs had not receded, but almost met in median line. The edge of the lung was very light color. Left pleural cavity contained a small amount of purulent liquid. Lung connected to chest wall by a few recent adhesions, easily broken down. Left pleural cavity almost entirely obliterated. On separating the lung from the chest wall, the latter had the appearance of an abscess cavity. There was no liquid exudate in this side. Between the base of the heart and the overlying lung was a patch of puriform membrane, size of a nickel five-cent piece. The entire right lung, with the exception of a strip one-half inch deep, extending along the anterior edge, is consolidated.

The pleura is converted into a puriform membrane one-half line in thickness, over the entire lateral part of the lung, covering a surface of about two and one-half by three inches. A strip of similar membrane is along the posterior edge. All the lobes of the lung are united by membrane. There is also a patch on the diaphragmatic surface. On section of the consolidated portion of the lung a purulent liquid exuded from several bronchioles. The anterior crepitant edge was filled with a frothy liquid.

Left Lung.—Crepitant throughout, except a small portion of the base. Pleura converted into a thin membrane in different portions.

Pericardium.—Was filled with a serous fluid; both surfaces roughened. Over the base of the heart, just under the position of membrane between the lung and the pericardium, was the seat of greatest amount of disease, as though this had been the starting point of the pericarditis. The lower surface of left ventricle of heart was covered by a thin puriform membrane, which was easily detached.

Heart.—The right ventricle filled with a chicken fat clot, which extended into both branches of the pulmonary artery. Left ventricle contained a clot which extended down aorta two inches. Valves all normal.

The abdominal viscera were all normal.

The head was not examined.

The microscope shows the consolidated portion of lung to be the seat of a typical catarrhal pneumonia. The alveoli are partially or entirely filled with epithelial cells. The left lung showed a microscopic picture that might be expected in a case of capillary bronchitis.

This case interested me from both its clinical and pathological aspects.

Clinically, as to what relation the convulsions had to the lung trouble. It was not until the third day after the first convulsion that any evidence of lung trouble appeared, and until that time the patient was not apparently seriously ill between the convulsions. The lung lesion was not *overlooked* until the third day, because I had made a careful examination each visit. At first I supposed it likely the convulsions were due to the syphilitic taint, because of the absence of anything else to explain them, but the subsequent history of the case I think proved that they actually marked the beginning of the lung trouble. The entire absence of any cerebral symptoms in the progress of the case would go to prove this.

Pathologically, the case is interesting from the unusual amount of time involved in the pneumonic process, for it is the rule in cases of catarrhal pneumonia to have scattered patches of consolidation, instead of, as in this case, an entire lung. It is also interesting to trace the sequence of the lesion found. Doubtless the first trouble was a bronchitis, this was soon followed by the pneumonia, which in turn gave rise to the pleuritis. The pericarditis doubtless arose from the irritation caused by the inflamed portion of pleura overlying the base of the heart, for immediately under this spot is the seat of the greatest disease in the pericardium, and here the disease spread both by continuity and contiguity of tissues.

Dr. Musser said that he could recall a case in some respects very similar. It was one of purulent pericarditis and pleuritis in a child aged 8 years, who had been rendered ill by exposure to cold seven days previous to Dr. Musser's first visit. In the early history there were nervous symptoms so prominent as to lead to a diagnosis of cerebro-spinal meningitis. During the first week of Dr. Musser's attendance, typhoid symptoms were marked, rapid respiration, extreme dyspnœa, rapid pulse. Purulent pleuritis was proved by the hypodermatic needle. Under stimulants the child improved, but occasional dysphagia, pulsation of the veins of the neck, evanescent and later persistent aphonia, were noticed. The heart was not displaced. Dr. Musser did not make out the pericarditis. The child died suddenly of heart-clot. At the post-mortem pus was found in the left pleura and pericardium, and no connection or evidence of extension such as was found in Dr. Fussel's case was detected here. The pericardial effusion had been overlooked. What then would have been the result of pleural tapping? The amount of pericardial effusion would certainly have influenced unfavorably the withdrawal of fluid from the pleural cavity—sudden death resulting. Hence a pericardial effusion should be looked for in all cases of pleural effusion, and in its recognition stress should be laid on the non-displacement of the heart, the absence of the apex-beat and impulse, the presence of the pulsating veins in the neck, as well as aphonia and dysphagia—pressure symptoms arising from a large pericardial effusion.

Two Specimens of Sarcoma of the Choroid.

Presented by Dr. G. de Schweinitz.

Dr. William L. Norris kindly permits me to exhibit these specimens, both the patients from whom they were removed having been under his care, the one in private practice, the other in the University Hospital.

J. McT., aged 21, applied for treatment at the Eye Dispensary of the University Hospital three weeks ago. He stated that for three months the vision of his left eye had been gradually diminishing, and for the last month the eye had been totally blind. This loss of sight was accompanied by no pain in the eye, neither did he suffer from headache or ciliary neuralgia, nor was his own general health or nutrition in any way impaired. His occupation was that of a weaver, but there was no history of injury or inflammation. He was examined by Dr. S. D. Risley and myself, and the following account is taken from Dr. Risley's description at that time: The vision of the right eye was normal, $\frac{20}{XX}$; in the left eye there was absolutely no light perception. The pupil under the influence of a solution of hematropia is dilated widely, but not so completely up and in as elsewhere. Using transmitted light, the eye looking directly in front, there was not the slightest reflex from the eye-ground. When the eye was slightly turned down, a small area of the ordinary red reflex was seen below, shut off above by an abrupt dark line, curved downward. In this space detachment of the retina was easily detected. Oblique light showed a reddish-brown mass occupying the upper and inner half of the eye-ground, coming almost to the posterior plane of the iris, so near as to apparently exclude the

lens. This, however, was present and not opaque. When the eye was strongly rolled down, the upper lid raised, palpation over the ball detected an area of increased resistance and density as compared with the remainder of the eye. Over this region the perforating branches of the anterior ciliary vessels were enlarged and markedly tortuous. The general tension of the ball was not increased apparently. The diagnosis of intraocular tumor was made, and the patient advised to have the eye-ball enucleated. To this he consented. Dr. Norris performed the operation. The optic nerve was cut off one half inch from the ball, and the succeeding hemorrhage rendered the tissue about the oblique muscle so tense as to make it doubtful in the case of the superior oblique whether this thickening was due to escaped blood or infiltration of the new growth. This suspicious orbital fat was removed. On section of the eye the cavity is seen to be occupied by a melanotic sarcoma growing from above and out, leaving a small space posteriorly and below, with attached retina and subretinal fluid.

The second case was removed by Dr. Norris from a girl, aged 18. The history of the duration of the tumor is deficient. Here the new growth almost entirely filled the eye. The section which I exhibit to-night shows that the growth is composed of round and spindle cells, many of the cells of an epithelioid type, and portions of the tumor separated into an alveolar arrangement by a fine vascular structure. The tumor may be classed as an alveolar sarcoma. The optic nerve entrance shows atrophy of its elements, but no true infiltration in the new growth. A year after the operation no return *in situ* had occurred.

Dr. Tyson had examined the specimen with interest, and was at first at a loss to name the growth, as there were round cells of a connective tissue type, epitheloid cells, and some suggestions of an alveoloid arrangement.

Dr. Formad thought that the growth should be classed as an alveolar sarcoma.

Dr. Tyson thought it was an alveolar sarcoma, the sarcoma carcinomatoides of Rindfleisch and others.

Dr. Shakespeare said that the growth was a most extensive combination of epithelioid and connective tissue elements, evidently springing from the choroid, leaving the hexagonal choroidal elements untouched. There was also an evidence of dilatation of the blood-vessels, and filling up of their lumen with detritus and, perhaps, proliferated endothelial cells and leucocytes. In one portion of the growth there is a channel with as perfectly formed cylindrical cells as is an adenoma or cylindrical epithelium. The fact that the patient has lived over a year since the removal of the eye, free from disease, would lead us to believe that the growth was benign. Whether it can be positively classed as a sarcoma was doubtful. By following around the section there can be no doubt that in the portion represented by the section the retina is not affected, as the hexagonal layer of choroidal cells can be traced unbroken.

Dr. De Schweinitz said that the retina was certainly not affected.

Dr. Shakespeare said that the non-recurrence of the growth was also against its sarcomatous nature, as the alveolar sarcoma was the one most certain of all to become generalized; besides, this growth contained germinal epithelial cells.

The Treatment of Writers' Cramp.

Dr. R. P. Robins thus spoke to the Philadelphia County Medical Society, March, 1885:

It would be supererogatory, I think, to give to the members of this Society any detailed account of the symptoms of the disease commonly known as writers' cramp, as most of those to whom these remarks are addressed have doubtless seen, and, perhaps, been baffled in the treatment of cases of that very troublesome and annoying neurosis, in one of its three forms. It will be necessary for me, however, before discussing the methods of treatment which, in my hands, have met with varying success, to touch somewhat upon the mooted question of the pathology of the disease. I spoke of writers' cramp as a neurosis; in this view of the nature of the disease, I would be supported by many of the authorities to whom you would be likely to refer; but you would also find almost an equal number who would not regard the malady as a neurosis at all, or at least would quarrel with any theory which located the lesion in any part of the central nervous system. As far as I am aware of the history of the disease, and I have lately given the matter considerable study, there is no record of any case where an autopsy gave opportunities for an exact determination of the seat of the lesion, and it does not seem likely that we are now any nearer the solution of the problem by this means, than we were in 1857, when Zuradelli, of Pavia, published his brochure "Del Crampo degli Scrittori," in an Italian journal. The writer was strongly of the opinion that the cramp was a muscular, rather than a centric disease, his theory being that there was a debility of certain muscles, generally employed in certain coördinative movements, and a secondary spasm of opposing muscles. Even so late an essayist as Dr. Poore, of London, to whose admirable little book, "Electricity in Medicine and Surgery," we owe many excellent suggestions as to the treatment of many diseases in which the battery can be used with advantage, does not array himself strongly in opposition to this theory, and I am aware that many of those whom I am addressing to-night probably hold the same opinion. On the other hand, an array of authors, Duchenne, Erb, Althaus, Solly, and others, very emphatically give, as their dictum, the conclusion that the disease is due to a lesion of some point of the nervous centres, although they are divided

as to its localization. Dr. Solly is the only one who definitely gives it as his belief that the lesion is to be found in the cervical portion of the cord, and that there is a granular degeneration of what he calls the "nucleated vesicles."

I have said this much regarding the possible pathology of the disease, simply as prefatory, because, of course, the nature of the treatment will be influenced to a greater or less extent by the views which you hold as to the ætiology of the disease, although I may say for myself that my opinion, formed after some experience with a number of obstinate cases, and also after considerable investigation into the literature of the subject, strongly tends towards the conclusion that the lesion is to be found just where Dr. Solly says it is, in the cervical portion of the spinal cord; it is with this belief that I have to suggest a course of treatment which, I think, will benefit any case, if the disease be taken in time.

As I have intimated, I pass over any attempt to describe the symptoms of the disease as entirely unnecessary, only noting that all cases will present themselves under one or the other of three forms. They will be either (1) spastic, (2) tremulous, or (3) paralytic, and these three divisions will, to you, carry their explanations in their names. Nor do I think that the variety in form would influence the method of treatment, which could be applied to any of them indifferently.

Now, there are three factors in the treatment of writers' cramp, or, indeed, of any of those analogous conditions of incoördination, which are met with in tailors, telegraphists, pianists, milkers, and others. One of these factors is essential, the other two are simply effective methods of local stimulation. I refer to *rest*, *electricity* and *massage*. I will speak of these *seriatim*.

1. Your patient must have absolute rest, not necessarily of the whole body, but absolutely and entirely of the affected muscles, as far as those particular movements of coördination are concerned, whose abuse has brought on the attack. It is necessary to be very firm in demanding this element of treatment from your patient. Various objections will be urged; the disease is to be met with amongst a class of men upon whose pen depends their livelihood—to suggest rest to them is to suggest starvation. Your only answer can be the unfavorable prognosis, which is unchangeable in all cases where you cannot secure this factor. I have no hesitation in saying that no case can possibly recover, unless time be given to the degenerated nerve-centres to regenerate themselves; and that they assuredly will not do, if the demand upon their functional activity continues. In some cases I have been accustomed to order the arm to be carried in a sling for a week or so, to remind the patient that all writing is to be shunned; with the majority of patients this suggestion will be unnecessary; of course, I need hardly add, any other coördinative movement, involving the same group of muscles, may be indulged in with impunity.

2. Electricity is an important factor in the treatment, but I do not regard its use as absolutely necessary in simple uncomplicated cases, when taken early enough. I believe, however, that it hastens recovery, and therefore should always be employed. The continuous, and not the faradic, current should be used. The latter has been a favorite amongst the Germans, so high an authority as Dr. Erb sanctioning its use; but I am inclined to think, with Dr. Poore, that the best results are most certainly obtained by the employment of the continuous current. A weak faradic current may be strong enough even to destroy the electric irritability of the worn-out muscles in writers' cramp. Galvanism, to my mind, offers the safest and best mode of electrical treatment, and one which, in favorable cases, is sure to be followed by good results. The current should not be so strong as to cause muscular contraction, but should produce a slight tingle at the ends of the fingers when circuit is made or broken; It should be used every day for the first fortnight. after that time, the séances should be gradually diminished in number until the end of the second month, when they may be discontinued in a typical case where recovery progresses without intermission. But the disease varies so much, some cases yielding easily to treatment, and some proving so unreservedly obstinate, that it is hard to lay down an iron-clad rule with regard to the administration of the electricity. With regard to the method of its administration, I think the suggestions of Dr. Poore so admirable that there seems no good reason for departing from his method of treatment. He says:

"One pole (the positive) is placed, let us say, over the axilla, and the other over the ulnar nerve just where it leaves the biceps muscle *en route* for the olecranon. The strength of the current is short of that which causes muscular contraction, but is just sufficient to make the patient conscious of a tingle in the end of the little finger when the circuit is made or broken. The patient is made to exercise the interossei by separating and approximating the fingers rhythmically. Take another example: The positive pole may be placed over the median nerve at the inner border of the biceps, and the negative over the body of the flexor longus pollicis, while the patient is made to flex rhythmically the distal phalanx of his thumb; or, again, the positive pole may be placed in the axilla, and the negative over the musculo-spiral nerve as it turns forward alongside of the supinator longus, just above the bend of the elbow; and the patient is then made to supinate the hand or extend the fingers rhythmically."

Of course, this plan laid down by Dr. Poore is subject to variation, but the general scope of treatment by electricity which he suggests, should not be departed from. Dr. Erb, indeed, advises galvanization of the head, cervical sympathetic and cervical cord. This does not seem to me to be necessary, but there is no reason against its employment.

3. I approach the subject of massage in the treatment of these professional over-movements with considerable diffidence, because of the extravagant claims that have been made for it, as a curative agent in these diseases; yet I must say that the statistics which have been published, both in America (by Dr. Douglas Graham, in his Practical Treatise on Massage), and abroad by different observers who have employed the method of Wolff, are very strong in favor of its use. It is claimed that Wolff has cured at least 54 per

cent. of the cases of over-movement which have come under his care. His method is endorsed by many leading continental specialists, Charcot amongst others; and since his sojourn in England, so lately as January of this year, Dr. de Watteville has reported several cases which he submitted to Herr Wolff, and whose treatment resulted in a cure. Briefly, Wolff's method "rests exclusively upon active and passive gymnastics of the fore and upper arm, upon massage, percussion, and friction of the same parts, and after a time of elementary exercises in writing, prescribed and adapted to each case by holding the pen in a definite manner. These are gone through with two or three times daily for half an hour or so at a time."

I need hardly add that when massage is employed, and it should always be employed when the means of the patient will admit of it, it should always be entrusted to a skilled manipulator; no course of shampooing, rubbing, or other manipulation by the patient or the physician, can take the place of the operations of a trained masseur. It is therefore unnecessary for me here to enter into a description of the method of its administration; Dr. Graham has done this thoroughly in his treatise, to which I refer you.

When there is a depressed condition of the general nervous system, strychnia may be employed with advantage in these cases. I have also found the acid phosphates (after Dr. Pepper's formula—see "Tyson on Diseases of the Kidney") a very valuable tonic. Calisthenics, addressed to the development of the affected muscles, are also of some value.

Finally, the physician will often be called upon to suggest some means to aid in writing, those who by reason of the duration of their disease have defied all treatment, or who are unable, for pecuniary reasons, to quit their employment, even for a brief period. Many appliances have been invented for the support of the arm and the relief of the affected muscles, but, as you are no doubt aware, the lasting benefit derived from the employment of such apparatus is *nil*, as they only serve as a means of enabling the affected arm to be used for writing, and in nowise act as a curative agent. I exhibit to you, to-night, a few of these apparatus, through the courtesy of Mr. Spellerberg, who has loaned them to me for that purpose; and one or two, which I was not able to obtain, I have endeavored to figure in rough sketches.

The first apparatus which I show you is that of M. Velpeau. As you will see, this consists of an oblong ball made of wood or of hard rubber, to be grasped by the hand, keeping it in a proper position. To this are attached a couple of half rings for the index and middle fingers. A penholder passes through the neck of the ball at a convenient place near the extremity, which can be adjusted and made firm with a thumb-screw. The picture shows you the hand grasping the ball and in position for writing; whilst this, which is a slight modification of the Velpeau apparatus, devised by Mr. Spellerberg, gives you a general idea of its shape. These two apparatus which are here at hand, are also modifications of the Velpeau, the differences being trivial, and consisting simply in a modification of the position of the half-rings, or of the swivel which holds the pen. The disadvantage of all of these instruments lies in their weight.

This instrument, of which I have a drawing, is that devised by M. Mathieu. It consists of two rings for the index finger, and a half-ring properly distanced from the others, in which to rest the thumb. These are fixed to a spring-slide, into which a common pen-holder can be easily adjusted. This is a light and easily managed instrument, but, as you may see, it gives no rest to the pronators, which are often affected with the other groups of muscles used in writing.

M. Cazenave, of Burdeaux, has invented an instrument, which is figured in this drawing. It is, as you see, a hybrid between the two which I have shown you. It has the half-rings for the index and middle fingers and the thumb, like that of M. Velpeau, and the pen-holder is held in a spring-slide with a screw like that of M. Mathieu; but it differs from the former in that the pen is held between the thumb and forefinger, instead of passing between the fore and middle fingers, and from the latter in that the supporting rings are halved instead of being whole.

This instrument, which I show you, is the invention of von Nussbaum, of Munich, and is, perhaps, the simplest, and at the same time the most satisfactory, of any which I have yet exhibited. It consists of an oval band of hard rubber, through which the fingers pass, and which is held in position by the thumb. On the upper part of this band is fastened, by its base, a grooved right-angled triangle sloping towards the fingers. In this groove the penholder is held by a screw. Writing, with this appliance, is entirely from the wrist, there being no finger movements, and the hand must, therefore, be held in complete pronation. This, of necessity, prevents the instrument from being of any use where the disease has involved the pronator muscles.

Finally, I have here a little instrument, which was suggested to me by Mr. Gemrig, for one of my patients, who was in the first stage of the disease. It is, as you see, simply a solid rubber ball, perforated at about one-third of its circumference; through this perforation a penholder has been thrust. This apparatus was used by my patient alternately with her ordinary pen-holder, and she derived much comfort from its use. It should, however, be employed only in the first stage, and before over-movements have begun.

I must, in closing, however, re-iterate my statement that no amelioration in the symptoms can be expected to be accomplished by these instruments alone, and they are only to be employed in old cases where a cure can hardly be hoped for, or as adjuvants to the rest, electricity and massage course of treatment. In the latter case, indeed, I am inclined to believe that the patient is better without than with them.

Nitrite of Amyl an Eliminator of Uric Acid; Its Employment in the Treatment of Gout.

Dr. Archibald D. McDonald thus writes in the *Brit. Med. Jour.*, May 23:

I propose to support the title of this short paper by three distinct yet closely connected statements.

1. On September 13, 1882, I attended a case of what is usually called puerperal eclampsia. After the first hour, and during three and a half hours, I repeatedly gave nitrite of amyl by inhalation, in the usual way and dose. In the course of the following eighteen hours, one minim of nitro-glycerine, of 1 per cent. solution, was four times administered, and chloroform to a limited extent, as well as an operative procedure, also marked that period. Nine hours after the last dose of nitro-glycerine, that is about 31½ hours after the first inhalation of nitrite of amyl, I drew off the urine. After standing for nearly 48 hours, it was seen to have deposited, *inter alia*, crystals of uric acid.

Then, this fact somewhat puzzled me, but I was inclined, for reasons which need not be specified, deduced from the hypothesis of authorities on the subject of this eclampsia, to look upon this as an interesting clue to a rationale of the colchicum treatment of the disease. A notice of the observations of Signori Guiseppe and Sansoni, of Turin, however, has forced me to reconsider the point.

2. Accordingly, I instituted a check-experiment, the subject of which was a healthy adult, whose urine was previously normal. The experiment, except the non-administration of chloroform, corresponded, as far as possible, to the case just mentioned. Thus, from 10:45 a. m., till 2:50 p. m., seven inhalations of 5 minims each of nitrite of amyl were taken. The urine passed at 4 o'clock, an hour after food, was of a clear dark straw-color, very acid in reaction, and, on cooling, deposited a little mucus, and copious urates. One ounce without the urates, but *plus* a drachm of hydrochloric acid, showed, after forty-eight hours had elapsed, a large deposit of uric acid crystals. Also, as in the first case, nitro-glycerine was taken.

A similar quantity, passed seven hours after the last, almost free from visible urates, similarly treated, gave what may be relatively termed a very considerable deposit; and next day (36 hours after the first drug was first administered), from the sample, a considerable amount of the crystals was obtained.

I hope shortly to narrate an experiment with regard to the effect of nitro-glycerine *per se*.

Thus I was able to confirm the statement of the Italian observers named, and also to find that the balance of fact against theory compels me now to believe that the excretion of uric acid in the case of eclampsia was, at all events, largely due to the drug employed, and not wholly to the disease, and that no deduction could be drawn from the premises as to any connection between the gouty diathesis and puerperal eclampsia, or the consequent colchicum treatment of that affection. My inquiry into the symptom had no pretense to have been exhaustive; the case, however, is pretty clearly, though not yet quite logically, proven now.

3. A practical application of this property of the nitrite of amyl as an eliminator of the gout-poison immediately occurred to me, to which I at once gave effect.

H. G., of Tue Brook, a powerful, slightly ruddy man, aged 37, had suffered from gout, and now had an attack chiefly in the ankle-joint. For four days he had had an alkaline mixture with colchicum, and had obtained some relief, also, from local treatment. At 4 p. m., on April 17, his urine was clear straw-colored; on standing, it contained a very little mucus, no other deposit. One ounce, acidulated with a drachm of hydrochloric acid as before, and set aside for forty-eight hours, showed only a very few crystals of uric acid.

That statement enables a fair judgment to be formed of the state of matters previously to the use of the nitrite, during which the medicine and special local treatment were, of course, abandoned.

The first inhaled dose of four minims was given by myself at 4:2; a faint flush and sensation of fullness in the head resulted. At 6, 8, and 10 o'clock, the dose was repeated. Next morning at 9 he was much better, but had a slight headache, which soon passed off. His urine passed at that hour showed a very acid reaction, and, being treated as above, gave what I describe, in the absence of a quantitative analysis, as a considerable deposit of uric acid. On the 20th he was able to walk, the ankle-joint being very nearly well.

Remarks would be redundant. Further research is manifestly required. I will only say that all I claim is to have established a *prima facie* case for the administration of nitrite of amyl as a rational therapeutic agent in those cases of gout in which the usual contraindications do not prevent its use. And if we can by its means procure a more than normal discharge of uric acid when an attack threatens, we may find it prophylactic as well as curative.

Cocaine in Operations for Fistulous Canals.

Dr. J. G. Barford, thus writes in the *Lancet* June 6:

The following case is interesting from two points of view: (1) as indicating the risk a patient appears to run in moving from a healthy country district to town to have a surgical operation performed, however skilfully done; and (2) the great value of cocaine as a local anæsthetic, even when considerable flesh wounds have to be inflicted, in cases where it is undesirable to administer a general anæsthestic from some idiosyncrasy in the patient.

A country clergyman, whose home is situate in an open, bracing, and exceptionally healthy locality, 600 feet above the sea, was the subject of hemorrhoids, for which he was advised to place himself under the care of one of the best known specialists for this affection. He went from the pure air of the country into a private surgical home for the purpose of having the hemorrhoids removed. No difficulty was experienced in the operation, and the inner surface of the rectum healed readily, and remains sound up to the present time. But a few days after the operation some untoward constitutional symptoms presented themselves. The temperature rose to 104°, and general febrile disturbance ensued. In a few days, pain, tenderness, and swelling displayed themselves along the perineum to the scrotum, and in due course a considerable accumulation of pus was apparent. A free incision was made, and with the discharge of pus the general symptoms improved. There was also another small accumulation of pus in the inner surface of the but-

tock, running up in the direction of the rectum. This, too, was freely opened. At the end of the fifth week from the operation, the patient was removed in one of Ridding's invalid carriages into the pure air of the country. His general symptoms had somewhat improved; but the discharge from the wounds was very sanious, and far from healthy looking; he was not making the progress a patient should do under the circumstances. His condition was one of evident septic infection. Two sinuses remained at the points of suppuration, about the depth of half an ordinary surgical probe, and leading to what appeared to be soft and easily broken-down tissue, threatening to work their way towards the rectum, or it might be into the urethra. The patient's condition at this time did not justify further operative interference. At the end of two months from the operation two other sinuses were formed in the perineum between the anus and the scrotum. One of these healed spontaneously, as, indeed, a sinus occasionally does. Two of the other sinuses communicated with each other. At the end of three months from the removal of the hemorrhoids the patient's constitutional condition had sufficiently improved to justify further surgical interference, and it was decided to lay the sinuses freely open. The patient had, however, on previous occasions proved to be such a bad subject for general anæsthetics, that their administration was thought unjustifiable: I therefore decided to use cocaine to destroy the sensibility of the part. Some small plugs of cotton-wool were saturated with a 20 per cent. solution of cocaine, supplied by Mr. Martindale, of Cavendish street, and these were inserted into the sinuses, one plug in each, and allowed to remain for a quarter of an hour. They were then removed, and each sinus laid freely open with an ordinary bistoury and director. No pain whatever was felt by the patient in laying open two of the sinuses, the patient not knowing even when the incisions were being made. In laying the third sinus freely open a considerable portion of skin had to be cut through, and while the bistoury was passing through the skin the patient displayed some consciousness of it. The skin is evidently not so ready an absorbent of cocaine as either mucous membrane or an abraded surface. If I had again to use cocaine in an operation involving the skin, I should apply a little liquid blister to abrade the surface before the application of the cocaine. Exactly one drachm of the 20 per cent. solution was used. In operations with cocaine there is but little hemorrhage, thus it is not unlikely to become a valuable remedy to restrain bleeding.

Reviews and Book Notices.

BOOK NOTICES.

Poisons, their Effects and Detection. A Manual for the Use of Analytical Chemists and Experts, with an Introductory Essay on the Growth of Modern Toxicology. By Alexander W. Blyth, M. R. C. S., etc. Vol. I. Wm. Wood & Co., New York.

This work is an enlargement and revision of that portion of Mr. Blyth's work on chemistry which treats of poisons. As one of the English public analysts, he has had ample opportunities for the practical study of toxicology, and the pages of the treatise abound in original observation, as well as reveal a thorough acquaintance with the literature of the subject. An interesting chapter is that on the "ptomaines," the cadaveric alkaloids of a poisonous character which have of late attracted so much attention with reference to the consumption of canned meats.

The volume constitutes one of Wood's series of "Standard Medical Authors," and is neatly printed.

A Text-Book of Physiology. By M. Foster, M. A., etc. Third American from the Fourth English Edition, with Notes and Additions by Edward T. Reichert, M. D., with 271 illustrations. 8vo. Philadelphia: Lea Bros. & Co.

The popularity which this physiological text-book has met, is well deserved by its convenient size, and the care with which each recurrent edition is conscientiously revised, both by the English author and the American editor. Although since the appearance of the former edition no striking discovery in human physiology has been chronicled, there is a constant advance in all its departments, and these the author and editor have been on the alert to note and incorporate in the work.

The cuts are numerous and well finished, and the manufacture of the book is of the most satisfactory character.

Second Report of the State Board of Health of the State of Tennessee. Nashville, 1885.

This well-prepared volume of 600 pages bears strong testimony to the energy and efficiency of the Tennessee State Board of Health. It shows that the Board is fully aware of the gravity of the interests which are committed to its charge. Thus we find among the articles composing the volume a careful article on School Hygiene, by Dr. D. F. Wright, and one on Physical Training in the Ladies' (why ladies'? why not woman's?) Department of the State Normal College, by the director, Mary E. W. Jones. Dr. J. D. Plunket speaks of bovine tuberculosis as a frequent cause of disease in man, and in another article gives directions for instituting ozone observations in the State. Quarantine is discussed by Dr. G. B. Thornton, and abattoirs by the same. The medical topography of East Tennessee is described by Dr. S. B. Boyd, and a report on the vital statistics of the State is furnished by Dr. Plunket. There is a report from the committee on prisons, and a general review of the field by the Secretary, Dr. J. Berrien Lindsley.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

POSSIBLE MISTAKES.

It is a well-known fact that, especially in children, pneumonia is apt to simulate meningitis. There scarcely is a text-book on the practice of medicine that does not make mention of this observation. But few cases, however, have been put on record to illustrate the possibility of such an error. For this reason the following case is very instructive, that Dr. Cadet de Gassicourt publishes in the *Revue Mens. des Malad. de l'Enfance*, January, 1885:

A boy, aged five, is suddenly attacked with vomiting and convulsions. The latter do not recur, but the former continue to the next day. Besides, a general lassitude is noted, headache, grinding of the teeth, and constipation make their appearance, and twenty-four hours later, somnolence, with gradual transition into coma, sets in. In this condition, the boy arrives at the hospital. There, besides the data already mentioned, divergent strabismus, and a mild degree of rigidity of the muscles of the neck, are plainly noticed. In consequence of these facts, and on account of the complete absence of any other indications, the diagnosis of meningitis is made, although the pulse was regular, not even slower (120 beats per minute), the abdomen not retracted, and no alteration of the pupillary reaction present. The first symptom causing the suspicion of a pulmonary malady was very plain flapping of the alæ nasi, accompanied by a frequency of respiration amounting to forty per minute. The third day after his admission to the hospital there appeared a gradually-increasing dullness on percussion at the angle of the left scapula, having first an extension of three cm., and on auscultation, the crepitant rale was plainly to be perceived. The first diagnosis was, therefore, dropped, and instead, that of acute lobar pneumonia recorded. This diagnosis seemed, also, to be confirmed during the next few days by a gradual increase—of degree as well as of extension—of the physical phenomena, until the eighth day, the whole part on the left side, anteriorly and posteriorly, gave a flat sound on percussion; only be-

low the clavicle in front of the chest, as well as at the back, a clear sound could be elicited.

Less the local state of affairs than the general condition of the little patient soon produced, however, in G., the suspicion that the boy did not suffer from croupous pneumonia, but from that rare form of broncho-pneumonia to which G. has given the name of subacute pseudo-lobar broncho-pneumonia; and it was especially the continuous lassitude which induced G. to this other change in his opinion.

The tenth day the same physical signs as had been observed on the left side also made their appearance on the right, only not being quite so extensive there; and this fact served to confirm G. in his diagnosis. By increasing asphyxia, death set in two days later.

The post-mortem examination showed a double-sided pleuritic effusion, besides pseudo-lobar left-sided broncho-pneumonia of the lower lobe, and disseminated pneumonia of the left upper lobe. and of the same lobe of the right lung.

Besides the interesting diagnostic data, the case also contributes to medical literature one more proof of the infectious character of all these kinds of pneumonia.

KRAO.

Now that the hairy little girl has made the tour of the country, and excited the usual amount of wonder in the breasts of the people and a corresponding amount of influx of profit to the showmen, it is fair to remove the cloud of mystery with which she was surrounded by her proprietors.

The story was told that she belonged to a hairy race dwelling in the interior of Borneo, and that she was, both in appearance and anatomical conformation, a fair representative of the long-sought-or "missing link." Her "keeper," as we may call the gentleman who accompanies her, took good care not to contradict this story. He went a good deal farther. On inquiry by ourselves, he stated it to be true of his own personal knowledge. He showed what he alleged were photographs of her father and mother, represented as equally hairy people, and asserting that he had learned their language, promised to send us a vocabulary of it—a promise which it is needless to say he found convenient to forget. He even showed her to various physicians, and induced the editor of one of the Philadelphia medical journals to write a long editorial description of her, well calculated for quotation and for keeping up the nine days' wonder.

The simple truth of the history of Krao is that she is merely one of those anomalies which occur in different quarters of the globe, and is not at all an example of the "missing link," or anything of the kind. She was born at Bangkok in Siam, of parents both of whom are still living, and both of whom are of the ordinary Siamese type. In her physical structure she has nothing whatever pithecoid or ape-like about her, although she has been taught to hold objects in her mouth as an ape does in his cheek pouches, and in other respects her exhibitors have tried to make the resemblance to the lower primates as marked as possible. The flexibility of the joints which she possesses is indeed curious, but as the comparative anatomist knows, this is not at all a characteristic of the members of apes. Her mental powers are fully up to the average of girls of her age, and indeed she seemed to us rather precocious, as one might expect from her public and roving life.

Such are the facts about Krao, and while she is an interesting specimen of a human "sport," to use a horticultural expression, she has no ethnological importance whatever. It is a pity that there must always be so much humbug and lying about the exhibition of natural curiosities. They should be more interesting when the precise truth about them is known.

DR. FERRAN'S INOCULATIONS.

The majority of the medical press seem as ready to reject Dr. Ferran's cholera inoculations as a boon to humanity as they were to accept Dr. Koch's comma-bacillus theory of cholera. Let us make haste slowly.

Dr. Ferran has refused to let into his secrets the

German and the Frenchman who went down into Spain to investigate his inoculations, and they forthwith rush home and denounce him as a fraud.

But hold up; Pasteur, the greatest of them all, still champions Ferran—and while his great voice is raised in his favor, and while Koch keeps silence, let the smaller fry hold their braying tongues.

We do not mean to champion Ferran, because we do not know anything about his processes further than what we read in the press; but we merely say, wait until we hear from Pasteur and Koch. All those who have gone to Spain say that the statistics are in Ferran's favor; but then, they maliciously add that the statistics are unreliable.

The secrecy with which he shrouds his processes his opponents make much of; but this he explains by saying that he is a candidate for the Breant prize, of the value of $20,000, for the best cure of cholera, and that he cannot, therefore, divulge his secrets until the decision of the Prize Commission is known. He has sent some material for inoculation to Pasteur for experiments.

Again, we say, we do not mean to champion Ferran, but we do say that after reading all that the foreign journals say on the subject, we cannot see that his claim is disproven, and we therefore say, let us *wait* and see whether Ferran is destined to become a second Jenner or not.

Notes and Comments.

Erysipelas in Paris.

A debate upon erysipelas has been occupying several sittings of the Paris Academy of Medicine, and at a recent meeting M. Verneuil summed up the conclusions arrived at: "In Paris, a few years ago, erysipelas was very common and very fatal, especially in surgical practice. The antiseptic treatment of wounds has considerably diminished it in frequency and gravity, without, however, succeeding in causing its complete disappearance; the erysipelatous endemic remains, ever ready to reproduce its epidemics, brief and restricted no doubt, but still involving a certain number of victims. It occurs in two distinct foci, the hospital and the town, which reciprocally infect each other. Antisepsis, powerful and efficacious in the nosocomial area, is almost impossible to be applied as a prophylactic measure in the urban area, that is and will long be contaminated so that, after having by every precaution purified a hospital or ward, a single case imported from the town suffices to again introduce the poison. It would be easy to prove that every year in our hospitals a certain number of patients attacked with other affections, sometimes trivial, succumb from the contagion of cases of erysipelas admitted from outside. In spite of the immense value of antisepsis, it is not applicable to all cases, and cannot prevent the introduction, dissemination, and multiplication of heterocthonous erysipelatous germs. Nor can it prevent these germs, cultivated and multiplied in hospitals, being subsequently reproduced in the town. In order to prevent re-infection of insanitary places and the dispersion of germs, to destroy the evil at its root, there is only one serious plan, viz., the isolation of cases developed within the hospital or introduced from the town. The establishment of isolation wards for the erysipelatous is a necessary measure, strenuously demanded both by science and humanity. Consequently, the Academy of Medicine demands of the authorities the immediate formation of such institutions." After some discussion, MM. Verneuil and Trélat were authorized to bring up a further report to the next meeting of the Academy.

Puerperal Convulsions without Albuminuria.

Dr. N. Vuccino, of Rodosta, writing in the Constantinople *Gazette Médicale d' Orient*, gives the case of a lady usually enjoying excellent health, except for occasional hysterical attacks, who in the fourth month of her first pregnancy was seized with a severe frontal hemicrania of quotidian type. At the end of the sixth month she was awakened one night with intense pain in the head, followed by a slight convulsion affecting the upper extremities. In the morning the writer found her suffering from general convulsions, consciousness being lost, and a bloody froth issuing from the mouth; the pulse was small and hard; but the urine was then, and continued to be, perfectly normal. Various methods of treatment having proved fruitless, it was decided to bring on the labor; which was done by injecting hot water (32°). After this had been continued for three hours and a half, the os uteri became fully dilated, and a dead child was shortly

afterwards expelled. The convulsions ceased as if by magic, and in twelve days she was able to resume her household occupations. She afterwards enjoyed good health till the eighth month of her second pregnancy, when convulsions reappeared with greater intensity than before. Chloral and chloroform proving inefficacious, the continual hot vaginal douche was again employed. In consequence of the irregularity of the contractions of the uterus, forceps were required. The convulsions ceased five hours after delivery, and in seventeen days she was again in her normal condition. She subsequently became pregnant for the third time, and during the second month suffered from some premonitory convulsive symptoms, which were increased by vaginal examination; these came to an end on the patient aborting. The author considers the case interesting, as showing how convulsions, due, as he believes, to a highly nervous condition of the uterus, may simulate those connected with renal and urinary mischief.

Cocaine in the Avulsion of Ingrowing Toe-nail.

Dr. F. Peyre Porcher thus writes in the *Med. News*, July 11:

A lady came to me after undergoing very great suffering all winter from the ingrowing of both toe-nails. She had been incapacitated for taking exercise; there was loss of sleep, and her health was being undermined.

As it was a condition precedent that there was to be *no pain*, chloroform was promised if required, and I proceeded as follows:

A four per cent solution of hydrochlorate of cocaine was instilled, drop by drop, from the point of a hypodermatic needle upon the slightly raw surfaces in the furrows on each side of the ingrowing nail of the big toe. A rag, wet with the same, was kept pressed against the upper surface of the toe, and three injections of this strength were made hypodermatically in the flesh at the base of the nail, just above the matrix. The tissues here being thin, and not very cellular in structure, probably ten to fifteen drops may have been received and absorbed.

After the lapse of fifteen minutes, the narrow blade of a fine-pointed pair of scissors was passed under the nail, which was divided to the matrix, when the two portions of nail were forcibly extracted with strong forceps, and any shreds of nail remaining at the roots were cleared out.

Having remarked that the operation was finished, the lady, who had not winced, expressed great surprise. After three days she was well enough, wearing a light slipper, to visit friends some miles in the country, and three days later returned to her home in one of the upper counties.

I had witnessed a similar operation performed by a gentleman in this city, which was successful.

A Singular Case.

Such cases are sufficiently rare to warrant the reproduction of the case which Dr. Samuel West records in the *London Med. Times*, July 11:

James C. was brought into the hospital unconscious and paralyzed, and died two hours later. He had been seen to fall suddenly in the street. The pupils were equal, but minutely contracted.

It transpired that he had had an injury to the head two years before, and since then had had pains in the head, for which he had been two months in the Doncaster Infirmary. On post-mortem examination, the convolutions of the brain were found flattened on both sides. The vessels at the base were very atheromatous. The pons and upper part of the medulla were covered with blood; this extended under the pia mater, over the upper part of the cerebellum, corpus callosum, and crown, all of which parts were softer than natural, but otherwise normal; the ventricles contained a little clear serous fluid. In the middle of the pons on the right side the tissue was discolored, and a long transverse slit was found infiltrated with blood, from which hemorrhage proceeded. The right side of the cerebellum was remarkably soft, and on section, a cavity was found, containing recently extravasated blood, from which the finger could be passed into the cavity corresponding with the slit described. This was not the source of the hemorrhage, but a laceration produced by the blood as it passed from the pons. The aorta was slightly atheromatous, the left ventricle slightly hypertrophied, but the valves healthy. The kidneys were large (right = 6½ ozs., left = 5½ ozs.), and the liver firm, weighing 3½ lbs.

A Cuban Cure for Neuralgia.

The *Lancet* tells us that Dr. Antonio L. Esperon reports in the *Crónica Medico-Quirúrgica* of Habana, Cuba, two cases of neuralgia treated with parthenin, a drug extracted from a plant known in Cuba as "bitter broom" (Escoba amarga). The first was a married woman, aged twenty three, who, after an abortion, became subject to severe pain at the menstrual periods affecting the iliac fossæ. In one of these attacks, when the author attended her, he found morphia,

chloral, and bromide of potassium useless, but that relief was afforded by quinine. In a subsequent attack, when there were rigors, headache, pyrexia, and furred tongue, ovarian neuralgia was diagnosed. A subcutaneous injection of morphia was given, and afterwards one-sixth of a gramme of parthenin every two hours was ordered. At the next visit it was found that after an hour the effects of the morphia began to pass off, and the pain had returned. The medicine had not been administered. After three doses of the parthenin the pain disappeared, and did not return. The second case was that of a colored woman with severe coccydynia. Morphia only relieved this temporarily, but after a few doses of one sixth of a gramme of parthenin in pills the pain permanently left her. The writer has also employed parthenin in many cases of facial neuralgia with great success. He believes that it is especially indicated in neuralgias of malarial origin.

Terpine and Terpinol.

The Paris correspondent of an English exchange tells us that at a recent meeting of the Société de Thérapeutique, Dr. Dujardin-Beaumetz recalled the fact that in treating turpentine with an alkaline carbonate, a substance is obtained to which the name of "terpine" has been given. This substance has been experimented with by Dr. Lépine, of Lyons, who ascertained that it is endowed with very marked diuretic properties, and that it modifies the bronchial secretion in old catarrhal affections. Dr. Dujardin-Beaumetz has since experimented with a derivative of terpine, namely, terpinol, which is made by reacting on the former with sulphuric acid. Terpinol is described as being an oily substance, having an odor of jasmine, and being but little soluble in water. Dr. Dujardin-Beaumetz prescribes it in the form of pills as follows: Terpinol, benzoate of soda, of each sixteen grains; powdered sugar, q. s.; to be divided into ten pills, of which as many as ten can be administered daily. Terpinol is eliminated almost exclusively by the air-passages, and gives to the breath a strong odor of jasmine. It exercises its action principally on the bronchial secretions, which it rapidly fluidifies.

Diaphoretic Treatment of Nephritis.

N. Hess (*Vratch*) having made a number of observations on the treatment of nephritic patients by wet packs, hot baths supplemented by wrapping in blankets, and hot-air baths, draws the following conclusions:

1. The least rise of temperature occurs with packs, the greatest with hot-baths.

2. While the temperature is found to sink still still further twenty minutes after the pack, it remains at the same height for an hour after both the other methods of treatment.

3. After water baths the temperature regains its original height more slowly than after air baths.

4. During the pack the pulse becomes slower; during hot water and air baths, on the contrary, it is quickened for an hour afterwards.

5. Under the influence of the pack, respiration is moderately quickened; during both water and air baths it is still more quickened, but subsequently returns to its normal rate more rapidly than after the pack.

6. The most powerful sudorific effects are produced by hot baths, the least powerful by packing.

7. Though the baths are more stimulating, packing soothes the action of the nervous system, brings the patients on better, and produces a subjective feeling of improvement afterwards.

Sterility Occasioned by the Vaginal Secretion.

Dr. Jung, of Vienna (*Wien. Med. Presse*, xxiv., p. 1132), reported the case of a woman æt. 32, otherwise quite healthy, who, during fourteen years the wife of an officer, had remained barren. Menstruation always regular. She had been treated by gynecologists for her sterility by incision of the os uteri, and cauterization of the cervical canal, without success. Examination showed the cervical canal to be open, also no dilatation of the urethra. On a microscopic examination of the spermatozoids three or four hours after cohabitation, they were found to have no movement. On further examination, it was found that the movement was not lost at the time of the ejaculation, but occurred only after the action of the vaginal secretion had commenced. Hip-baths with astringent injections were ordered. After three months the woman found herself pregnant, and after a normal pregnancy gave birth to a healthy boy.

Indurated Chancre of the Eyelid.

Dr. Moty (*Gaz. des Hopitaux*, 128), a soldier, was received into the hospital with a double-sided conjunctivitis. The internal angle of the upper eyelid was swollen. Suitable treatment, cold applications and weak solutions of argenti nitratis, decreased the general tenderness, and the seropurulent exudation became less. In the mean-

time the place on the lid became harder, and an ulcer formed in the connective tissue in the neighborhood of the tear-ducts. This was accompanied by a heavy penetrating pain and light fever. After two or three weeks a swelling formed under the skin in the left temporal region. This was round and flat, hard, painful on pressure, and about the size of a hazelnut. This appeared to be grown fast to the periosteum of the skull. As there was no doubt left as to the diagnosis, the patient was placed under the influence of mercury, then of iodide. The recovery took place after about nine weeks. Concerning the manner of infection nothing is said.

Fistulous Communications Between the Intestines and the Female Genital Tract.

Since the application of plastic surgery to gynecological operations, the treatment of vesico-vaginal fistulæ is as well understood as are the etiology and symptomatology. The result, though, when contrasted with the old tedious plan of cauterization, is brilliant no less to the operator than to the unfortunate woman whose life is rendered miserable by such conditions.

Dr. H. D. Fry, of Washington, in *The American Journal of the Medical Sciences* for April, directs attention to less frequent forms of fistulæ that communicate with the genital canal, and records a very obscure and interesting case of intestino-vaginal fistula, which terminated favorably without surgical interference.

The Use of Cocaine During the Removal of a Needle from the Foot.

Dr. Samuel Nall publishes the following case in the *Brit. Med. Jour.*, June 27 :

A little girl happened to run a needle into the fore part of her heel ; the point broke off and lay embedded. By passing the blunt end of another needle along the track left by the broken one, the latter could be felt about a quarter of an inch from the surface. The pain, however, caused by the process of probing was so acute that he determined to try the effect of cocaine during extraction. He painted the surface near the puncture with a four per cent. solution of the hydrochlorate, and allowed some to trickle into the wound ; altogether, about eight or ten drops were used. In about half an hour's time, the part was so deadened that I was able to dilate the wound by means of a fine probe and forceps, and to extract the broken needle, without causing the slightest pain.

Treatment of Whooping-Cough.

Dr. W. Graeffner, of Breslau, has obtained remarkably good results in whooping-cough from cocaine, which he used in the form of the steam-atomizer, or of inhalations, or of the common cold atomizer. The solution employed by him is the following :

℞.	Cocain. muriat.,	gr. i–gr. iss.
	Aquæ destillat.,	f.℥iss.
	Pot. chlorat.,	gr. ix.
	Aq. amygdal. amar.,	♏x.

M. S.—Externally.

The applications were made twice daily, and rapidly brought about a cure. It proved also beneficial in cases of hysterical cough.

Correspondence.

Strychnia in Malarial Fevers.

Eds. Med. and Surg. Reporter:—

Never having seen an account of the use of strychnia in malarial fevers, I thought I would give my experience with it. Having tried quinine in heroic doses, and so often having a return of the disease, I concluded to experiment, and at last combined quinine and strychnia. This resulted admirably, and I continued to reduce the amount of quinine, until now I give no quinine at all in "chills and fever." I invariably give ℞. Liq. strychnos, ♏x., before each meal; and I have yet the first chill to see after the commencement of the remedy.

W. W. Reynolds, M. D.

Proctorville, Ohio.

News and Miscellany.

Notes of a Visit to Some of the Lying-in Hospitals in the North of Europe, and particularly on the Advantages of the Antiseptic System in Obstetric Practice.

These notes were read by Dr. Priestley, before the Obstetrical Society of London, July 1. The hospitals visited were those at Copenhagen, Helsingfors, and St. Petersburg. At Copenhagen, the new system began in 1870. In the Maternity Hospital, in the fifteen years from 1850 to 1864, the mortality was one in 24; between 1822 and 1843, it had been one in 19—that is, only slightly lower than the mortality in the Nightingale Charity of King's College Hospital, which compelled the author to close the ward. From 1865 to 1874, the mortality from puerperal fever was one in 51 ; from 1870 to 1874, it was one in 87, the improvement coinciding with increasing strictness in antiseptic precautions. The hospital was constructed in the most elaborate and expensive way to secure hygienic perfection, including ventilation, isolation of each part of the building (if desirable), and even a separate room for each patient. Moreover, the rooms were only used alternately, which was equivalent to halving the number of beds. The attendants were under strict rules of periodical purification, and were not allowed to pass di-

rectly from the convalescent to the lying-in wards. If a patient had been ill, the nurse was fumigated with sulphurous acid gas by an elaborate process. The same was used for disinfection of the rooms. The personal precautions included careful antiseptic hand-washing, soaking of catheters, etc. No sponges were used. The vagina was injected twice a day with carbolic acid lotion. The beds were of canvas, filled with chopped straw, which was destroyed after use. Each bed had its own basins, syringes, catheters, etc. The placentæ and dressings were burnt. On suspicion of infection, the patient was carefully isolated. The medical officers were not allowed to attend necropsies. The director lived in the hospital, of which he was absolute master. As in other hospitals, there was an undue proportion of difficult cases and of primiparæ, and the primiparæ had a large share in the mortality. The midwives of Denmark were compelled to use antiseptic precautions, and this had sensibly reduced the mortality. At Helsingfors, the hospital was arranged on the pavilion system, one block being devoted to diseases of women, including wards for operations and rooms for out-patients. The wards for lying-in cases contained about 42 beds; the beds were in the middle of the rooms. The mattresses were sacks of fresh rye-straw for the non-paying patients, and with horsehair or bark of the lime-tree for paying patients, all being cleaned, baked, and remade for each new patient. Some patients lay on the bare boards of the bottom of the bed, as was usual in Finland. Antiseptics were not as minutely carried out here. Midwives and nurses were made to wash their hands and arms with soap, and afterwards to rub them with hypochlorite of lime, before examinations. Abnormal cases were isolated. The medical officers were forbidden to attend necropsies, or to touch infectious wounds, without taking antiseptic precautions afterwards. Catheters were carbolized, and the wards periodically closed and cleaned. After labor, a single injection of carbolic acid was given, and often when specially indicated. The linen was simply washed; the blankets were fumigated by burning sulphur. Professor Pippingsköld trusted largely to the excellent hygiene of the hospital (built on a rock high above town), and to the clean habits of the people; but the external genitals were always washed before delivery, otherwise the object was to guard against external morbific influences, more minute care being thought unnecessary under the circumstances. Before the new maternity was opened in 1879, the total mortality averaged 1.83 per cent. From 1872 to 1884, the total mortality was one per cent. In the Grand Duchess Catharine Maternity Hospital, in St. Petersburg, there were arrangements for isolating the various parts. Scrupulous cleanliness, the disinfection of rooms, concrete floors draining into a central gully, and the careful use of antiseptics, were included in the system. In the last three years there had only been one death from puerperal fever, though six had occurred from other causes.

Dr. Matthews Duncan said that the subject of antiseptics in midwifery was the greatest in the whole obstetric department, but it got very little attention. The subject was greater than the prevention of epidemics, which came occasionally, while puerperal deaths were constantly occurring amongst the most valuable members of the community. The value of antiseptics in midwifery had only lately been estimated, because it was only lately that the profession had agreed as to the mortality of childbed. Some men had their thousands of cases without a death, and while he did not doubt their veracity, he did not accept their statements. No man could claim immunity from deformed pelves, placenta prævia, puerperal convulsions, phlegmasia dolens, puerperal inflammation, puerperal scarlatina, puerperal septicæmia, or puerperal insanity. Farr began by ridiculing the demonstrated puerperal mortality, but he eventually nearly accepted the received view—that about one in 120 died in childbed, or within a few weeks after delivery. In the history of the subject, all measures had failed to reduce mortality till antiseptics were introduced. Abroad, the great mass of women were attended by midwives, who were compelled by law to use antiseptics. In Great Britain most were attended by medical men, very few of whom used antiseptics. He hoped they would be universally adopted.

Dr. John Williams said that while it was not possible to abolish by antiseptics the effects of pregnancy and labor, the abolition of deaths from puerperal fever might be hoped for. The mortality of the St. Petersburg Hospital (one death from puerperal fever in three years) was a near approach to this. The results at Copenhagen and Helsingfors were little better than those in the Rotunda of Dublin before antiseptics were used. In seven years of office, Dr. Collins admitted about 16,000 women, and had two epidemics of puerperal fever, in which about 80 died, and the total mortality was one per cent. Dr. Macon, the present master, admitted, during his first year of office, 1,090, and of these six died, two at least from other causes than septicæmia. This excellent result had been obtained by careful antiseptic precautions. Dr. McClintock calculated that a quarter of the deaths in childbed were not due to childbed. Taking the deaths in childbed at one per cent., the lowest mortality in childbed after the destruction of puerperal fever would be a quarter per cent., or 2.2 per 1,000; and the object should be to reduce the mortality to this level; this, he believed, might be attained by antiseptics. This was the object of Dr. Champneys and himself at the General Lying-in Hospital, but the object had not been attained. During the first four years there were 7 deaths in 1,174, or a little more than 0.5 per cent. During the first 12 or 18 months carbolic acid was used; during a second similar period, permanganate of potash; and, since May, 1884, corrosive sublimate. During the first two periods, there was a good deal of illness, though the mortality was low; since the use of corrosive sublimate was begun, there had been no deaths from puerperal fever, and almost an entire absence of morbility. The mortality mentioned was the total mortality for all cases which were not well at the time of their discharge from the hospital, and were admitted into St. George's Hospital, under Dr. Champneys, or into University College Hospital, under Dr. Williams; and the result was incorporated with the statistics of the General Lying-in Hospital.

Dr. Champneys said that the total mortality

from all causes in the General Lying-in Hospital in the last four years and a half, since Dr. Williams and he had had charge of it, was nine in 1,360, one in 151, or 0.66 per cent. The last two deaths were from phthisis, with which the patients were practically moribund on admission. These results were decidedly good at the present time, though it was hoped to improve them in the future. The greatest care was taken to follow up the cases; on discharge, each patient was furnished with a post-card directed to the hospital, on which she was requested to write her state and that of the infant about a month after her discharge, or six weeks from her confinement. No statistics of lying-in hospitals were trustworthy which did not give the total mortality from all causes, and which did not state that no patient was transferred to another hospital, or that, if transferred, her progress was ascertained. The statement that no deaths occurred from puerperal fever was worthless in the absence of the whole mortality; and, indeed, all cases dying after childbirth were presumably, or in the absence of distinct proof to the contrary, cases of puerperal fever, and such cases often gave unmistakable, though unexpected, evidence of septic processes after death. Thus the statement that, in the St. Petersburg Hospital, there had only been one death from puerperal fever in three years, while there had been six deaths from other causes, did not carry conviction. That was certainly a most unusual proportion. What were the causes of the other six deaths? The triumphs of antiseptics had been greatest in the most filthy localities; where cleanliness and general hygiene had been attended to, the benefit, though undoubted, was less striking. Antiseptic teaching should be as clear and as definite as possible; if details were unnecessarily multiplied, nurses, and even practitioners, were liable to confuse the essentials with non-essentials, and even to throw the whole thing overboard. He found no difficulty in carrying out the same details in private as in hospital practice. The all-important thing was scrupulous antiseptic cleanliness of the hands. On this he insisted, on the part of nurses as well as on his own; and inspection of the nails and skin of the hands of nurses was important on this account.

Dr. West thought that the teachers of midwifery, or, better still, the Obstetrical Society, should pronounce definitely as to what was essential in antiseptic treatment. In Vienna, frequent vaginal washing and the introduction of iodoform into the uterine cavity, formed part of the system. Women would, he thought, be apt to dislike this interference, and it would also suggest to them the great danger which there must be to necessitate it.

Dr. Playfair was sure that, in private, not one man in a hundred used antiseptics in any thorough way. There were not the difficulties which Dr. West had imagined, and, in his own practice, antiseptics were as rigidly enforced as possible. Absolute surgical asepticism was, of course, impossible. He now supplied his nurses with antiseptic rules printed on a card, the chief rules being that the nurse should never touch the neighborhood of the genitals without careful antiseptic washing of the hands. The same precaution was taken with regard to all sponges, catheters, etc. Corrosive sublimate was preferred to carbolic acid. These rules were even more important for nurses and midwives, who often touched the genitals, than for medical men, who, as a rule, only did so during labor. Nurses were apt to be careless of details and of cleanliness, and the result was visited on the medical man. He hoped that antiseptics would soon be the routine practice, and he was sure the result would be most satisfactory.

Dr. Gibbons remarked on the common practice of pouring a few drops of antiseptic solution into an unmeasured quantity of water, which was useless. He asked Sir Joseph Lister what strength of carbolized vaseline should be used.

Dr. Murphy (Sunderland) regretted that the discussion had not included the details of the antiseptic treatment recommended. He asked the opinion of the Society as to the justifiability of attending a case of labor shortly after having examined a case of puerperal fever in consultation. The text-books said that practice must be given up for several months. Dr. Murphy thought that change of clothes and a warm carbolic bath, one in 100 for half an hour, gave sufficient security.

Dr. Braxton Hicks agreed with Dr. Matthews Duncan as to the value of antiseptics in midwifery, but not as to his estimate of puerperal mortality. He had, in ten years of early practice, 800 to 1,000 cases, and only one death, which was from puerperal fever. Morbility was as important as mortality. He referred to the injurious effects of human lochia inoculated into rabbits, as showing their poisonous character. The antiseptic vaseline or oil was of little importance compared with antiseptic cleanliness of the hands.

Dr. Harvey said that, in Calcutta, for many years, carbolized oil had been used for vaginal examinations, and that vaginal injections of carbolic acid or corrosive sublimate were used if any fœtor was noticed in the discharges. When there was pyrexia besides, the uterus was washed out. Good had resulted, but the mortality in Calcutta would always be high, as patients were often admitted after many hours of labor, and after the the establishment of septicæmia.

Dr. Priestley, in reply, congratulated Dr. Williams and Dr. Champneys on the results obtained by them, and said that he was informed by Dr. Grigg that, of 1,100 deliveries in Queen Charlotte's Hospital, between February 14, 1884, and July 1, 1885, there had only been one death, and that was from puerperal convulsions. He agreed with Dr. West as to the desirability of defining what amount of antiseptics were necessary, and he doubted if autogenetic infection existed. Antiseptic cleanliness of all things touching the genitals was all-important, but vaginal injections had better be retained meanwhile.

Manslaughter by a Midwife.

The necessity for warning the public against entrusting their lives to ignorant midwives was never better demonstrated than in the following occurrence which which we find recorded in the *Lancet*, July 11, 1885. It seems that a midwife, reported as reading and writing imperfectly, was lately charged with manslaughter. The prisoner was called in to attend a patient early in the morning of June 16. She had already attended her in one of her three previous confinements.

Finding a cross-birth, she pulled on the arm, and about two p. m. pulled it off, wrapped it in a cloth, and gave it to a little girl to put in a box. About 4:15 the husband came in, and asked the midwife if he should send for the doctor. She replied, "There was no need; it would have its time." Later, she seems to have told the little girl to get any doctor she could. About six p. m. the husband returned, and fetched a doctor, who found a broken bone protruding and the child undelivered. In reply to his question to the nurse as to what she had been doing, she said, "Oh, nothing; the arm came down in the afternoon." About nine p. m., a neighbor found the midwife administering brandy and water to the corpse. A post-mortem examination revealed the uterus ruptured. The doctor gave it as his opinion that the rupture was due to the violence used in tearing off the arm. After a strong appeal by the counsel for the defense, the jury found the prisoner guilty, and the judge sentenced her to a month's imprisonment without hard labor. The case is a most pitiful one, and on reading it (says the *Lancet*), feelings of indignation, depression, and almost despair, follow each other in rapid succession. For such ignorance, what is to be said? For the refusal to call in help, what punishment is sufficient? But for such a termination to a long life, spent, for all we know, respectably, soberly, and honestly, . . . ! Does not the blood of such people as this poor man's wife lie on the heads of those who neglect the great question of the education and registration of midwives? Is each successive government to be allowed to be content with the excuse furnished by the urgency of some measure required by the interests of a party? Are the lives of the poor matters of such utter indifference to politicians? A distinguished French teacher was in the habit of impressing on his class the danger of pulling on the arm in a shoulder presentation by relating a case in which a medical man had done so and had torn the arm off, the child being born alive and surviving. When he grew up, he brought an action against the doctor, and got 4,000 francs damages. "Never shake hands with a fœtus," said the teacher; "remember that that hand, so small, so silent, cries to you in a voice of thunder: '*Je vous demande quatre mille francs d'amende!*'"

Drugs Deficient in Strength.

Drs. Henry Leffman and Chas. M. Cresson have been purchasing various drugs from different stores in this city, and subjecting them to examination, with the view of testing their efficiency and strength. From a preliminary report made to the health officer, we learn that a variety of drugs sold in this city are deficient in strength. An analysis of samples of laudanum showed that it possessed only half the strength laid down as the standard in the United States Pharmacopœia.

Samples of tincture of iodine were found to contain only two per cent. of iodine, though the tincture should contain eight per cent. The proportion of iodine in other samples varied from two per cent. up to the regular standard. The standard quantity of mercury in mercurial ointment is fifty per cent., but in samples analyzed the percentage of mercury was as low as thirty.

Several samples of articles sold as disinfectants were analyzed, and some of them were found to be of little or no value for the purpose they were sold for. Samples of what was represented to be crude carbolic acid contained only about ten per cent. of that acid. Professor Leffman remarks, however, that "crude carbolic acid" is a very indefinite term, and there is no rule laid down as to the amount of the acid it shall contain, but people would expect to get at least fifty per cent. Some of the samples consisted of tar oils, containing slight quantities of carbolic acid, but they would be of no value as disinfectants.

Chlorine combinations sold as disinfectants were also found to be very deficient, some of the samples containing only one-half of one per cent. of chlorine, or but one fourth of what they should have contained.

Professor Leffman says that a sufficient number of samples has not been analyzed to warrant definite statements concerning the extent of the manufacture and sale of adulterated or defectively manufactured drugs. He would not apply the term "adulterated" to the drugs analyzed, but would call them defectively manufactured drugs. He says that it is probable that some of the samples which he and Dr. Cresson found to be below the present standard of the pharmacopœia probably reach or approach the standards of old editions of that work.

Dr. Leffman says that investigations in other cities have shown very extensive adul eration of drugs.

The Relations of the Catholic Surgeon to Craniotomy.

The *Detroit Lancet* (July, 1885,) says editorially:

"It is said that the Archbishop of Lyons, France, got the idea that the professors of his city were teaching and practicing some things which the church should not allow, especially in the matter of craniotomy. He argued that as life was ro be taken, the church must decide in the matter, tather than the doctors. Hence he submitted the question to the Holy Roman Inquisition in the following terms (*St. Louis Med. Jour.*): 'Is it lawful to teach the operation of craniotomy, when by its performance the mother's life may be saved and the child's destroyed, but when it is not performed both mother and child must perish?' The answer was returned from the Holy Father, and his advisors or associates, that the 'operation for craniotomy could not be lawfully taught.' It would seem from this that hereafter no Catholic surgeon could perform craniotomy without being liable to the displeasure of the church.

"A late French journal gives the history of two cases of uncontrollable vomiting of pregnancy, which were both allowed to continue till death relieved the sufferers. The physician reporting exclaims: 'O, what am I to do? On the one hand a poor woman implores me to save her, and on the other the priest says, "Thou shalt not kill." Doubt overcomes me, and my patient dies.'

"From time immemorial the Cæsarian section has been a favorite operation in Catholic countries, for doubtless the same reason that forbids the craniotomy.

"In this case, which speaks, the voice of God,

science, or the priest? We doubt whether there be a Catholic surgeon in America that would let a woman die when he was convinced that the operation of craniotomy would save her life. If he would, would he not be accessory to her death?"

Dr. Ferran's Inoculations.

The Paris correspondent of a foreign exchange tells us that Dr. Ferran has sent another letter to the Académie des Sciences. He protests against the statement that he wishes to keep his method a secret. Dr. Ferran proposes to go to Paris, and make inoculations in the presence of the Academicians. M. Bouley regrets that Dr. Ferran did not profit by the presence of the French Commission at Valencia to prepare his cultivation fluid under their inspection, and to make inoculations with it. M. Paul Bert suggests that, as Paris is free from cholera, and, therefore, cholera inoculations are unnecessary, Dr. Ferran should be asked to send over some of his inoculation fluid, in order to submit it to an accurate scientific examination. M. Brouardel, in his report concerning the Cholera Commission sent to Valencia, states that Dr. Ferran refused to indicate his method for attenuating the virus, nor would he give any of the fluid, although he said he could make two cubic metrès of it a day. The statistics published are not unfavorable evidence of the good effect of Dr. Ferran's inoculations; but the alcaldies of the different towns, and the provincial magistrates, declare that Spanish statistics are not reliable.

Alcoholic Consumption in Belgium.

Belgium, according to the London *Times*, affords incontestably the worst statistics in regard to the consumption of alcoholic liquors. In less than half a century the use of spirituous liquors has more than trebled itself in that country, while the population has only advanced from 3,500,000 to 5,500,000. The use of spirits increased 66 per cent. between 1851 and 1881, and of beer increased during the same period 15.75 per cent. The consumption of spirits, wine and beer for 1881, amounted in value to 475,000,000f. Although the country is so small, it contained in 1880 no fewer than 125,000 places devoted to the sale of intoxicating liquors. There was a public house on the average for every 12 or 13 grown-up males. The suicides rose from 54 per 1,000,000 inhabitants in 1848 to 80 in 1880. The lunatics advanced from 720 per 1,000,000 inhabitants in 1846 to 1470 in 1881. The Inspector-General of Belgian Prisons reports that four-fifths of the crime and social misery during the last quarter of a century has been directly attributable to intemperance.

An Enormous Calculus.

Professor Humphry writes to one of our foreign exchanges that there is now in the Pathological Museum of the University of Cambridge, a stone that weighed when removed 33 ounces, 3 drachms and 36 grains, troy weight. The patient was an old woman, who had experienced no inconvenience from the presence of the stone, until on one occasion she took a long horseback ride, when she was suddenly seized with violent pains. Thereafter she could never make water, unless the stone was first moved, and she continued in great agony until she died. The stone was removed post-mortem. The nucleus is lithic; to this succeeds a considerable portion of the oxalate of lime variety; this is followed by layers of the triple crystals, covered by a thick coating of lithic, which is occasionally broken by a layer of the triple crystals, and the external surface is principally composed of the fusible calculus.

The Traction Conduits as Nuisances.

It has been repeatedly hinted that the conduits of the Traction Company were likely to prove prejudicial to health in so far as owing to the opening for the grip, they are really open sewers. We now note that at a recent meeting of the Board of Health a letter was read from Dr. P. N. K. Schwenk with reference to the conduit of the Union line of cars, on Spring Garden street, between Ninth and Seventh streets. This, he said, was "filled to within three inches of the surface with a semi-fluid offensive mass of filth." He regarded this as an "infection centre," and a nuisance detrimental to health. The matter was referred to the Medical Inspector to examine and report.

An Out-Door People.

To read of the "camps" this summer, religious and military, within less than a hundred miles of Philadelphia, is sufficient to show that as many thousands of people, now-a-days, as there were dozens a generation ago, get their ten days of open air in that way. The subject may differ, but the object is pretty much the same, a holiday of enthusiastic pursuits. The military encampments by the sea-shore are fortunate in their selection of places. They are not compelled to undergo the camp commissariat, and they have the beaches for parade-ground, if they choose to take them. Whether the bathing makes better soldiers of them or not, it certainly must add very much to the comfort and cleanliness of camp life.

The Bridgeport Epidemic.

It is reported under date of August 16, that the epidemic in the town of Bridgeport, Fayette county, Pa., is growing worse. The disease is dysenteric in nature, and is attributed to the dual circumstances of the filthy, unsanitary condition of the town, and the depraved physical condition of the people, due to the scarcity of good and wholesome food, owing to the hard times and absence of work. Dr. A. W. Howell, the only physician in the town, died recently of the disease, while Drs. Wakefield, Marsh, and Watson, of Mount Pleasant, are kept busy night and day.

The Lifeless Paris Morgue.

The morgue in Paris is too lifeless, so to speak, to suit the *Evenement*, which complains that it has nothing Parisian about it, that it wants gayety, and is generally unworthy of a city where the cemeteries are gardens, where funerals are festivals, where criminal courts are places of public entertainment, where executions are spectacles, and where a siege is the excuse for a carnival. An Irishman would probably say that the way to enliven the morgue is to put some life into it.

A Clever Impostor.

A Russian, who has been going about New Haven, Conn., soliciting alms on the strength of a badly swollen hand, which he told people was caused by rheumatism, was arrested a few days ago. At the hearing it was developed that the culprit was not afflicted with rheumatism at all, but had tied tightly a bandage around his arm, near the elbow, so as to make the blood settle in his hand and produce the swelling. A German present at the hearing said it was a regular trick of ordinary beggars in European cities. The prisoner was sent to jail for sixty days.

Items.

—A congress of Russian alienist physicians will be held in Moscow in September.

—The *Revista de Pharmacia e Drogaria* of Rio de Janeiro states that a free school of pharmacy has been founded by the Pharmaceutical Institute of that city, and is to be maintained at its expense.

—Dr. J. C. Neal, of Archer, Fla., writes: "In all the cases of exophthalmic goitre I have seen for several years, the patients, mostly female, have had auburn hair. Is this a coincidence or not? Have others noticed such cases?"

—M. Magnan cites a number of cases of madness among anti-vivisectionists. One woman first renounced animal food, then took in all stray dogs, and finally went round to the butchers, begging them not to slaughter any more cattle. She became finally mad.

—Professor Billroth, of Vienna, has lately received from the King of Portugal the large gold collar and star of the order of St. James, for skill and knowledge. The decoration is one which is very rarely bestowed. Some time ago, Dr. Billroth was called to the Portugese Court to consult in a surgical case.

—A. Häcker mentions in the *Vratch* some cases of foreign bodies in the air-passages. In one of them the patient, a child of five years of age, had been given a powerful emetic by a "feldsher" (a hospital sergeant), and when Dr. Häcker arrived, the child was almost moribund. He thinks that, as a rule, emetics do no good in these cases, and may produce serious mischief.

—In spite of severe sentences, the disgusting offence of biting still continues to be frequently practiced in Liverpool. In two recent cases the victims were city constables, and in each case the assailant was awarded three months' imprisonment with hard labor. In a recent case, the prisoner, a young woman, was committed to the sessions for trial for biting severely another woman, whom she also dragged to the ground and beat.

—The *London Med. Times* says that Professor Gustavus Jäger, well known in Europe as the apostle of woolen clothing, lately patented a pill, which contained, as he said, a distillation of the liquid which exists in human hair, and advertised his pill in a learned-looking pamphlet as a sovereign cure for many internal disorders. The Austrian Minister of the Interior was inquisitive enough to have these pills analyzed, and finding them to contain nothing but sugar of milk, has forbidden them to be sold.

—The Boston *Traveller* tells the following on the authority of a truth-telling auctioneer of that city: "A year or more ago, the auctioneer had for sale a lot of homœopathic medicines. All these medicines were dumped into one pile, and disposed of in one lot, there being various kinds of medicines in the mass. A boarding-house keeper bought the lot, and some days after the purchase, the auctioneer asked her, 'What did you do with that homœopathic medicine, Mrs. ——?' She replied, 'I thought I could use it, and it was cheap, and so I crushed it under the roller and then filled my sugar-bowls with it. The boarders seemed to like it, and especially when powdered over pies.'"

—Dr. G. Krosz writes to the *Deutsch Med. Zeit.*, that the removal of a plaster-of-Paris dressing is greatly facilitated by first scraping a groove with a knife, and then dropping along it a solution of caustic soda. In a few minutes the plaster becomes pulpy along this line, and the bandage can then easily be cut through. If two lateral grooves be made, instead of one, a lid can be cut out of the bandage, the leg can be lifted up for the necessary inspection and returned, the lid being reapplied and retained with a roller bandage. In this way the plaster dressing is not cracked, and the limb is not jolted in the effort to remove the bandage. By this method, also, it is a very easy matter to cut any fenestra that may be needed.

MARRIAGES.

ARNOLD—BRUMMELL.—August 5, 1885, at Seabright, N. J., by Rev. Charles Searles, Dr. Thomas B. Arnold, of Babylon, L. I., and Miss Adelaide Viola Brummell, of New York.

DOTY—BRUCE.—August 3, 1885, in New York, at the residence of the bride's parents, by Rev. D. Parker Morgan, Dr. Alvah Hunt Doty and Mary Thornton, daughter of Col. Sanders D. Bruce, all of New York.

HUSTEAD—KELLY.—June 25, 1885, in Wheeling, West Va., at the residence of the bride's parents, by Rev. D. A. Cunningham, D. D., Ashbel F. Hustead, M. D., and Miss Alice V. Kelly.

LEAVITT—KACHLINE.—June 23, 1885, by Rev. W. H. Filson, John F. Leavitt, M. D., and Miss Clara Kachline, all of Frenchtown, N. J

NIEL—WEEKS.—July 22, 1885, by Rev. John G. Oakley, Dr. James Niel, Jr., and Miss Georgina Weeks, daughter of Mrs. Margaret Kidd, all of New York city.

SAILER—DUFFY.—July 29, 1885, in New York, Dr. Zachary T. Sailer and Miss Rose Duffy, both of New York.

DEATHS.

ALEXANDER.—July 29, 1885, in Evansville, Ohio, Dr. Wm. Alexander, of apoplexy.

CORSE.—August 10, 1885, James M. Corse, M. D., in this city, aged 73 years.

FINLEY.—August 4, 1885, at Fort Concho, Texas, Dr. Samuel Moore Finley, Acting Assistant Surgeon U. S. A., oldest son of the late Surgeon-General Clement A. Finley, U. S. A.

TULLY.—July 30, 1885, suddenly, in New York city, Marcus C. Tully, M. D., in the 67th year of his age.

UPDEGRAFF.—August 3, 1885, in Elmira, N. Y., Dr Thaddeus S. Updegraff, chief of the staff of the Surgical Institute, of Bright's disease, aged 46 years.

He was an eminent microscopist, and two years ago was made a Fellow of the Royal Microscopical Society of England.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

FRANZ STAFFEL'S APPARATUS FOR SCOLIOSIS.

BY A. B. HIRSH, M. D.,
Chief of Orthopædic Clinic, Philadelphia Polyclinic.

Dr. Staffel is Interne of a specialist orthopædic institution at Wiesbaden, and, in the *Berliner Klinische Wochenschrift*, of June 15, writes a valuable and interesting though lengthy article upon "New Aids in the Therapy of Scoliosis," which I have translated and condensed for the REPORTER.

He reviews the arguments which have within the past few years been advanced for and against the Sayre jacket; concludes that the jacket serves its purpose well on general principles, but that individual cases require special braces in *combination* with the sustaining corset, whether the latter be made of plaster, soluble glass, felt, leather, or any other material, and quotes Beely to the effect that the Sayre jacket may well be applied in clinics and hospital practice, because of economy in time and cost, but this necessity does not exist in private practice.

Although many varieties of braces already present themselves for professional favor, new models are being continually brought forward, some defect existing in each of the earlier ones.

The question is not here discussed of the actual *curative* power of these apparatuses. Suffice it to say that, in the incipient stages of scoliosis, such appliances are absolutely required to improve the deformity or, at least, to stop its further progress. For the latter purpose, the brace is purely a supporting one, and its value none can here dispute.

The extent to which the deformity can be reduced depends largely on the opposing amount of rigidity of the tissues uniting the bones involved. Orthopædic gymnastics here add their quota in accomplishing the desired object. So, also, will each apparatus suffice to fix the replaced spine into but the one position which corresponds to its own shape.

Nearly all braces for scoliosis are formed of a padded band of sheet-steel which fastens around the pelvis; the pelvis is thus the fixed point upon which plays the movable upper part of the corset. Furthermore, by adding certain fixtures (Stützvorrichtungen), some weight of the upper part of the trunk can be transferred directly from the spinal column to the pelvis. The pelvic band obtains a firm support about the trochanters, which grip can be increased by means of bent strips of metal, etc., passing diagonally over the iliac crests. The shoulder-band is frequently utilized by which to apply the support or counter-pressure; yet this is an uncertain point of application as, especially in the upright position, the shoulders are very evidently not fixed points.

Most of the braces in ordinary use are intended for the typical cases of scoliosis—the lumbar spine bowing to the left and the dorsal to the right—and work by means of pads or pad-like bandages, together with or minus axillary crutches. The mode of replacing such a doubly curved deformity, would be about as follows: Standing behind our patient, the palm of one's right hand, when applied to the back of the right side of the thorax, pushes the latter towards the left into its normal position, and rotates the twisted spinal column into its proper vertical

axis. The results of the forces applied are a *diagonal* and a *direct* (straight) pressure. When the individual is slim, and the chest yields easily, it will suffice to simply bear forward without rotating it; and to prevent rotation here, counter-pressure is made by the left hand at a point more forward upon the front and left side of the chest.

In practice, where the rotatory and oblique movements are desired together, the bands are exchanged for a compress or pad upon the right side for the oblique pressure, while, at the same time, another pad upon the front and left side of the thorax affords the direct counter-pressure. The action of such an anterior pad is uncertain as its application is attended with difficulty. It is thus usually avoided, and, consequently, a rotatory action of the apparatus not expected.

The nearer the dorsal pad to the pelvis, so much the more is the whole chest pushed forward, and so much easier can we avoid using the anterior counter-pad to rotate the spine as desired. The higher lies the hindmost pad from the pelvis, so much more does the converse hold true.

But, when the right-sided dorsal pad is employed, the lumbar pad upon the left side (used by many orthopædists) serves no purpose, and is in most cases, therefore, superfluous. Where, as usual, the dorsal curve is the main one, the lumbar curve is too short to afford support to a pad other than would merely steady the whole apparatus. Should the lumbar curve, however, be greatest, then, of course, the lumbar pad would be applicable; the reason is that the apex of the dorsal curve in this instance lies so high up in the axilla that the dorsal pad would have to be applied necessarily almost upon the shoulder-blade, and its value in that situation would be questionable. Extra pads, of course, render the brace more complicated, heavier, and costlier.

Even where the rotating and reducing action of the posterior dorsal pad cannot be fully expected, there remains the direct portion of its pressure, which is greatly to be desired. On the one hand, where simply forward pressure is made, there is danger that the chest wall, already greatly deformed, will be still further bent together; and, on the other, if by such portion of this compress it is not firmly pressed, there yet remains (by means of an extra attachment) a proper direct force. *Oblique* pressure forces the pad firmly against the projecting ribs.

The only practical appliance for scoliosis whose pads allow of considerable pressure—either direct or diagonal—is the one devised by Nyrop; but, good as is its design, it has its weak points, such as a rather too heavy application, uncertain regulation of pressure by the pads, etc. Other orthopædists have tried to remedy some of these defects.

Accordingly, having in view the scoliosis apparatus of Eulenberg and Langenbeck, I have had constructed an appliance which combines the padded corset with an arrangement for diagonal pressure, which has given me highly satisfactory results. The essential difference between the original apparatus and my own lies in the situation of the endless screw which controls the mechanism of the pads—lying, in the former, parallel to the band about the pelvis and, therefore, exerting a merely forward pressure. This I have placed *vertically* to the pelvic band, at a point half way around to the side of the body. This allows of increasing at pleasure either the straight or the merely forward pressure, *i. e.*, it pushes the cuirass either to the middle of the back or over to the side.

The basis of this apparatus (figure shown) consists of a sheet-steel pelvic band shaped exactly to fit the body. Now, when this girdle, as also the other metallic parts, are only roughly finished, I apply it so as to see that every point fits and lies correctly, and then carefully direct at what precise point upon the band the screw arrangement shall be fixed. The pelvic band is strengthened at this point by having riveted upon it a strip of iron some fifteen centimetres long, so as to give a

firm base for the superimposed mechanism. The thread of the endless screw forces upwards the iron bands which embrace the trunk, and to these bands is affixed the pad already spoken of. The screw arrangement is controlled by a key.

A crutch for the axilla is attached to the left side of the pelvic band—partly to secure a symmetrical position of the shoulders, and also to somewhat relieve the spinal column. A similar crutch upon the right side is superfluous, because the dorsal pad serves a like purpose both for the thorax and the axilla too.

A strong corset, which laces up in front, is sewed upon this frame, and the pad is next sewed fast at the place exactly required. On the left side, as also upon the right side, beneath the pad, are whalebones or steel ribs inserted. Shoulder bands are employed. The left one, applied loosely, passes from near the inner and upper angle of the shoulder-blade, outwards across the shoulder, and fastens on a button upon the crutch tip. The right band, on the contrary, crosses the shoulder from the front, is drawn tightly obliquely across the back over the deformity, and fastened into a hook upon the left side. By this means the right shoulder is drawn backwards and outwards and the ribs sustained in a fixed position. It would be difficult to retain this pad in place were these bands wanting.

For the other forms of scoliosis, modifications of this apparatus would be necessary, and would readily suggest themselves.

In order that the pad should fit hermetically to the desired spot, it is my custom always to personally make a model for it beforehand. Taking a piece of sheet-lead of about the required size and shape, I press it firmly and evenly with the palm of the hand over the surface where the future pad shall lie. A solution of plaster-of-Paris, when poured into this mould and allowed to harden, serves as a block over which the final pad of steel plate or of brass may be finished.

Upon turning the screw the reacting force of the pad naturally strains the pelvic band into a position, having the left side directed forwards and the right side backwards (the upper edge away from the trunk and the lower border bent towards it); but, by means of carefully shaping the cuirass to the body, and by the supplementary band upon the pelvic ring already mentioned, we are enabled to overcome this tendency to bowing of of the band. Then, as a result of this oblique displacement, there is generally some irritation from the pressure upon one or both anterior-superior spines of the ilium; these points usually lose their irritability after a time, or it may even be necessary to interpose layers of wadding, etc. Otherwise, no trouble is caused by the apparatus; especially do we have no trouble from the pad in the back, as it is applied so hermetically to so large a surface.

As conclusions, this apparatus suggests the following:

1. Its simplicity, therefore corresponding lightness and cheapness.

2. It produces a regulated pressure in the necessary diagonal line of leverage, which may be modified to suit.

3. It is not bulky, therefore can be worn beneath the clothes.

4. Both shoulders remain free from all untoward pressure.

The qualities required for all scoliosis apparatus is likewise here demanded. So as to attain definite results (supposing no very skilled instrument maker to be near), the attending surgeon must first fit the brace in the roughly-modeled state, so that all its parts acquire their exact shapes and positions. The apparatus must always afterwards be carefully reapplied, and the surgeon cannot too often change it to suit the requirements of the case in point. He should possess, on this account, a knowledge of mechanics as well as their practical application, along with boundless perseverance. But these qualities wanting, nothing can be expected from any treatment of scoliotic patients.

In treating curvature of the lower half of the spinal column, which is accompanied by but little or no compensatory curvature on the opposite side above, I have obtained the best results from the application of ribbed corsets; and, although ribbed cuirasses are by no means a novelty, yet in the mode employed by myself they are scarcely or not at all known. I designate them as *flexible ribbed corsets*.

This deformity presents itself chiefly with the convexity toward the left side, the so-called C-shaped scoliosis, where the prominence lies deeply. It is always my purpose here, by means of these ribs, to hold in a fixed position the completely replaced trunk, and its vertical contour is thereby obtained.

The patient's back being turned towards me, his knees and heels together, I order him to draw in his convex (let us say to the left) side until he has, as far as he is able, produced a perfect symmetry of the sides. Then, taking a strip of sheet-lead about 2 centimetres broad, 2 millimetres thick, and of the length to be covered, I lay it vertically against the trunk, beginning about the

middle of the scapula, and ending just above the trochanters, and press it firmly into place. This leaden model is twice outlined by lead-pencil upon a sheet of paper, if the patient be a young child, and three copies made if older or more fully grown. The second—*i. e.*, third—measure is taken in the line of the axilla, and reaches from the axilla to just above the trochanters. Steel ribs from 1½ to 2 centimetres broad, and from 1 to 1½ millimetres thick, are now made over these outlines. These ribs of sheet steel will "feather" somewhat when hardened, bending sufficiently under moderate force to be shaped to fit.

I thus have made a strong, exact-fitting corset, closed behind and lacing up in front, which reaches far down below, and covers two-thirds of the scapula above. When finished, it is put on and fastened everywhere; then the steel ribs which have previously been lacquered and covered with strips of linen, are slipped up between corset and undershirt to their proper situations. Their measure is here again taken, for, if rightly placed, the outlines of the ribs stand in relief, and can be outlined by lead-pencil. Over these pencil-marks strips of the corset fabric are sewed tightly, and the ribs slipped into the gutters thus made, after which the minor details can be finished. Merely light whalebones or steel ribs suffice for the opposite side. Shoulder-straps go from behind the shoulder-blades, over the corresponding shoulders, through the axillæ, and cross upon the back, fastening by a hook upon the outer opposite side; these insure firmness for the corset, and especially the steel ribs. The scoliotic individual is forced into an erect posture while wearing this corset, always provided the ribs can be shaped to the fully reduced deformity of the body, and the ribs themselves seem to cause little or no irritation at all. About from two to three months must be allowed in a growing patient before withdrawing the ribs, obtaining the new shape, properly changing them, and, finally, sewing into the proper sleeves these re-formed steel plates.

Were this corset to find its application in simply mobile, deeply-seated lateral curvatures, I have nevertheless learned to regard it as the simplest, but most practical, curative mode yet offered, and, being simple and ready at hand, can recommend it to be employed.

The various orthopædic gymnastics come into play here also (supplementing the action of the corset), and, by removing the obstacles to the correction of the deformity, make it so much easier to retain the trunk in its wished-for position.

EXTRA-UTERINE GESTATION—RETRO-UTERINE HÆMATOCELE—DEATH—AUTOPSY.*

BY ISAAC N. SNIVELY, M. D.,

Of Waynesboro, Pa.

GENTLEMEN: You will remember my reporting a very interesting case of retro-uterine hæmatocele to this society over ten years ago, which was afterwards published in vol. ix., folio 118, Transactions of the Medical Society of Pennsylvania, which happily terminated in recovery, and the lady is still enjoying excellent health, and has since given birth to several children. To-day I desire to report to this society my second case of this rare kind of pelvic tumor, produced from different causes, from which my patient speedily died.

Mrs. McP., aged 44 years, and the mother of five children, sent for me May 3, 1882, whom I found feverish and very feeble, complaining with uterine trouble, indigestion, and flatulency. She was placed upon careful general and local treatment.

May 9. I again saw her, and my former treatment was continued.

14th. A careful examination of the uterus revealed considerable hypertrophy of this organ.

22d. Dr. H. A. Bonbrake and I met at her house, and found her suffering very much from pain over her bladder and uterus, with considerable abdominal distension. External applications and morphia sulphas hypodermically gave her a comfortable night.

23d. We found her more comfortable, but there was some retention of urine, which was relieved by the catheter.

June 3. Our patient has been getting along more comfortably until to-day, when we were hurriedly summoned to find new symptoms presenting themselves. An examination per vagina revealed a large retro-uterine hæmatocele pressing upon the bladder and uterus, forcing these organs out of their normal position, and pressing with great force upon the bowel, making it impossible for her to have a natural evacuation. The urine was drawn. There was a good deal of tenderness over the bladder and kidneys. Pulse 100; temperature 98°; respirations 16. Tumor fluctuating, and temperature of the vagina and tissues adjacent to the tumor about normal. She menstruated two weeks ago.

4th. She had her bowels relieved by an enema, and her skin is soft and moist, her temperature

* Read before the Franklin County Medical Society.

normal, pulse 90, and respirations 16. Her urine dribbles away when not frequently drawn with a catheter.

5th, 8 a. m. Pulse 90, respirations 16. She had a more comfortable night. She is able again to void her urine. A small quantity of blood passes per vagina.

6th, 9 a. m. Temperature 102°, pulse 96, respirations 16½. Some epistaxis.

7th, 8 a. m. Temperature 98½°, pulse 120, respirations 16. Bowels relieved by an enema. Bloody discharge per vagina continues. Epistaxis again to-day.

8th. Temperature 99½°, pulse 110, respirations 16.

9th. This a. m., temperature 102°, pulse 122, respirations 17. Bloody discharge per vagina.

10th. This a. m., temperature 99°, pulse 120, respirations 16. Bowels moved by an enema.

11th, 10 a. m. Temperature normal, pulse 116, respirations 17. Anodynes are used at night. Skin moist, and she is able to void her urine. She is growing weaker. The tumor is diminishing in size, but is harder. The aqueous portion of the blood in the tumor is gradually absorbing. She is not suffering much, and seems cheerful.

13th. Temperature 99°, pulse 120, respirations 17. Bloody discharge per vagina continues.

14th. Temperature 99°, pulse 115, respirations 17.

16th. Temperature 98½°, pulse 110, respirations 17. Tumor smaller and patient cheerful.

18th. Temperature 98½°, pulse 108, respirations 17. Bowels well moved, and she passes urine without difficulty; little appetite; pain in legs, thighs, and back. She can now put on her stockings for the first time since her illness. Less distension.

21st. Temperature 99°, pulse 110, respirations 18.

23d, 9 a. m. Temperature 99°, pulse 130, respirations 20. At 2 p. m., mind wanders. At times does not know members of her own family. Had no opiates since the 21st. She is inclined to stupor. We fear septic poisoning. 11 p. m., temperature 99°, pulse 124, respirations 27.

24th, 4 a. m. Temperature 100°, pulse 130, respirations 26. Skin moist, and there is very little delirium. 10 a. m., temperature 100°, pulse 124, respirations 27. There is some blood passing from the bowels. 11 p. m., Dr. Bonbrake found rupture of the sac into the rectum. Temperature 102°, pulse 140.

25th, 9 a. m. Temperature 104½°, pulse 140, respirations 34. Blood continues to pass per rectum. The cyst seems to be gradually emptying. Some tenderness over abdomen. Sudden rise of temperature shows peritonitis developing. This inflammatory trouble and considerable loss of fresh blood will soon terminate the case.

26th, 5 a. m. Temperature 104°, pulse 150, respirations 35. 6¼ p. m., she died without a struggle.

27th. This a. m., 14 hours after death, Dr. J. D. Weddells, of Adams county, Pa., and I, made an autopsy. Upon opening the abdomen, we found general peritonitis, with extensive adhesions of the bladder, uterus, and bowels. The omentum was bound fast with strong adhesive bands. The bladder was firmly adherent anteriorly to the walls of the abdomen and posteriorly to the uterus. The uterus was very much hypertrophied, enlarged at least five times the size of a normal organ.

The omentum was highly inflamed—large quantities of coagulated blood filled Douglas' space. This *cul de-sac* contained a large cyst—the retro-uterine hæmatocele composed of fibrous tissue. We cut into the tumor and removed large quantities of grumous blood. In the centre of this grumous mass was found the fœtus, with placenta, etc., all complete. An opening communicated with the bowel, through which a large quantity of blood escaped the last few days of the patient's life. Another opening communicated with the pelvic cavity, a quantity of blood being found over the bowels. Kidneys and other organs healthy. This is the first case of extra-uterine gestation I have had the misfortune of meeting with in a practice of over twenty years.

Perhaps one of the saddest accidents which can possibly befall a woman is extra-uterine pregnancy. Fortunately this is of rare occurrence, but when it does happen the rule is that your patient dies.

As to the frequency of extra-uterine gestation, Bandl mentions that out of 60,000 gynecological and obstetrical cases received during seven years at the cliniques of Carl Braun, and Späth in Vienna, there were only five cases. As to the relative frequency of the various forms, tubal gestation is the most common—about two-thirds of all the recorded cases. Indeed, Lawson Tait, Surgeon to the Birmingham Hospital for Women, etc., and of high authority, maintains that every case of extra-uterine pregnancy is tubal in its origin, and that it may become intra-peritoneal or extra-peritoneal, just as the tube happens to burst; that the intra-peritoneal termination is, beyond all question, the more common and more

fatal; whilst the extra-peritoneal development of the ovum is very rare, less fatal, and, what is of more consequence, far more amenable to treatment. This rupture usually occurs between the second and third month.

Etiology.—The cause is thought to be some mechanical obstruction to the passage of the ovum through the Fallopian tube. Bandl explains the relatively greater frequency of extra-uterine gestation in older patients by the fact that catarrh of the tubes is more frequent in them. Polypi in the tube have been found as the cause of obstruction.

Diagnosis.—The diagnosis of extra-uterine gestation in its early stage is surrounded with difficulties, and we are seldom called upon to consider it until all hope of successful interference is over. I refer now to cases of tubal rupture.

Differential Diagnosis.—When the sac ruptures early, *differential diagnosis of hæmatocele*, due to this cause from that due to any other cause, is impossible without a post-mortem examination.

Before the rupture of the sac it must be differentiated from the following conditions:

1. Normal impregnated uterus.
2. Retroflexed gravid uterus.
3. Simple hæmatocele.
4. Ovarian tumor.
5. Fibroid, or fibro-cystic tumor.
6. Extensive pelvic inflammation.

Progress and Termination.—Over four-fifths of the cases end fatally. Kiwisch found the mortality 82.5 per cent. Hennig found a fatal result followed in 88 per cent., and death occurred most frequently at the second, third, or fourth month.

Treatment.—Four methods have been adopted:

1. Tapping the sac.
2. Tapping and injecting morphia or other narcotics.
3. Electricity.
4. Removal of the fœtus by abdominal section, or through the roof of the vagina.

PROSTATITIS; A DISEASE PECULIAR TO THE MALE SEX.*

BY G. W. GARRISON, M. D.,
Of Utica, Ohio.

It may be either acute or chronic, and a person so afflicted (chronically) may be subject to acute attacks, should the urine become in any way irritating to the bladder, as by decomposition in consequence of retention. We may be summoned at any moment to relieve a great sufferer. The period of life when this dyscrasia is most liable to occur is sixty years or upwards. The first evident admonition of the onset of this dreaded disease from which we may take warning of dangerous forebodings, is when we discover that favorite force by which we are enabled to evacuate our bladders by squirting the water from us a distance of fifteen to twenty feet, is on the wane, and as age creeps upon us, with its accompanying decrepitude, it is strikingly manifest to us the slowness in starting to urinate and the time required to complete the operation by a dribbling stream. When this condition of things overtakes us, we should be extremely careful to inquire into any and all prophylactic measures to prevent an acute attack of prostatitis, as a slow dribbling stream may be a symptom formative of congestion and hypertrophy, or still worse, prostatitis, as before indicated.

Etiology.—The most exciting cause is sitting on a cold stone, or passing cystic calculi, or decomposing urine retained in the bladder, etc. These are the honorable exciting causes; whilst gonorrhœal virus traversing up the urethra might be denominated the dishonorable exciting cause. Again, we find cases where our patient cannot give us any evident assignable cause, but seemingly a local hypertrophy of the gland, with considerable heat and congestion, will be recognized, accompanied with frequent desire to micturition.

Diagnosis.—In order to ascertain what is prostatitis, should we be called to the bedside of a man with certain symptoms, heretofore named, we must take all his symptoms—subjectively and objectively. First pass index finger up the rectum, and should you discover an enlarged prostate gland, with heat and *pain* on pressure, together with frequent desire to urinate, the diagnosis will be clearly made out as one of prostatitis.

Prognosis is favorable unless the difficulty should run into suppuration, followed by constitutional disturbance, such as chill and fever, night-sweats, and the sufferer a feeble old man, and the urine allowed to become decomposed by long retention, etc.

Anatomical Appearances.—The structure of a hypertrophied prostate gland, due to inflammatory engorgement, or otherwise, wherein suppuration does not ensue, is but a slight modification of that of the gland itself.

Treatment.—If non-specific—with no constitutional disturbances worth mentioning—local fomentations, with hot hops and a saline cathartic, followed by anodynes *pro re nata;* and a suppository of opium and belladonna in the rectum at night is all that will be required. As a drink,

* Read before Licking County, Ohio, Medical Society.

give warm mucilaginous lotions, and use the catheter whenever indicated. This, with fluid diet, will be all that is required; but should some specific virus, as gonorrhœal, be the exciting cause, your attention must be directed to the relief of that venereal complaint. In case suppuration occurs, you must boldly let the pus escape by using the bistoury, for if we wait for nature to effect an opening, the urine will follow the pus sinuses; then, of all sufferers, our patient will be the most miserable, and the cure will be entirely thwarted.

I would add, on closing, that these terrible sufferers require an abundance of attention in several particulars, viz., drawing the water regularly at stated intervals of eight to twelve hours, due watchful care of the gland for pus; testing the urine with litmus paper; if found other than neutral, you must resort to appropriate remedies to render the urine non-irritating, and by constantly watching in order to apprehend all side issues that will make your patient more miserable; then, in the event of the recovery of your case, everlasting praises will be heaped upon your name.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated meeting June 25, 1885, the president, E. O. Shakespeare, M. D., in the chair.

Dr. Wm. Osler exhibited for Dr. McLaren, of Paisley, Ontario, some specimens, which he had sent him, of

Hydatids Passed with the Urine,

with the following history, dated April 13, 1885. The patient, Geo. S., aged 58, an Englishman, resident of Ontario for thirty-five years, at present a farmer, but formerly a butcher for fifteen years. Always enjoyed good health until about four years ago, when he had a severe attack of nephritic colic on the right side, lasting only a short time and quickly relieved. Had no further trouble until two years afterwards, when a similar attack occurred, confining him to bed for several weeks; some days he was better, but always worse on exertion. After a period of improvement for several weeks, during which time he was able to attend to his farm duties, he felt pain and uneasiness over the right kidney, followed in a day or two by pain at the point of the penis, which continued for several hours, and was relieved by the passage of gelatinous-looking masses in the urine. These bodies—hydatid—he has continued to pass at intervals of from two to four weeks. The discharge is always preceded by an uncomfortable feeling of fulness in the region of the kidney and pain or uneasy sensations at the penis. No tumor has at any time been discovered in the neighborhood of the kidney. With the exception of these attacks of pain and distress in the urinary organs, prior to the discharge of the hydatids, he enjoys good health. He lost no weight; appetite good; bowels regular.

The specimens, which were given to me for examination by Dr. Palmer Howard, of Montreal, consisted of ten or a dozen hydatid cysts, ranging in size from a pea to a grape, and contained in a small quantity of urine. They were evidently the daughter-cysts of a larger one which was in communication with the urinary passages. Several of the cysts contained smaller ones (granddaughter-cysts). On examination of a drop of the urine in which they were, numerous hydatids and the characteristic hooklets could be seen.

Echinococcus of the kidney or urinary passages is very uncommon. Statistics show that the left organ is more frequently affected than the right. The points of interest in this case are: the long duration, the absence of evident tumor, and the excellent condition of the patient. Here is evidently a cyst of considerable size, possibly in the right kidney, and which bursts at times into the pelvis with the discharge of the hydatids.

In 1882 Dr. Osler had reviewed the literature of American cases of echinococcus disease, and had made inquiries of the curators of the principal museums, the result of which was the collection of sixty-one instances of the disease (*Amer. Jour. Med. Sciences*, 1882). In not one of these was the cyst in the kidney. Since that date six other cases have been reported by Carson (*St. Louis Courier*, 1884), cyst of liver; Schæffer (liver), Trans. Med. Soc. Penn., 1884; liver (liver and mesentery), *N. Y. Med. Jour.*, 1885; Helen, *New Eng. Med. Jour.*, 1883–4, cyst of liver, ruptured into intestine; Welsh, spleen, *Med. News*, 1884.

Dr. Morris Longstreth exhibited a series of six specimens of echinococci situated in various organs. Owing, however, to the notes not having been forwarded to the Recorder, no details can be given.

Dr. J. H. Musser presented the following specimens, the histories of which will be published elsewhere: Melanotic sarcoma, acute suppurative pancreatitis, thrombosis of portal vein, cirrhosis of liver, and syphilitic disease of the lung.

Dr. J. R. Mitchell presented a specimen of carcinoma of the peritoneum, liver, and pancreas. The details will be published at a future time.

Dr. C. B. Nancrede presented a specimen of suppurating hæmatocele which he had that day removed by castration from the person of a patient 74 years of age. It presented some points of interest, which were dwelt upon by the exhibitor.

Dr. Formad presented a specimen of supposed typhoid lesions in a child fifteen months old. There was no history, as it was a coroner's case.

—A wealthy Lothario, who was blessed with a beautiful wife, called on a physician of one of our summer watering-places, to consult him about a severe pain in his back.

"What have you done for it?"

"Applied a belladonna plaster," replied Crœsus.

"Well," said the doctor, "give up the belladonna and stick to the Donna Bella, and you will be cured."

EDITORIAL DEPARTMENT.

PERISCOPE.

The Operation of Laparotomy: Hair-Pin (Three and One-half Inches) Introduced Into Rectum, and Removed from the Sigmoid Flexure of Colon

Dr. Thomas Bryant thus writes in the *Medical Press*, March 18, 1885:

Cases of laparotomy for the removal of impacted foreign bodies in the intestinal tract are not so common as to make the particulars of any special case uninteresting. The one here recorded is very exceptional, and it may be said very successful, since it went on from the first steadily towards recovery, although a pleurisy and bronchitic trouble complicated its progress. In the treatment of the case the greatest simplicity was observed. Simple iodine-water was the antiseptic employed, and Lembert's suture used to stitch up the wound in the bowel. The sutures were introduced through the peritoneal covering of the bowel before the walls were incised. The wound in this way being closed at once without any manipulation after the removal of the hair-pin. The use of cold, as maintained by Leiter's metallic coil, had doubtless a good effect in preventing peritonitis.

Nelson B., æt. 9, was admitted into Job Ward, Guy's Hospital, on January 13, 1885, under Mr. Bryant's care.

Patient had measles when quite a baby. When three years old he had rheumatic fever badly. He has never been a strong boy since that time, having had a small appetite, and never eating any meat, except a piece of rabbit, chicken, or fish. About three years ago he had a second attack of fever, which was not so bad as the first. When four years old he had a fall and hurt his head. For this he was laid up four months, being delirious at times. Has not shown any signs of permanent injury since to his mental powers.

History of Present Injury.—He had been in his usual health, attending school until June last, six months before his admission, when after a bath he was put to bed. About two hours later his mother found him fretting and crying, but it was late that night before he told her that he had pushed a long hair-pin, bent end first, up his rectum. Patient also told her that he had tried to get it out again, but could not. It was not until the lapse of several days that he suffered much pain. His father did not for a long time believe that he had done anything of the kind; consequently, he did not seek advice for two and a-half or three months, when Mr. Bisshopp, of Tunbridge Wells, saw him. At this time he was suffering from severe abdominal pain, coming on in paroxysms; sometimes he was screaming all night. Mr. Bisshopp made an examination per rectum under chloroform, and on pushing his finger up as far as he could reach, he could just feel the pin, apparently impacted in the wall of the intestine, or close outside. He could not get hold of it to remove it, and thought that the patient, on trying to get it away, must have pushed it into the gut. At first he was able to attend school, though now and then he was in pain, and stayed at home; but since the beginning of last November—that is, for ten weeks—he has been confined to the house, the pains coming on very suddenly. Three times the pain has been so great as to cause him to faint away, with much sickness and intense pain in the lower part of the abdomen on the left side. He has also had sharp twinging pains in the arms and legs. His mother says there is a gathering in his stomach, which causes him great pain when passing a motion. After a motion, he is better for a few days. The last was eight days ago. At times, he has bladder symptoms, and he has to micturate suddenly. And oftentimes when in these pains he is very helpless. Sitting over warm water relieves him in these paroxysms. Latterly, he has slept in bed in a sitting position.

Condition on Admission.—Patient is a fairly nourished, not very strong looking, little boy. On examination, the abdomen presents a very considerable degree of fullness on the hypogastric and both inguinal regions. The upper part of the scrotum and pubic regions are also full, giving somewhat the appearance of a hernia. There is resonance over the lower part of the abdomen, with the exception of the pubic region, which presents dullness. Both the inguinal regions are very tender to the touch, especially the right. When the left groin is pressed or touched, he likewise winces, and complains of pricking pain in the right groin. With careful touch, a hard body, feeling as though it might be the bent end of a hair-pin, can be felt, one inch at the inner side, and slightly below the left ant. sup. iliac spine.

January 13. Placed on middle diet. Eggs, ij. Pil. Doveri, iv. gr. o. n. s. o. s. Hot belladonna fomentations to be continually applied to the lower part of the abdomen. Ol. Ricini, ʒij.

14th. Urine passed this morning, neutral or slightly alkaline, pale straw color. No albumen. Contains some phosphates. Sp. gr. 1028. No blood nor sugar.

15th. Seen for first time by Mr. Bryant, who, having felt what he believes to be the pin one inch within the left anterior superior spinous process of the ilium, proceeded to operate for its removal. Patient having been placed under chloroform by Mr. Parsons, Mr. Bryant made an oblique incision, about 1½ inches in length, extending about half an inch from the left ant. sup. iliac spine inwards and slightly downwards. There was but little fat beneath the skin. The external and internal oblique muscles were carefully divided upon a director, as also the transversalis muscles. Mr. Bryant next carefully divided the transversalis fascia and peritoneum upon the bent end of the hairpin, which had been felt throughout, and served as a guide. The bowel was now laid bare, and grasped between the fingers and thumb upon the bent end of the

pin. The right groin was gently pressed during this step of the operation to keep the pin forward. The pin was found to be lying obliquely in the direction of the skin incision, namely, with the bent end towards the ant. sup. iliac spine, and the forked end toward the pubes. Making the bowel tense over that end of the pin. Mr. Bryant then carefully divided it, previously passing two fine carbolized gut sutures through the margins of the incision. The pin was extracted from what was probably the sigmoid flexure of the colon, and proved to be a very large one, 3½ inches in length, and black pointed. The gut sutures in the bowel were now carefully tied, and the peritoneum and skin incision sewed up with three carbolized gut sutures. The wound was washed with iodine water. Two narrow strips of India rubber straping were placed between the stitches. A pad of iodoform gauze was then laid over the wound, and one of cotton wool superposed, and the whole kept firm with a spica. It should be stated that while the patient was under chloroform, and prior to operation, Mr. Bryant passed his finger up the rectum, but could not feel the pin, as it was out of reach. He did this thinking the pin felt rather deeply placed from the front. There was very slight bleeding during the operation, only two small vessels requiring to be twisted. On being replaced in bed the patient cried a good deal from pain, and was ordered tinct. opii, gr. iv., aq. chloroform ℥j., every four hours. Cold was applied to the wound by means of a Leiter's coil, and iced soda water and milk was ordered. So far as could be judged, he had borne the operation well. . Pulse E. 96.

16th. About 1 a. m. his pulse was about 120, and very hard. He was sick twice about 1 o'clock, but afterwards spent a very quiet night comfortably dozing, and suffering little or no pain. This morning his temperature was 103, and his pulse hard and bounding, 112 per minute. The bowels had not acted since the operation. Passed about three ounces of muddy urine, acid, sp. gr. 1020, full of lithates and urates, no albumen, no sugar, and almost total absence of mucus, no pus, no blood, salmon-colored. The lower part of the abdomen is tender, and the patient cries out at times with pain. Was seen by the house surgeon at about 12 noon, who found his pulse 124, and considered there was some peritonitis. Towards 5 p. m. patient seemed worse, his breathing being rapid, respiration 40, and his face flushed. Prior to this he had been ordered pil. opii, gr. ½, every four hours. On examination with the stethoscope symptoms of both bronchitis and pleurisy were revealed. His pulse at the time was 120. A mustard plaster was applied to his chest. There was a pleuritic rub on the right side especially, and rales on both sides of the chest.

17th. At 2:30 a. m. his pulse was 120, respiration 60, temperature 99.2°. Had five ounces of milk given during the night, and a Dover's powder, gr. v., at 2 a. m. and 6 a. m. At 10:30 a. m. his temperature was 99°, pulse 110, and respiration 44. His face was pinched and drawn, considerably flushed, but the breathing was rather better. Every now and then he coughs a little, which appears to hurt him very much. Two specimens of urine passed during the night were examined, both were very turbid, and salmon-colored, with profuse deposit of urates, contained no albumen, acid, no sugar, mucus, or pus, sp. gr. respectively 1042 and 1045. The high sp. gr. is probably due to the small quantity passed, four to five ounces each time, and larger percentage of solids to liquids. The pulv. doveri, gr. v., was ordered to be repeated every six hours. At 11:30 a. m. a steam kettle was placed beside the patient for inhalation. During the afternoon his condition remained unaltered, the cough was rather more troublesome, perhaps. He passed a pretty fair night, his temperature being at no time above 99°.

18th. There is some cyanosis in the patient's appearance this morning, his pulse and respiration are much the same as last evening, namely, 128 and 44 respectively. His temperature is rather higher, 101.5°. The urine passed this morning was more in quantity, a full pint, and clear, rather darker than the normal, sp. gr. 1037, no albumen, sugar, mucus, blood, nor pus. Acid re-action gave a white proportion of phosphates on boiling, which cleared up with nitric acid. Patient seems brighter this morning. The bowels have not yet acted. He seems fairly comfortable. Later in the day, his temperature rose, and at six p. m. reached 103.2°, at night he was slightly delirious. Vin ipecac, ℥. ix.; oxymel scilla, ℥. xx.; syr. tolut, ℥ss.; aq. ad. ℥j., every four hours; milk, ℥xij. At ten p. m., his temperature had fallen again to 100.2°. As he seemed very low, brandy, ℥iij., was ordered. ℥iij. every three hours.

19th. At one a. m., brandy, ℥iij., milk, ℥xij., ice. Repeat pil. doveri, gr. v., every six hours, repeat mixture every six hours, omit ice-bag to head, soda water. At six a. m. this morning his temperature had fallen to 98.2°, and he seemed much better in his breathing and general condition. The Dover's pill had been ordered in the night for the pain of the cough. The bowels have not yet acted; ice is given frequently to suck. Examined urine passed this morning, cloudy, salmon-colored, full of urates, slightly acid re-action, no albumen, sp. gr. 1037, no blood, sugar, and a very slight proportion of mucus. At 8:30 p. m., brandy omitted.

20th. The improvement in the patient's condition is maintained, patient breathes much better, and the temperature is lower; he takes interest in what is going on around him. He passed a fairly good night, sleeping from 12 to 3:30 a. m., and not being much troubled with his cough; he was not delirious in the night; steam-kettle left off to-day. Passed about half a pint of dark yellow clear urine of neutral or very slightly acid re-action, of sp. gr. 1033, contains no albumen, sugar, blood, or urates.

21st. Temperature this morning 98°, respiration 28, pulse 100. Looks very much better, passed a very good night. The same treatment was adhered to, ice to suck, milk, ℥vj., and soda water. Pill given at 12 and 6 a. m., and medicine at same time. The stitches were taken out of wound to-day, good union having taken place. The appearance was healthy, there was but little redness around thd edges of the wound and less tenderness round the part; the abdomen was not so distended as when the patient came in; milk, ℥vj. Dullness over left base, coarse crepitations all over,

slight tubular breathing at angle of scapula; cough troublesome and painful.

22d. Patient passed a good night, and there has been no further rise of temperature. His cough was rather troublesome this morning, pulse was 106 and stronger; he is looking very much better, the bowels have not yet been opened. Omit pil. Doveri at 12 a. m. and 6 p. m., Milk, Oj.

23d. The pleuritic rub has disappeared. He passed a fair night, but the cough was more troublesome, the Dover's pill was ordered to be repeated every twelve hours; milk, Oij., beef tea, Oj. In other respects patient is doing very nicely, his breathing is more easy, he takes his food well.

24th. Again passed a good night, has no pain from the wound except when pressed. His temperature for the last two days has not risen above 99°; repeated pil. Doveri, gr. v., om nocti. Dressed to-day. Washed wound with warm iodine water, and applied iodoform and lint. All going on very nicely. There is still tubular breathing at the right side.

25th. Continued improvement to record to-day. Ordered enema oliva, ℥iv.; beef tea, Oj.

26th. The bowels acted well during the night from the enema (the eleventh day after operation). Patient looks very well this morning; the Dover's pill was ordered to be left off, and the Leiter's coil to the abdomen omitted. The mixture to be again repeated, and two eggs, beaten up in milk, given. Examination of urine—normal color, alkaline re-action, sp. gr. 1030, no albumen.

27th. Passed a good night. Was sitting up in bed this morning, evidently fast improving. Temperature 98.6°. His cough is much less troublesome. Repeat mixture three times a day. Fish, bread, and butter.

30th. Wound dressed; it has nearly healed up. There is now no abdominal swelling nor hardness. Patient has nearly, if not quite, lost his cough, and is doing well in every respect.

February 2d. Patient is still making good progress. Has never passed any blood or pus with his motions. Got up for the first time in the evening.

6th. Has been getting up daily for a few hours; this morning the first thing, and is apparently none the worse.

8th. Discharged. The wound has quite healed up, and the boy seemed well in every respect.

Antipyrine in Sunstroke.

Dr. Benjamin F. Westbrook thus writes in the *N. Y. Med. Jour.*, July 25, 1885:

My object in publishing this note is to call attention to the use of antipyrine in two cases of sunstroke, so that others may, if they think proper, test it and contribute the results of their experience.

It occurred to me that the prompt introduction of an antipyretic dose of this substance into the subcutaneous tissues might be of great service in reducing the temperature, and so give time for attention to the treatment of the other pathological conditions. The ambulance surgeon, Dr. Folker, was therefore requested to provide himself with a fifty per cent. solution, and, in the event of his being called to a case of the apoplectic form of the disease, to administer a drachm of the solution hypodermically at once, and to repeat it in an hour, if the temperature was not markedly reduced. Other measures for the relief of the patient were, of course, not to be neglected.

"On Saturday, the 18th, when the thermometer registered 99° F. in the shade, he was called to attend a young Englishman, twenty-two years old, of very robust habit, who, after working out of doors all the forenoon, became comatose and convulsed after reaching his home at midday. The head was congested, eyes suffused, pulse rapid and strong, skin dry, and the coma profound. The bowels had moved spontaneously, and he had vomited freely. The rectal temperature was 109° F. The doctor administered a drachm of the fifty per cent. solution of antipyrine hypodermically, applied ice to the head, and removed him to the hospital.

"In the confusion attending his admission the extra time was not noted, but in about three-quarters of an hour after the first dose the rectal temperature was 107.5° F. Cold was applied to the body and head by means of towels wrung out of ice-water and frequently changed; and another drachm of the solution was introduced under the skin. In thirty minutes the rectal temperature was again taken and found to be 99°F. The cold applications were at once discontinued and dry heat was applied to the surface, while whisky was injected subcutaneously.

"When I arrived shortly afterward the surface of the body was cool, the pulse 120, the coma profound, and all the limbs were twitching convulsively. The head was still congested, the conjunctivæ injected, the pupils contracted but responding feebly to light, and the respiration was irregular and accompanied by a loud expiratory groan, such as is heard in severe cerebral disturbance. I gave two ounces of whisky and forty grains of chloral hydrate by enema, but they were not retained. About half an ounce of whisky was then given hypodermically. In half an hour the temperature began to rise slowly, so that the surface was warm. The twitching of the voluntary muscles became more marked, and he was seized with a most violent tetanic convulsion, which was controlled by chloroform. As the convulsions succeeded each other with increasing rapidity and intensity, I opened the median basilic vein and withdrew thirteen ounces of blood. The bleeding was terminated sooner than was desirable by the onset of a terrific convulsion, during which the arm was twisted violently and the opening in the vein occluded. After this there were no more severe convulsions; the patient became more quiet, and the rectum retained forty grains of chloral hydrate. This was followed by a period of rest, during which the axillary temperature was taken and found to be 103.7° F.

"One drachm of Lente's solution was thrown under the skin, and repeated about once in two hours till four doses were administered. At 8:15 p. m., as slight convulsions had occurred from time to time, six leeches were applied to the temporal regions, twenty grains of antipyrine given hypodermically, and forty grains of chloral hydrate by the rectum. From this time on he slept quietly, the temperature slowly declining until Sunday morning, when it was 99° F.

"At about ten o'clock on Saturday evening the patient first became sufficiently conscious to partially respond when spoken to, and from this he passed into a condition of hebetude, which, by Monday forenoon, had given place to complete consciousness. The temperature has been normal since Sunday afternoon, though the pulse is still somewhat rapid. He takes nourishment well. From Sunday morning to Monday morning he had forty grains of sodium bromide every two hours, and five grains of the sulphate of quinine every four hours. The doses were then reduced to twenty grains and two grains."

This case represented the severest type of sunstroke. I have never before seen so bad a one recover. The temperature was high, the coma very profound, and the convulsions the most terrible that I have ever witnessed, except in one case of tetanus, the subject of which died within twenty-four hours after the diagnosis was made. The rapid and permanent reduction of temperature, which must have been mainly due to the antipyrine—inasmuch as the cold applications were only continued for half an hour—undoubtedly coontributed toward the favorable result by giving time and removing at once the injurious effect of the hyperpyretic blood upon the higher nervous centres. The beneficial effect of the abstraction of blood was evident.

The second case was brought in an hour or two after the first, and while I was in the hospital:

"The patient, an Italian laborer, had been engaged in some laborious work upon the new building of the St. John's Orphan Asylum, which was destroyed by fire last winter. He became suddenly unconscious, had well-marked convulsions, and voided his excrement involuntarily. When Dr. Folker, our very competent ambulance surgeon, arrived, he was comatose, breathing irregularly, with rapid and tense pulse, suffused conjunctivæ, dry skin, and continual convulsive twitchings of all the voluntary muscles. The rectal temperature was 110° F. The doctor gave him a hypodermic injection of one drachm of the fifty per cent. solution of antipyrine, applied ice to the head, and brought him to the hospital. On his admission he was comatose. The surface, to my surprise, was cool. The pulse was 120, as nearly as it could be counted, with marked tension and a laboring stroke of the heart. The respiration was rendered irregular by the continued spasmodic movements of the voluntary muscles.

"The convulsive movements of the limbs were very peculiar, differing from any that I had seen before, in that they were rhythmic in character, and most readily likened to those of a man pulling upon a rope. The rectal temperature, thirty-five minutes after the administration of the hypodermic injection containing one half drachm of antipyrine, was 101° F.

"*No cold applications were used in this case, with the exception of ice to the head.* He was given, by enema, four ounces of whiskey and thirty grains of the hydrate of chloral, and retained it.

"After a time he became quiet, the convulsive movements almost entirely ceased, and consciousness became dimly perceptible. But, upon changing him to another bed, the peripheral irritation threw him into an active tetanic convulsion, which, however, soon subsided spontaneously. It was noted afterward that any pronounced peripheral irritation would produce convulsive movements. After an hour he received another half-drachm dose of chloral hydrate, with two ounces of whiskey, *per rectum*.

"He also received a drachm of Lente's solution of quinine about once in two hours. On Sunday morning he was quite conscious. The temperature was 99° F. He was ordered twenty grains of the bromide of sodium every two hours and three grains of quinine every four hours. On Monday his condition was still better, his mind, apparently, quite lucid, and his desire to move about and partake of food very decided. The bromide and quinine were continued."

The favorable termination in both of these cases is significant, as they were both accompanied by great hyperpyrexia and signs of a most profound vital disturbance. The first case was, probably, slightly injured by the use of cold applications too long continued, but this was quite excusable on the part of the house staff, as they were dealing with a new remedy, and had been advised not to neglect the old ones. The result in the second case would seem to strongly indicate that, where antipyrine is used, the external application of cold is not necessary. Another interesting observation was that, when the temperature declined, the cerebral symptoms still continued. This might indicate that even a short period of such intense heat and arterial excitement may so benumb the vaso-motor apparatus that several hours are required for recuperation.

If this is the correct inference, an agent like antipyrine, which is capable of reducing the temperature quickly, may be of the utmost importance.

But, of course, further observation is necessary before any positive conclusion can be drawn. From our experience so far, I should say that half a drachm of the drug would be sufficient to accomplish the purpose. A fifty per cent. solution is easily made, and, when injected beneath the skin, produces very little irritation.

Intra-Cranial Syphilis.

To the Glasgow Pathological Society (*Glasgow Med. Jour.*, July, 1885,) Professor M'Call Anderson showed a case of intra-cranial syphilis, and gave the following notes of the clinical history:

The patient, a clerk by occupation, and 37 years of age, was admitted into Ward II on the 10th of March, 1885. His family history is good, but he was always considered a delicate child, and after leaving school, while employed in a coal-pit, he contracted inflammation of the right lung. Nine years ago he became a clerk, but his employment did not involve very close confinement.

About six months before admission, on rising from the sofa, he felt a curious sensation in his head; his face was drawn to the left side, and his right arm was twisted up behind him. He was able, however, to walk to the door and call for help, but immediately thereafter he fell to the ground unconscious. His friends said the attack lasted about ten minutes, during which time he "frothed at the mouth;" the face was drawn at

the left side, and the right side of the body was convulsed. On regaining consciousness, he felt exhausted and inclined to sleep. Five weeks after this he had a second fit, which was not severe. On this occasion, he fell suddenly to the ground, was convulsed on the right side, but retained consciousness. After that he had attacks daily until three months ago, when under the influence of treatment, they ceased, and have not recurred. Before each attack, he had a feeling of giddiness for some time, and immediately preceding it a curious sensation in the palm of the right hand. Nearly from the first there has been constant trembling of the right hand, and for three or four months the right arm and leg have been gradually becoming weak. Almost from the first, too, he has been troubled with attacks of pain limited to the right side of the head, which soon became very intense, and which continued for hours, but for the last three weeks they have not been so severe.

For about three months there has been pain in the right hip-joint which, however, is not limited to the joint, but extends a little way up the side. For some weeks, too, he has been troubled at times with giddiness, and with dimness of vision, which appeared to him to be limited to the right eye. In consequence of this, on more than one occasion he came into collision with vehicles passing him in the street on his right side.

There is considerable improvement in his condition now (on admission), for not only has he had no convulsions of late, but the hemicrania is much less severe; the paresis of the arm and leg is less distinct, although he still occasionally strikes the floor with the sole in advancing the foot, and the dynamometer registers only 55 on the right side, as compared with 85 on the left. Indeed, the most marked feature in his case at present is hemiopia, which I now demonstrate to you. The following is Dr. Reid's report: "With the right eye he cannot see an object which is placed the least to the outside of a line drawn directly through the middle line of the eye. With the left eye the defect is discovered on bringing an object towards the inner side, but the defect is not so great as with the right. . . . The ophthalmoscope gives negative results."

With regard to the seat of the lesion, it was evident that it was at the base of the brain on the left side, because of (1) the paresis, (2) the convulsions, and (3) the tremors of the hand, all on the right side. The hemiopia was due to implication of the left optic nerve behind the commissure. The nature of the tumor was evidently syphilitic, because of the scar of a sore on the penis, followed in some months by sore throat, and by numerous sores on the dorsum of the tongue, and because of alopecia and nocturnal pain in the hip-joint.

Under treatment by the mercurous oleate of Shoemaker, all the above symptoms had almost entirely disappeared, and the hemiopia was nearly completely gone.

Dr. Thomas Reid thought that it was a clear case of affection of the optic nerve behind the chiasma. It seemed to him that the diagnosis and treatment had been much more efficacious than was usually experienced in such cases.

Dr. Tennent said that, with regard to the duration from the period of infection to the development of nervous symptoms, he had recently a case, which Dr. Thomas Reid also saw with him, in which the remarkable feature was that a period of twenty years had elapsed since the primary infection. At the time of the infection he had been treated for two years with a good result, and had experienced no evil consequences till the onset of the nervous symptoms. In this case the result of treatment had been most successful. He had seen nervous symptoms result from syphilis after 18 months.

Dr. W. J. Fleming had seen the case, and treated him for his sore tongue with Dr. Mungall. He regarded it as clearly a specific affection, and he rapidly got well under the original treatment.

Intermittent Albuminuria without Apparent Disturbance of Health.

Dr. Merklen, of Paris, reports this case in the *Med. Press*, July 1, 1885:

The patient, a youth sixteen years of age, had usually enjoyed good health, but, being the son of gouty parents, he himself presented the characters of the lymphatic temperament, extremities cold and blue, pale complexion, the limbs of exaggerated growth as compared with the trunk, and delicate skin, with a tendency to acne. Towards the end of last September he was seized on two successive occasions, after taking horse exercise, with sudden and fleeting loss of vision. This occurrence led to consultation of a medical man, by whom it was suggested that the urine should be examined, the result being that this excretion was found to contain a considerable quantity of albumen. This was the more surprising because the other organs were free from disease, and the general health was good, so that it was impossible to entertain the idea that nephritis existed. Provisionally, the patient was confined to his chamber, and put on a milk diet.

Careful and continuous examination of the urine for a week showed that a considerable quantity of albumen existed in it from midday to midnight, but not a trace during the intervening hours. This phenomenon, joined to the absence of any other suggestive symptom, excluded the supposition of a renal lesion, which was, moreover, rendered improbable by the non-existence of any casts, although the urine was several times examined for them. As a complement to this negative diagnosis the eyes were examined by the ophthalmoscope, the acuteness of vision was perfect, but the eye a little hypermetropic. Retinæ healthy, no traces of the lesions usual in albuminuria; the only anatomical peculiarity being a certain hardness (possibly congenital) of the optic nerve-fibres, and at one point a delicate injection of the same nerve. The retinal veins were relatively slightly turgescent, this being assigned to some atonic condition of the vaso-motors. The temporary impairment of vision was regarded as due to sudden suspension of accommodation in a hypermetropic eye, which was as suddenly rectified.

Two examinations of the urine passed at intervals of several days gave the following results: (1) Urea, 15 grammes, in 24 hours; uric acid, 59 grammes. Albumen in considerable amount, but

not found at night. The microscope reveals a very few leucocytes, and some epithelial cells. No sugar. (2) Urine passed between midday and 6 p. m. This contained eighteen centigrammes of coagulated albumen per litre.

The ophthalmoscopic examination having been productive of negative results only so far as regarded the retinal lesions usually found in albuminuric subjects, and the albuminuria itself intermittent and moderate in degree, the patient was permitted to return to school, and the rigidly enforced diet relaxed, but he was ordered to drink milk rather than wine, and to avoid severe exercise and chills. Continuous examinations of the urine gave the same results as previously detailed. On February 14, the patient was suddenly attacked with a violent fever, attended by pain in the side, and resulting in an acute chest affection having the characters, first of diaphragmatic pleurisy, next of pleuro-pneumonia. This feverish attack persisted twenty days, with sweating and sudamina; the condition of the patient was grave at times, the evening temperature varying from 39° to 40° C. The strange fact in connection with this period, however, is, that throughout it the urine never contained a trace of albumen, although examined at frequent intervals, and at all times in the 24 hours. Subsequently, the fever abated and convalescence was established, but the albuminuria did not return, although a meat diet was regularly indulged in at this time. Nor on getting up did it return, and a hope was entertained that the fever had exercised a curative influence over it. As soon, however, as the patient commenced to move about as usual this expectation was dispelled, and the urine being one day examined about this time, soon after breakfast (*dejeuner*), the characteristic albuminous precipitate was once more observed. Next morning it had disappeared, and thenceforward the same phenomena which were witnessed anterior to the fever were reproduced, but with the difference that as time proceeded the amount and frequency of the albuminous deposit grew less, and some prospect of amendment was apparent, with attending improvement in the patient's general health.

A Case of Convulsions During Pregnancy Treated by Injections of Pilocarpine; Recovery.

Dr. P. Horrocks thus writes in the *Lancet*, June 13:

E. N——, aged twenty-four, was admitted into Guy's Hospital on March 7th of this year under my care. She had been married fifteen months, and had had one miscarriage before the third month, in June, 1884. Before marriage she was a servant, but since she has done only her own housework. She had never previously had any fit, nor was there any tendency to fits in her relatives. Her father died of phthisis. Her own health has always been good. Her menstrual periods have been irregular, occurring at intervals varying from three weeks to two months. She is not quite sure when her last period occurred, but thinks it was in August, 1884, and believes herself to be seven months' pregnant. A week ago she began to have headache, which grew worse and occasionally she vomited. At 1 a. m. to-day (March 7th) she had a fit which lasted a few minutes, and after this at intervals of less than a quarter of an hour she continued to have fits throughout the day, each lasting from three to ten minutes. Ice-bags were applied to the head, and a purgative given, which acted. No urine passed during the day. Dr. Faraker, who was attending the case, sent her up to Guy's, where she was admitted at 9:20 p. m. The face was much swollen, and the body and lower extremities œdematous, and some blood was issuing from the mouth, the tongue being severely bitten on the left side. A catheter was passed, but only a drop of urine came away in it. Vaginal examination appeared to bring on the fits. A gag was placed in the mouth to protect the tongue. There was much lividity. Two fits took place in the first half-hour, the first being very severe, convulsing the whole body. Chloroform was administered, and it relieved the severity of the convulsions. A catheter was again passed, but no urine came away. At 10:5 p. m. a fourth fit came on during a vaginal examination. The fœtal heart was heard beating at the rate of 140 per minute. The patient has been quite unconscious since morning. At 11:30 p. m. a third of a grain of hydrochlorate of pilocarpine was injected subcutaneously, the patient being well wrapped up in hot blankets. In five minutes profuse sweating took place. At 12:10 a. m. (March 8th) another but much slighter fit came on. 2:15 a. m.: The sweating is nearly finished. She can be roused to some extent, but does not answer questions. A fourth of a grain of pilocarpine was injected, the patient resisting the puncture. Sweating began again in less than five minutes. Much of the lividity has disappeared. Temperature 101°; pulse 120, and less tense than it was. During the night the patient took some milk and brandy. She remained somewhat lethargic and did not speak in answer to questions, but put her tongue out when requested to do so. The left side of the tongue was bitten right through. At noon, and again at 5 p. m., a fourth of a grain of hydrochlorate of pilocarpine was injected hypodermically. Temperature normal; pulse 82. Five ounces of urine were drawn off; specific gravity 1020, acid, highly albuminous (nearly solid on boiling).—9th: No fits; temperature subnormal; took 23 oz. of milk; the tongue is in a very painful and swollen condition, the patient can scarcely speak for it; she is quite conscious. The mouth was washed out with a lotion of chlorinated soda.—10th: Bowels opened; urine passed normally; still albuminous.—11th: Urine acid; specific gravity 1015; albuminous.—12th: Passed 45 oz. of urine during the last twenty-four hours; less albumen.—13th: Colostrum in breasts. Fœtal heart sounds cannot be heard. Uterus seen to contract firmly at times; os patulous.—14th: Pain in abdomen; uterine contractions (?). Has complained of headache ever since she could speak.—15th: Albumen in urine is steadily diminishing in quantity. Still taking milk only.—16th: Labor pains set in, and a partly macerated dead fœtus was born at 4 p. m. The placenta was expressed after giving the patient chloroform, as she was too tender in the abdomen to allow it to be done without. Examination of the fœtus showed it to be between the sixth and seventh month. There was no ossific

centre in the astragalus. An interesting point about the fœtus was that the testes were completely descended into the scrotum.

It is not necessary to detail the further progress of the case. The patient made a rapid recovery, and left the hospital on March 28th with only a trace of albumen in the urine, a slight headache, and no œdema. She has been attending as an out-patient under my care since, and the last time she came up there was no albumen at all, and the headache had entirely disappeared. This is the only case that I have treated with pilocarpine, but the result was so immediate and so satisfactory that I thought it worth publishing. The patient had only one slight fit after the pilocarpine was commenced, and she seemed to improve rapidly. How it acted is less clear, but it seemed to me to relieve the system by causing the skin to take on the function of the kidneys vicariously.

Many believe that when convulsions come on during pregnancy the uterus should be emptied as speedily as possible. Others believe in venesection or anæsthetics, especially ether and chloroform. An interesting point in the present case is that the patient was relieved, and practically cured of the convulsions without emptying the uterus. Labor did set in, however, a week later, apparently spontaneously. It may be that the fœtus died in utero during the convulsions, and that labor set in consequently; but pilocarpine has been used for the induction of labor by Marsman, of St. Petersburg, and Clay, of Birmingham. Hence it may be that the injection of this drug set up the uterine contractions, which resulted in premature birth. Dr. Fordyce Barker, in 1879, condemned the use of pilocarpine in puerperal convulsions, asserting that it produced continuous and exhausting depression. In Clay's case there was very alarming depression; but this was a case not of convulsions, but contraction of the pelvis, in which the drug was given to induce labor. In my own case there was no depression to cause any anxiety. Hence I think the drug deserves further trial in these very distressing and often fatal cases.

Nitro-glycerine in Trigeminal Neuralgia.

Dr. S. P. Deahofe thus writes in the *Med. News*:

The successful treatment of the following case renders it of sufficient interest to merit reporting.

H. J. A., aged 55, a farmer, with whom I was personally acquainted, family history good, came to my office, September 27, 1884, with the following history:

He had suffered pain of a paroxysmal character in the right side of the tongue for the past four years. The paroxysms of pain had increased in frequency and severity, so that when I saw him he had as many as half a dozen or more attacks in an hour, the pain "darting in the tongue like a knife," to use the patient's expression, interfering with mastication and also with his speech, so that he would be compelled to stop talking until the pain ceased, which would be in a few seconds. There was also marked spasm of the facial muscles of the same side of the face, the mouth being drawn to the right side. The teeth remaining were perfectly sound. His family physician had treated him for "paralysis of the tongue, due to his teeth," to use the doctor's own language, with various remedies. He had also been treated from time to time by a number of other physicians, both regular and irregular, all making similar diagnoses excepting one, who called it neuralgia.

I diagnosticated neuralgia of the gustatory branch of the trigeminus, and informed the patient of the uncertainty of medicinal remedies in that affection, and the results of the operation of neurectomy. I concluded to try a few medicines first, and if they failed, then to perform neurectomy. Accordingly, I prescribed aconitia (Duquesnel's), in gradually increasing doses, for two weeks, but to no purpose, the paroxysms still increased in number and severity.

The patient, becoming very much discouraged, then demanded an operation, refusing to take any more medicine. I then requested a consultation with Dr. J. C. Reeve, of Dayton, Ohio. The day for consultation was set; but, being called to the country, the patient went to see Dr. Reeve in my absence. The doctor agreed with me in my diagnosis, and induced the patient to continue medicinal remedies yet awhile, giving him a one per cent. solution of nitro-glycerine, concluding, as he afterward informed me, that the lesion was central.

In a few days the patient reported to me a little better. I accordingly had the solution continued in doses of one minim three times a day, with the following results:

After taking the solution two weeks, he was completely relieved. He then neglected taking it for a few days, when the pain returned, but not so severe as before. I then ordered him to continue its use. After taking the solution sixteen days more, the patient was again free from pain, and it has not returned since, and he was able to eat and talk as well as ever. He also says his mind and memory are far better; that his taste, which was much blunted before taking the remedy, is now normal; and that his eyes are so much improved that he can now read print without his glasses, which was difficult to read with them before taking the solution—in fact, he says he feels like a new man.

A Remarkable Case.

Dr. James H. Aveling thus writes in the *Lancet*, July 4:

The patient whose case is here briefly narrated is a married lady aged 38, with a family. She is very intelligent, and has no history of hysteria or other nervous disorders. In October, 1884, one of her children struck her left eye with the back of his head. Six weeks after she felt something wrong with the eye. She also had noises in the ears, and tenderness of the nose, and pain of the back of the head when she stooped or had the bowels moved. Her speech also was affected. She hesitated and stammered when she spoke. These symptoms lasted and gradually got worse from December, 1884, to March, 1885, when she had three blisters on the back of her neck. The pain in the head now became constant, and caused sickness. During these three months the patient, besides her own medical man, had the

advantage of receiving advice from the following eminent members of our profession: Mr. McHardy, Mr. Couper, Mr. Hulke, Mr. Morell Mackenzie, Mr. Power, Mr. Cumberbatch, and Dr. Ferrier.

On March 22 the patient spoke to her medical attendant, Mr. Robert Mathews, of other symptoms which she had felt for a long time, but which she had not mentioned because she thought they could not have anything to do with her head troubles. She then described herself as having a constant feeling of weight in the pelvis, as if something were coming down, and that she could only pass a small quantity of water at a time with great effort. This statement induced Mr. Matthews to make an examination, when he found an "extreme anteversion of the uterus with a full bladder, the fundus of the uterus resting on, and making as it were a bed for itself in the bladder." He replaced the uterus, emptied the bladder, and, to his surprise, all the head symptoms disappeared. The relief, however, was only temporary, for the symptoms returned when the uterus fell forward into its abnormal position. At the suggestion of her husband, she tried the plan of lying with her hips raised on a high pillow, and when in this posture the head symptoms were relieved.

In April Mr. Mathews asked me to see the case, with the view of mechanically rectifying the position of the uterus. I found laceration of the perineum and os uteri, the latter being sufficiently patulous to admit the tip of the index finger. The uterus was large and congested, low down in the pelvis, and acutely anteverted, its fundus pressing on the neck of the bladder.

April 20. The patient having come to London, I replaced the uterus and retained it in position by one of Dr. Graily Hewitt's cradle pessaries. When I visited her the next day I found all the head symptoms gone. Eye, ear, nose, and head were perfectly well, and the speech free from hesitation or stammering. The only trouble left was vesical, and this was due to the pessary, which did not quite fit. After trying one of Thomas's anteversion pessaries without success, I introduced a smaller cradle pessary, and no further trouble with the bladder has been experienced.

The patient returned home, and on June 3d I heard from her. She wrote, "I am quite comfortable, and perfectly free from any kind of pain."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint before us, something over fifty cases of poisoning by chloroform are tabulated and examined by Dr. Llewellyn Elliot, of Washington, D. C. Rather more than one-fourth of these were fatal, either immediately from paralysis of the heart, or later from gastric inflammation. He adds one case from his own observation where recovery took place after the ingestion of two ounces.

——The last number o the *Sammlung Klinischer Vorträge* has an industrial as well as a scientific significance. It is by Dr. P. G. Unna, and is upon "Medicinal Soaps." The author has devoted a good deal of attention to this method of medication, and his opinions have corresponding value.

——"Diphtheria, as I See and Treat It," is the title of a reprint by Dr. T. J. Hutton, of Fergus Falls, Minn.

BOOK NOTICES.

Von Ziemssen's Hand-book of General Therapeutics. In seven volumes. Vols. I. and II., 8vo. William Wood & Co., New York, 1885.

The unwearied Von Ziemssen, who must have been born with a pen in his hand, which he has at no time since released from his grasp, has again stirred up his co-laborers, and gleaned the harvest-field of medical literature in the last decennium for the production of one of those voluminous works in which he, and apparently the profession of Germany and the United States, delight.

This "Hand-book," as he calls it (seven volumes of five or six hundred pages each)' is composed of a series of articles or monographs, each written by some prominent German physician on a particular topic of therapeutics. Thus, in the first volume, we have besides the introduction by Von Ziemssen himself, a treatise on the dietary of the sick and on the dietetic methods of treatment, by Prof. J. Bauer, and a monograph on the koumiss cure, by Dr. Stange. In the second volume are three essays, the first by Prof. Von Leibermeister on antipyretic methods of treatment, the second by Prof. Th. Jürgensen on antiphlogistic methods of treatment, and a third on epidermic, endermic, and hypodermic administration of medicines, by Prof. A. Eulenburg.

It is superfluous to say that these are solid and instructive articles. They have the German *Gründlichkeit*, and also the German *Weitläufigkeit*. Anglicé, prolixity and tedium. They are learned writers, these Germans, but dull! We wonder whether their big books are really read by American physicians, or only bought. But for reference they are excellent, and this treatise on therapeutics cannot fail to contain many valuable suggestions which will repay its perusal.

—Compressed tablets of vaccine lymph are manufactured and successfully used in Switzerland.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium.	**6.00**
Physician's Daily Pocket Record,	**1.50**
Reporter and Pocket Record,	**6.25**
Reporter, Comp. and Pocket Record,	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

CAN A CHILD HAVE LIVED IF THE LUNGS DO NOT CONTAIN AIR?

This interesting question, which, when affirmed, may greatly increase the number of convictions of infanticides, is debated at considerable length by Dr. Ullmann, in the *Vereinsbl. der Pfalz*, Aerzte 2, 1885:

In February, 1883, in Homburg, an illegitimate child was born in a bucket filled with refuse water, and remained in it for two hours without anybody coming to its aid.

The post-mortem examination proved that the fifty cm. long and 3,400 grm. weighing child had been born at full term and been capable of existence. The hair was dense, three cm. long, and nails and cartilages were fully developed.

Areolar tissue was injected with blood, the main veins of the neck were filled with blood, and in the left auricle about thirty grm. of dark blood were found.

Both lungs, completely free from air, sank in water. In the buccal cavity, the pharynx, the larynx, in the bronchi, up to their smallest ramifications, even to the very surface of the lungs, there were met with grayish, blackish ash-and-coal particles of the same kind as those present in the refuse water, into which the child had dropped immediately on being born; and in the stomach the same particles were found.

From these phenomena, Dr. Ullmann concluded that notwithstanding the absence of air in the lungs, the child lived after birth, as the particles mentioned could have penetrated as far as they did only by aid of a vigorous inspiration and swallowing. Otherwise, they might have been found in the mouth, the pharynx, and even the trachea, but they could never have extended into the finest branches of the bronchi.

In recent days, especially in Prussia, swinging is greatly practiced in the cases of stillborn children, the swinging motions, first recommended by Schulze, taking the place of artificial respiration. Dr. Runge draws our attention to the fact that this swinging, even if not successful as concerns the revival of the child, always has this result, that air enters the lungs. In all such cases the

lung-test, therefore, would not be an available proof before court. Suppose a mother is charged with having killed her new-born, and the lung test, proving the presence of air is looked upon as direct evidence of the child's having breathed, and been, therefore, born alive. If the nurse or the midwife had practiced swinging, the lung-test would not be admissable for the reasons above mentioned. Still physicians ought to be careful, and not propagate this knowledge, as it may be made use of for criminal purposes.

A SPECIFIC IN NEURALGIA OF THE FIFTH NERVE.

We possess at present a number of remedies which are of great service in neuralgias and other painful affections of the head. In common headache salicylate of sodium, if administered in doses of fifteen grains every three hours, has a splendid effect. In certain forms of sick headache, especially when the face has a flushed appearance, croton-chloral, given in doses of two grains and in pill form every two hours, rarely fails to bring relief. In hemicrania, if the face looks blanched, the inhalation of nitrite of amyl is the best remedy.

In neuralgia of the fifth nerve various drugs have been recommended from time to time. Are the attacks short but severe, and if they do not recur very frequently, hypodermic injections of morphia may be relied upon. In some cases large doses of quinine put an end to the seizure. Muriate of ammonia, fifteen grains every three hours, acts like magic in some individuals, while in others, especially when gastric irritability accompanies the attack, and still more, if nausea and vomiting usher it in, one or two grains of tartar emetic, if necessary repeated until emesis sets in, causes the neuralgia to disappear.

Recently a new remedy has been brought forward, which promises to become *the* specific in neuralgia of the trigeminus. Dr. M. Schneider (*Allg. Med. Centr. Zeit.*, 49, 1885,) had a lady patient, who at long intervals suffered from severe attacks of this painful malady. These attacks lasted from one month to half a year, and were accompanied by the most excruciating pains. Five years ago such an attack had been stopped by large doses of quinine. Another attack, which had continued with little interruption for six months, finally yielded to morphia and iron. A month ago the patient was again attacked by her old enemy. None of the remedies formerly applied seemed to do any good. S. then employed as an experiment salicylate of cocaine. Two-thirds of a grain were injected hypodermically into the right cheek. A minute or two later the pain ceased, and did not return. The injection itself was painless, and produced no irritation.

A week ago Engel had a similar case. The patient, a young man, presented himself at the clinic of Prof. Engel in Medico-Chirurgical College. He suffered excruciating pains, and near the left ala nasi was a very tender spot. Thirty minims of a two per cent. solution of muriate of cocaine were injected into the skin near the point doulourenx. Scarcely a minute later the pain had ceased. The remedy surely merits a more extensive trial.

IRREGULAR SEXUAL DEVELOPMENT.

Two recent studies in our German exchanges give much food for reflection to the physiologist and the social philosopher.

One of these is by Dr. Geigel, and has for title, "The Variability in the Development of the Sexual Organs in the Human Species." The other is an opinion by Dr. Scholtz, of Bremen, in the case of a middle-aged man, who had long been subject to abnormal sexual desires.

Dr. Geigel has once more subjected the growth of the fœtus in utero to a careful study, with the view of ascertaining what it is that decides on the sexuality of the child. His results are in certain respects negative. His conclusion is that there is no room for a simply mechanical explanation of the fact of sex. He says: "We must content ourselves with saying that in every embryo there is an inherent tendency, the plus or minus of which decides its sexual evolution."

But there is one new fact which he brings out strongly, and that is the slow and imperfect manner in which in some cases both the sexual organs

and their correlated sentiments are developed, not only in the fœtus, but in after life. "The whole term of life," he remarks, "is often insufficient to develop the sexual contrasts which theory demands." Some men remain largely women, some women largely men, their whole life through. There is an emotional and intellectual hermaphroditism where there is no physical one.

At this point we may turn to Dr. Scholtz. In his specialty of medical jurisprudence he explains the perversity of the sexual instincts in certain cases by this undeveloped sexuality. "My observations have convinced me," he writes, "that in such cases the crime of pederasty is not merely a disgusting habit, or the refinement of debauchees, but a congenital abnormality of the sexual instinct; an abnormality which very often is revealed in a general physical condition approaching that of the female type."

Such cases he would consider as of inborn mental alienation, and thinks their proper place is in the wards of a hospital, or under medical surveillance, rather than in the criminal dock.

Doubtless, their scientific aspect is such as he describes. But the social economist may well inquire whether a criminal punishment even in such cases is not better, as the fear of it will serve to stimulate the weak will-power of the feeble-minded, and will also be more of a terror to the deliberately perverse. For ourselves, we think it would be better, here as elsewhere, to punish the insane than to afford the sane an excuse to escape the proper chastisement for their crimes.

Notes and Comments

Alcoholic Paralysis.

The immediate and transient effects of an excessive quantity of alcohol upon the human nervous system, whether they are manifested in the form of drunkenness, or of delirium tremens, or of an acute attack of insanity, are well known. Scarcely less evident are the effects produced upon the nervous system by a less excessive, but a more prolonged abuse of alcoholic drinks. These effects may be manifested either in a general failure of physical and mental power, or in a form of disease closely resembling progressive paralytic dementia, or in various forms of chronic insanity, or in epilepsy, or in neuralgia, or in paralysis. In the acute form of alcoholic poisoning, no change in the structure of the nervous system has been found, except that the meninges, in common with the internal organs and the mucous membranes, are the seat of a very decided injection and of a slight exudation. In the chronic form of alcoholism, a number of pathological changes have been discovered in the nervous system, which, however, vary greatly in different cases.

Of late years the paralysis, which results from the abuse of alcohol, has been accurately described by numerous observers, and the attempt has been made to discover the lesion of the nervous system, which is associated with this form of paralysis. Two cases which are reported by Dr. Henry Hun, of Albany, in *The American Journal of the Medical Sciences* for April, 1885, are typical examples of this disease, and contribute to a better understanding of it.

Dr. Hun has collected the recorded cases of alcoholic paralysis, and from their study he holds that we are justified in regarding it as a special form of disease, with the following symptoms: After a number of cerebral and gastric disturbances due to the alcoholic poisoning, the symptoms of the disease proper commence with neuralgic pains and paræsthesiæ in the legs, which gradually extend to the upper extremity, and which are accompanied at first by hyperæsthesia, later by anæsthesia, and in severe cases by retardation of the conduction of pain. Along with these symptoms appears a muscular weakness which steadily increases to an extreme degree of paralysis, and is accompanied by rapid atrophy and by great sensitiveness of the muscles to pressure and to passive motion. Both the sensory and the motor disturbances are symmetrically distributed, and the paralysis attacks especially the extensor muscles. In addition to these motor and sensory symptoms there is also a decided degree of ataxia. The tendon reflexes are abolished, and vaso-motor symptoms, such as œdema, congestion, etc., are usually present. Symptoms of mental disturbance are always present in the form of loss of memory, and in transient delirium.

The lesion is in all probability a degeneration of the peripheral nerve fibres and of the nerve cells in the cerebral cortex, together with a chronic congestion or inflammation of the pia mater. This lesion explains well the symptoms, although it is certainly curious that alcohol should not attack the spinal cord, but only the highest and

lowest part of the nervous system, if one may so call the cortex of the brain and the terminal branches of the peripheral nerves.

A Case of Dislocation and Fracture of the Spine; Extension: Recovery.

Mr. Reginald Harrison thus writes in the *Lancet*, July 18, 1885:

C. R——, aged thirty, was admitted into the infirmary on December 14, 1884, having sustained an injury to the back, due to a fall down a railway cutting, a distance of seventy-five feet. On examination, there was a swelling over the third lumbar vertebra. The vertebral spines could be traced from above downwards as far as the third lumbar vertebra, the spine of which was very prominent; below this there was a depression, the fourth lumbar vertebra not being within reach, and below this the fifth lumbar vertebra could be distinctly felt. There was no crepitus. The lower limbs were completely paralyzed, and sensation was absent up to an ill-defined line at the upper part of the thighs. She complained of great pain in the back and down the legs. There were retention of urine and incontinence of fæces.

An anæsthetic having been administered, the shoulders were fixed and a broad strap was placed around the pelvis, from which extension was made by means of pulleys. During the operation, the patient lay on her back, and gentle pressure was made over the third lumbar vertebra. This was felt distinctly to go back, and at the same time the fourth vertebra slipped into its position. A saddle-shaped splint being fixed on the back, she was removed to bed.

On examination the next morning, the pain in the back and legs was absent; she could lift her right leg a few inches off the bed, and move her left leg slightly. Sensation had returned to a great extent, especially in the right leg. There was no retention of urine or incontinence of fæces.

From this time the patient got gradually better without any bad symptoms, the muscular power and sensation in the right leg always being in slight advance over those of the left. The temperature was never higher than 100° F. The prominence in the lumbar region returned to a slight extent. She was kept in bed, lying on her back with her legs extended, until March 10, 1885, when a plaster-of-Paris jacket was put on; and on March 12 she got up for the first time. She was very weak, but quickly improved, and on April 28, 1885, was discharged, being able to walk about and do light work with perfect ease.

Chicken-Pox.

During a period of six years Dr. Semtschenko, of Kasan (*Wratsch*, 5, '85, Russ.), had the opportunity to observe in the orphan asylum in his city four epidemics of chicken-pox. Altogether 276 children became attacked by the disease. Two children had the disease three times during that period (1880 in March and December, 1881 in November, and others in October 1882, March 1883, and November 1884), and six children had each the disease twice, with intervals of from three weeks to one and a half years.

It is of interest to note that the epidemics always commenced in October or November, and continued until the following spring. In more than one-half of the cases prodromi were observed (want of appetite, general hebetude, etc.), and in from one to four days the eruption appeared, and more than two-thirds of all cases beginning in the face or on the hairy covering of the scalp. The exanthem continued from thirteen hours to one week; in 75 it at once spread over the whole body, while in 127 patients it took three days until the eruption had broken out all over. Fever attacked 213 patients, and this varied from 100° to 104°. Two patients died in consequence of complications—in a one year-old child empyema, and in a child fourteen months old, purulent synovitis of the right leg (in both, therefore, probable tubercular infection?) being the cause of the fatal issue.

Dr. S. instituted several experiments concerning vaccination. Where non-vaccinated children were vaccinated at the beginning of an epidemic, the vaccination—performed with fresh cow-lymph—was partly successful and partly not, *i. e.*, as regards its "taking."

Were the children taken sick with chicken-pox about the day they had been vaccinated, then the latter progressed much slower than usually, its course being retarded. Was the vaccination performed directly into a chicken-pox pustule, the vaccine pustule developed splendidly, and the re-vaccinations, done from such pustules, proved eminently successful without their ever transmitting the chicken-pox to the children thus vaccinated.

Epithelioma Clitoridis.

Dr. L. Sorbets (*Gaz. des Hopteaux*, 140,) reports a case of this very rare affection which he had observed in a woman aged sixty-three years. She had for fifteen months a very painful ulcer in the vulva, which was covered with a crust and surrounded by a hard ring.

On examination, a tumor was found which involved the whole clitoris. It was movable, and of the size and form of a thumb. The unevenly bordered and ulcerated surface bled easily and emitted a peculiar smell. There was no swelling of the inguinal glands or flow from the uterus. The doctor at once recommended an operation. To this the patient would not consent until six months had passed. The operation was done in the following manner: While an assistant held the sound which was introduced into the bladder, the operator passed two very strong threads smeared with wax through the tumor. This, in the meantime, had grown to the size of a walnut, and on account of its weight covered the orifice of the urethra. He then drew the tumor forwards and cut it from the tissues in which it was imbedded. The inconsiderable primary hemorrhage was stopped by cold water and by bringing the legs together. The latter and somewhat greater hemorrhage was stopped by pressure. The wound healed without especial trouble. The microscopical examination of the specimen was inadvertently omitted.

The author mentioned three similar cases reported by Vidal, as of syphilitic origin, and on this account not operated upon. As there were in these cases no swelling of the inguinal glands, the author is inclined to think it a similar affection to his own. Nelaton had the opportunity only once to treat an epithelioma of the vulva, also Trélat. The latter found in the literature only three cases of this kind observed by Churchill, and two by Charles West.

Retention of Placenta.

The *London Med. Record* tells us that in the *Meditz. Obozr.*, 1885, Fasc. vii., p. 697, Dr. Bronislava Paszkewiscz, of Piatigorsk, Tersky Government, reports the case of a weak anæmic peasant woman, aged 35, to whom he was called three days after the patient's sixth labor (at full term) to remove the retained placenta, persistent efforts by a midwife having proved entirely ineffectual. The author found the patient lying in bed soaked through with blood and discharge, in a semi-conscious state, complaining of agonizing thirst and sleeplessness, suffering from nausea and mucobilious vomiting, severe rigors, and fever (40.1° C.). The pulse was weak and small, 120; the belly tense, extremely painful and tender; the fundus of the womb was felt at three fingers' breadths above the navel. There were present a considerable rupture of the perineum, several lacerations of the mucous membrane and submucous layer of the vagina, and one-sided deep laceration of the uterine cervix. The placenta was found firmly adherent along its whole circumference to the uterine wall. It was removed piecemeal in six pieces by the fingers alone, the removal proving extremely difficult and prolonged, in consequence both of firm adhesion and the state of the patient, who repeatedly fainted during the operation, and constantly required much attention. Extraction of every piece was accompanied by free discharge of thick pus, the placental parenchyma being in a state of purulent infiltration. The uterine (or external) surface of the borders of the placenta was densely covered with villous or bristle-shaped excrescences of connective tissue, which undoubtedly pointed to an inflammatory origin of the adhesion. The improvement of the patient's state was immediate and striking. It remained steady, even in spite of a recto-vaginal fistula being produced eight days later by a clumsy midwife, who had employed for administering enemata an old-fashioned syringe with a tin nozzle.

A Danger from Drain Ventilation.

Although sanitarians thoroughly realize the danger from this source, yet the average physician is very apt to overlook it. Hence we reproduce the remarks of Dr. John C. Thorowgood from the *Lancet*. He says:

"Not long ago, when attending a young lady with ulcerated throat, I heard of a family several members of which were for a long time ill with troublesome ulceration of the throat, the cause of which was for a time a mystery. It was at last found out that the ventilating pipes in connexion with the drains of an adjoining building were not carried up above the roof, the result of this arrangement being that sewer gas found its way into the dwelling of the patients by the upper windows. Now, when so much is being done in the way of drain ventilation, it becomes obviously a most important matter for the ventilating shafts to be carried well above all windows that may be in proximity. In the heavy air of a town it is especially important to let the gas escape at an altitude where there is some air current to blow it away."

A New Bunion Splint.

In the *Brit. Med. Jour.*, May, 1885, p. 1110, Mr. R. J. Spitta describes a new splint, which he has contrived in order to maintain the great toe in its normal position after continual distortion from

badly-fitting boots, and in cases of bunion, or enlargement of the joint. The splint can be worn during the day, provided the boot be of a good size and with square toes. The apparatus consists of a well-fitting band of steel, suitably covered, about half an inch wide, passing round the heel from the base of the toe on the inner side, to a corresponding joint on the outer border of the foot, being kept in position by a shaped lacing-piece across the arch, and passing beneath the sole. To the steel band is attached, at its inner extremity, a rack and pinion, by which the toe can be drawn away from the median line to any extent desired, the pressure of the screw on the foot being relieved by a moulded steel plate, accurately fitted to the side of the foot, and which is cup-shaped over the joint or bunion, and covered with soft leather. From the screw and rack, a firm piece of metal is continued on to the end of the foot, and is provided with a leather stall, which laces round the toe and grasps it tightly. Gradual extension is applied, so that in a week or two the toe becomes quite normal in position.

Cerebral Surgery.

In the *Lancet*, May, 1885, p. 881, Dr. W. Macewen records the notes of a man, aged 36, who in August, 1883, fell downstairs and was rendered unconscious for twelve hours. In November, 1883, the patient was admitted into the Glasgow Royal Infirmary, with impairment of power in the left arm, accompanied by muscular twitchings and pricking sensations in some parts. A lesion was diagnosed in the motor cortex of the upper half of the right ascending frontal convolution, probably due to irritation set up around an extravasation of blood, due to the previous injury. In December the author trephined, and found a membrane-like patch over the surface of the brain, involving the arachnoid and pia mater along with the external surface of the grey matter; there was also blood effused into the substance of the brain in the ascending frontal convolution. All this was removed, the bone was replaced after having been broken up into several small pieces, and the wound was dressed with eucalyptus gauze. The patient made a perfect recovery without a bad symptom, and two months afterwards was able to do his ordinary work.

Gangrene After Vaccination.

In vol. xlii. of *Guy's Hospital Reports*, Mr. Clement Lucas narrates a case where gangrene occurred in a feeble, emaciated child, five months of age, after vaccination and as the result of it. Two attempts to vaccinate the child had proved unsuccessful; but, after the third, gangrene of the neighborhood of the punctures supervened, and the child died without special symptoms of note. There was no question of vaccino-syphilis in the case, for four other children were vaccinated from the same vaccinifer without difficulty or bad symptom, and the question of inherited syphilis in the child is hardly to be accepted from the data given. The only conclusion arrived at with a fair amount of reason was, that here was a case in which vitality was low from malnutrition, and that the insertion of the vaccine operated as any irritant would have acted on such a subject. Such effects occur at times, and emphasize the caution to which all public vaccinators are alive, in selecting fit cases for the operation, or perhaps, more correctly, in rejecting unfit cases. The boon of vaccination is not diminished by learning the truth, such as is honestly given here.

The Diagnosis Between Indurated Chancre and Herpes.

It sometimes happens that herpes of the penis presents itself under the form of a single patch of superficial ulceration, accompanied by some induration of the underlying tissues; there may be also a swelling of the inguinal glands, so that the diagnosis between this so-called chancriform herpes and some forms of indurated chancre is very difficult in the early stages. M. Leloir, however, calls attention (*Journ. de Connaiss. Med.*, April 2, 1885,) to the fact that when a herpetic ulcer is pressed between the fingers, a drop of serous fluid is squeezed out. This manipulation can be repeated several times with the same effect; in the case of chancre, on the contrary, a little fluid is seen on the surface, but the quantity is not increased by pressure. When the base of the herpetic ulcer is indurated, the hardened tissues can be flattened between the fingers, while, in chancre, no amount of pressure can change the shape of the nodule. This difference is explained by the fact that in herpes there is a localized œdema of the tissues, while in chancre the chief lesion is a hard infiltration, sometimes accompanied by sclerosis of the connective tissue and of the vessels.

Rupture of the Urethra.

An interesting case of rupture of the urethra and fracture of the femur and pelvis is reported by Dr. Randolph Winslow in the *Maryland Med. Jour.* The patient, a young healthy man, whilst straddling the rail of a scow, was jammed between

the boat and wharf. When admitted, he was found to have sustained a simple fracture of the femur on its upper third, and as he passed no water since the accident, a catheter was introduced into the urethra, but failed to enter the bladder, and seemed to enter an empty space. Considerable bleeding from the urethra occurred. A rupture of the urethra was diagnosticated, and as night had come on, no further attempt was made to enter the bladder with the catheter, but the urine was withdrawn by means of the aspirator. The next morning a perineal section was made, and after some trouble the cut end of the urethra was found, and a tube passed into the bladder. The left ischium was felt to be broken when the finger was passed into the perineal opening. No extravasation of urine occurred, and the wound gradually healed, the patency of the canal being maintained by this systematic introduction of sounds.

Strychnia in Diphtheritic Paralysis.

In the *Deutsche Med. Wochensch.* of May 7, Dr. Reinhard, of Bautzen, relates a case for the purpose of recommending the use of strychnia in diphtheritic paralysis. A boy, aged 3½, after an attack of diphtheria, suffered from symptoms of paralysis in various muscles of the body, his gait being uncertain and staggering, at the same time that the soft palate was affected. Tonic treatment, including iron, was of no avail, and twelve days later the symptoms had advanced so far that death seemed imminent from paralysis of the respiratory muscles, and the child's body hung limp over the arm when he was held up. Internal remedies were useless, as the power of swallowing was lost; recourse was therefore at once had to the subcutaneous injection of sulphate of strychnia, 1 milligramme (0.015 grain) daily. The very next day the breathing was quieter and the muscles were less flaccid, and only fifteen doses were required to establish convalescence on a firm basis. No undesirable symptoms were set up by the strychnia. Dr. Reinhard mentions this case, not as anything new, but as bringing an old remedy to the remembrance of his fellow-practitioners.

The Use of Vaginal Injections after Normal Child-Birth.

Dr. Simon Baruch, who has studied this question very thoroughly, thus concludes an article in *Gaillard's Med. Jour.*:

If the obstetrician will never introduce an examining finger into the parturient canal without brushing the nails and washing the hand with an antiseptic solution—if he will be careful to make his examinations rarely—if he will *express* the placenta completely by Credé's method and *extract* the membranes without haste—if he will ensure complete expulsion of all coagula and tonic contraction of the uterus—if he will *see to it* that the vulva has been well cleansed of all clots and stains by an antiseptic solution (not with a sponge), and that it continues to be kept clean—if he will have clean napkins, sprinkled on the outside with some strong antiseptic solution, placed upon the external genitals, and if the nurse's hand be strictly kept out of the vagina, the demands of modern midwifery will be fulfilled, and "all will go merry as a marriage bell," so far as puerperal fever is concerned.

The Uses of Cocaine.

Decidedly there is a future for cocaine. It is destined to have a permanent place in medicine, surgery, and dentistry. The scope of its uses is not yet defined, but it is safe to say that its applications are widening as experiments with it are extended.

We have been especially impressed with this fact in looking over the literature of the subject recently issued by the house of Parke, Davis & Co., Detroit. They have published several most interesting pamphlets. One is entitled "Cocaine in Dental Surgery," another is a working bulletin on the drug containing a variety of original material, and a third a well composed collation of what has been reported about it in home and foreign medical literature. These pamphlets will be sent without charge by the house to any one mentioning the name of this journal, and they are worth reading by all.

The same firm have devised a very handy and ingenious "cocaine case," which they sell at a moderate price, and which impresses us as the best of the kind we have seen.

Traction on the Umbilical Cord.

Whether or not it is wise for the accoucheur to make traction on the cord to aid the delivery of the placenta is a question that has been repeatedly argued from both sides. As a late contribution to the discussion, we note in the *Brit. Med. Jour.* (July 25, 1885), that Dr. George Smith, after an extensive experience in midwifery, affirms that gentle traction on the cord is a safe and judicious expedient, and does not induce spasm, and should be practiced in every instance. At the same time,

the uterus should be grasped by the right hand, which few only can perfectly accomplish. The advantages of this plan are that the third stage, the most anxious time for patient and doctor, is much abridged, there is less likelihood of hemorrhage, and whether anything be wrong or not can be quickly ascertained. Spasmodic contraction is an exceedingly rare occurrence, and is almost invariably associated with something amiss with the placenta itself, or it is more or less adherent. He has not seen spasm produced by snapping of the funis, when the fœtus has been dropped on to the floor, nor by any other untoward circumstance, under which the child is occasionally born.

Observations on the Cutaneous and Deep Reflexes.

Dr. Philip C. Knapp, of Boston, records, in the April number of *The American Journal of the Medical Sciences*, a series of observations upon the cutaneous and deep reflexes of 239 persons, from which he draws the following conclusions:

1. Absence of the plantar or cremaster reflex is usually pathological, depending upon a direct lesion of the reflex arc, or some cerebral disturbance.

2. Absence of the other cutaneous reflexes is not necessarily pathological.

3. Absence of the patellar reflex may be due to cerebral disturbance, especially in alcoholic subjects.

4. Ankle and patellar clonus are pathological.

5. The deep reflexes of the upper extremity are of frequent occurrence, and have no special pathological significance.

Excision of the Larynx,

This comparatively rare operation was performed by Mr. Henry Morris, on the 11th of July, for what turned out to be epithelioma. The patient had been suffering from severe laryngeal symptoms for four years; tracheotomy became urgent four months ago, and, more recently, constant spasm and dyspnœa, due to the pressure of the growth on the upper part of the tracheotomy-tube had rendered his existence unbearable. The growth was confined within the air-passages; it filled the upper part of the larynx completely, and the cricoid cartilage partially. The larynx was removed by cutting through the thyro-hyoid membrane, and the tissue between the cricoid cartilage and the first ring of the trachea. The gullet and pharynx were not opened. The patient nearly a week after the operation had not had a bad symptom.

The Treatment of Gall-Stone by the Elastic Bandage.

Dr. Qvisling states (*Tidskrift for Prakt. Medicin*, quoted in *Nordiskt Medicinisk Arkiv.*, Band xvi., Häft 4,) that in seven cases of gall-stone (two men and five women) he has seen good results follow the use of Martin's elastic bandage. Its action depends on the immobilization of the abdominal organs, by which the calculus is prevented from irritating the mucous membrane, and from causing reflex contractions of the muscular coat of the gall-bladder. The bandage is applied rather firmly over the upper edge of the hepatic dulness, as far down as the crest of the ilium, a piece of flannel being placed under it. It may be removed at night, if desired by the patient. Its use should be persisted in until the patient appears to be definitely cured.

Disinfection of Vaccine Lancets.

Dr. Wm. Fearnley writes to the *Brit. Med. Jour.*, July 11, that for the past three years he has not had a single "bad" arm after vaccination, and he attributes it to sterilizing the lancet by heating it in the flame of a match to dull redness immediately before the operation. As soon as the lancet is hot he wipes it to get away the charred mass, if any; then when he can bear the blade with comfort against his cheek, he operates on the arm in the usual way. Before adopting this process an arm now and then would be angry and inflamed; now he never sees hardly a blush on any arm. The thing is simple, because every house contains the means (lucifer matches) of thorough disinfection.

CORRESPONDENCE.

The International Medical Congress.

EDS. MED. AND SURG. REPORTER:—

You will oblige me by publishing my views through your columns in regard to the action of the profession of this country towards the International Medical Congress of 1887.

Though, physiologically, the tongue is the chief organ of speech, yet by its anatomical surroundings, it should keep silence, for it is the only internal organ that is situated in a horizontal position where it may remain quiet and steady. To keep it in natural bounds, it is surrounded by two walls, one of ivory, and the other of softer substance; but owing to the surrounding, overflowing rivulet, it is sometimes hard to keep the organ in its scope. Therefore, I submit a few statements in the interest of the Congress, hoping they may be taken for what they may be worth.

If the medical journals of this country will not cease to discuss questions of character, eligibility,

privileges, parliamentary rules, etc., be they right or wrong, there will be "much ado about nothing." In other words, there will be nothing to romp about, and there will be few, if any, of the foreign attendance at the next International Congress of 1887.

Being a European myself, nobody will doubt that I know the habits and customs of European medical men. I feel certain that the past course of the medical profession of this country toward, the organization of the International Congress is ridiculed by those whose attendance is expecteds and I anticipate that it will be a bar to their presence, thus endangering the success of the Congress. There is another peculiarity which I fear will not be approved by the foreign element of the Congress, which is the contemplation of the incredible privilege of securing membership in the Congress by simply registering and obtaining a ticket of admission. It must be taken into consideration that the International Congress is composed of the most eminent benefactors of medical science of all civilized countries, a majority of them being appointed by their respective governments, as, for example, Russia, who sends delegates appointed by the Medical Department of the Interior and by the Medical Department of the Army. Those men are chosen from Hommes de Lettres, who are a credit to their country. I am sure those who intend coming here expect to meet our most learned men, not those who are merely appointed by some local society, among them, very likely, many who are even deficient in preliminary education, to say nothing of medicine. An action of this sort will undoubtedly bring our organization into disrepute, and make us the laughing stock of the whole medical world. If the foreign members are compelled to comply with the order of the Committee on Arrangements, they will be forced to comply with that which they do not believe in, by accepting members without name or fame. I would warn those who seek fame without deserving it, that, though true, the love of fame may incite one to great and noble actions, it cannot render him truly virtuous, for virtue knows of no other motive than that of doing good.

"Fame follows in the noble train, but never is its object."

Besides, it is well known that those who are fond of fame are not very choice in the means of acquiring it. When their real motives are once discovered, instead of obtaining applause they receive the contempt of mankind, and thus defeat their own purpose. Therefore, let us throw away the idle editorials, discussions, and actions of the different local organizations, and come to facts. Let us take the advice of the old book, "Select from you, wise men of understanding, well known to your tribes, and I will place them over your heads." (Deut. i. 13.) Let the instructors and writers of medicine of this country come to the front and let them exhibit their skill, that it may enable us to prove that we have men in our country second to none; and we can be assured that the reputation which they make will be equally shared by every progressive physician in the land. A German physician settled in a certain locality in this country, in a very short time was looked upon as a man of learning, though no one knew anything about him, and when questioned as to the knowledge of his ability, the reply of one was, Germany has scientific men in medicine. This man never struck a pen or uttered a syllable towards the reputation of medicine in Germany, nor was he a member of the International Congress, or any other Congress, still he enjoyed a portion of the fame of the German scientists. The American dentists who have established themselves in European cities, cannot attribute their success to their pre-eminence in dental science, but rather to the general reputation made by their progressive brethren in this country. If our medical men will be so fortunate as to make reputation at the next Congress at Washington, I feel assured we will all receive a benefit therefrom. Let the honor of the medical profession be as dear to us as our lives, let us not be easily provoked to anger and forced to repent some future day. Let us acknowledge the errors we have already made, and let us unite our efforts in active co-operation, not for fame, but for suffering humanity.

CARL H. VON KLEIN, M. D.

Dayton, Ohio, August 7, 1885.

FOREIGN.

The British Medical Association.

ABERDARE, August 6, 1885.

TO THE EDITOR MEDICAL AND SURGICAL REPORTER:

The annual meeting of the British Medical Association last week, at Cardiff, was a grand success. The scientific features of the meeting were of a high order. Address of Dr. Wm. Roberts, of Manchester, on Therapeutics; of Mr. Marshall, on Surgery; and of Mr. Dyke, on Forensic Medicine. The able and courteous management of affairs by the president, the genial cordiality of the profession in Cardiff, the hearty welcome given to the association by the civic authorities, and by all the leading inhabitants of Cardiff and its neighborhood, and the splendid weather which prevailed throughout the week, all contributed to render this meeting one than which it may be safely said none has been more pleasant and auspicious. Not only did the President and the local members do their utmost for the comfort and convenience of their guests, your humble servant was detailed as a guest of his lordship, the Bishop of Llndaff, at the Palace Llndaff; in all we were about twenty. The generous hospitality afforded from without the profession could not be surpassed. The Marquis of Bute showed his interest in the meeting by ordering that the Cardiff castle should be open to the members at any time, and by inviting a large number to a luncheon at the ruins of Camphilly castle. Lord Windsor gave a garden party in his beautiful gardens at Penarth, and the High Sheriff not only received several members as his guests at his house, but also gave a garden party. Pleasant drives to interesting places were given in the morning. On the last day we enjoyed a delightful excursion to Chipstow castle, Tintern Abbey, and Raglan castle.

In the sections valuable addresses were delivered by the several presidents, and several papers were read and discussed; but, as of old, too many papers and no time for discussion.

H. ISAAC JONES,

Of Scranton, Pa. M. D., L. R. C. P. E., &c.

News and Miscellany.

The Water-Supply of Ancient Roman Cities.

The *London Medical Times*, July 18, 1885, says: After the medals and certificates had been presented to the successful competitors at the exhibition held last year in Dublin, Professor W. H. Corfield read a paper on the above subject. He said that, as the supply of water to large populations was one of the most important subjects in connection with sanitary matters, and one upon which the health of the populations, to a very large extent, depended, he had thought that it would not be uninteresting to the members of this Institute were he to give them a short account of some of the more important works carried out for this purpose by the ancient Romans—the great sanitary engineers of antiquity—more especially as he had had exceptional opportunities of examining many of those great works. Many of them were well known, but others, in many respects by far the most important, had not received the consideration that they deserved. Of the aqueducts constructed for the supply of Rome itself we had an excellent detailed account in the work of Frontinus, the controller of the aqueduct under the Emperor Nerva. He wrote his admirable work on them about A. D. 97, and not only described the aqueducts as they were in his time, but also gave a very interesting history of them. Before 312 B. C. there was no systematic supply of water to the city; the water was got direct from the Tiber, from shallow wells, and from natural springs; but these sources being found no longer sufficient, the construction of the first or Appian aqueduct was undertaken. It was not a very long one, being little more than eleven miles. It was carried underground throughout its whole length, winding round the heads of the valleys in its course, and was thus invisible until it got inside the city itself—a very important matter, considering how liable Rome was, in these early times, to hostile attacks. It was soon found that a larger supply was required, and it was determined to bring water from a greater height and from a greater distance; the River Anio, above the falls at Tivoli, was selected for this purpose, and the aqueduct, the Anio Vetus, was no less than forty-two miles in length, and was also entirely underground, except at its entrance into Rome. Its exact course was not known, but during the lecturer's examination of the remains of the subsequent aqueducts at a place called the Porta Furba, near Rome, he had been fortunate enough to discover the exact position of the veritable Anio Vetus at that spot. These two aqueducts sufficed for the supply of Rome with water for 120 years; but in the 608th year A. U. C., the increase of the city necessitated a more ample supply, and it was determined to bring it from a still greater distance. Water was now brought from some pools in one of the valleys on the eastern side of the Anio, and the new aqueduct, called the Marcian, was 54 miles in length. Frontinus also gave the history of six other aqueducts in existence in his time, viz., the Tepulan, the Julian, the Virgo, the Alsietine or Augustan, the Claudian, and the Anio Novus; the last two being commenced by the Emperor Caligula, and finished by Claudius, because "seven aqueducts seemed scarcely sufficient for public purposes and private amusements." In order to allow of the deposit of suspended matters, piscinæ, or settling reservoirs, were constructed in a very ingenious manner. Each had four compartments, two upper and two lower; the water was conducted into one of the upper compartments, and from this passed probably by what we should call a standing waste or overflow pipe into the one below; from this it passed (probably through a grating) into the third compartment on the same level, and thence rose through a hole in the roof of this compartment into the fourth, which was above it, and in which the water of course attained the same level as in the first compartment, thence passing on along the aqueduct, having deposited a good deal of its suspended matter in the two lower compartments of the piscinæ. Arrangements were made by which these two lower compartments could be cleaned out from time to time. The specus or channel itself was of course constructed of masonry, generally of blocks of stone cemented together, and was frequently, though not always, lined with cement inside. It was roofed over, and ventilating shafts were constructed at intervals; in order to encourage the aëration of the water irregularities were occasionally introduced in the bed of the channel. The water supplied by the different aqueducts was of various qualities; that of the Marcian being very clear and good was used for domestic purposes. Frontinus gave the most accurate details as to the amount of water supplied by the various aqueducts, which it had been estimated was equivalent to about 332 million gallons a day, or 332 gallons per head per day, assuming the population of the city to be a million.

When we considered that we in London had only 30 gallons a head daily, and that many other towns had less, we got some idea of the profusion with which water was supplied to ancient Rome. But the remains of Roman aqueducts were not only to be found near Rome. Almost every Roman city, whether in Italy or in the south of France, or along the north coast of Africa, could show the remains of its aqueduct. There was, however, one city which, from the fact that a great part of it was situated upon a hill, was more difficult to supply with water than any of the rest, viz., Lugdunum (now Lyons), the capital of southern Gaul, built by Lucius Munatius Plancus, by order of the Senate, A. U. C. 711. A somewhat prolonged residence in this city had given the lecturer the opportunity of examining on the spot the remains of the aqueducts constructed there by the ancient Romans, and as they were but little known, although by far the most remarkable of the Roman waterworks, he would give a somewhat detailed account of them. Water was at first brought from the hills of Mont d'Or, near Lyons, where a plentiful supply was found at a sufficient height, viz., nearly 2,000 feet above the sea, and it was necessary to cross the broad and deep valley now called La Grange Blanche, and the Roman engineers making the aqueduct end in a reservoir on one side of the valley, carried the water down into the valley, probably by means of lead pipes, across the stream at the bottom of the valley by means of an aqueduct bridge 650 feet long, 75 feet high, and 28½ feet broad, and up

the other side into another reservoir, from which the aqueduct was continued, along the top of a long series of arches to the reservoir in the city, after a course of about ten miles.

In the time of Augustus it was found necessary to construct a second aqueduct, and the springs at the head of a small river, called now the Brevenne, were tapped, and conveyed by means of an underground aqueduct of about thirty miles in length. The lecturer exhibited a diagram showing a section of this aqueduct. The specus or channel was nearly two feet wide, and a little over five feet high, and was lined with a layer of one and one-fourth inches of cement. It was constructed of quadrangle blocks of stone cemented together, and had an arched stone roof. This aqueduct also crossed a small valley by means of inverted siphons. But neither of these aqueducts came from a source sufficiently high to supply the imperial palace on the top of Fourvières, and the Emperor Claudius determined to construct a third aqueduct. The sources of the stream now called the Gier, at the foot of Mont Pila, were chosen for this purpose, and from this point to the summit of Fourvières was constructed by far the most remarkable aqueduct of ancient times, an engineering work which reflected the greatest possible credit on the Roman engineers, and showed that they were not, as had been frequently supposed by those who had only examined aqueducts at Rome, by any means ignorant of the elementary principles of hydraulics. To tap the sources of a river fifty miles from the city, and to bring the water across ten or twelve valleys, one over 300 feet deep, and about two-thirds of a mile in width, was no easy task. At its source a dam appeared to have been constructed across the bed of the river, forming a lake from which the water entered the channel of the aqueduct, which passed along underground, except where it crossed certain small streams by means of bridges. In one or two places channels were cut for it through the solid rock, after which it reappeared on the surface at a point where now stood the village of Terre-Noire, and where it was necessary that it should cross a broad and deep valley. It ended in a stone reservoir, from which eight lead pipes descending into the valley were carried across the stream at the bottom on a bridge about twenty-five feet wide, and supported by twelve or thirteen arches, and then mounted the other side of the valley into another reservoir. Hence it again passed underground, except where it crossed valleys and streams, until it reached Soucieu, on the edge of the valley of the Garon, where there were still seen the remains of a splendid bridge, the thirteenth on its course, nearly 1,600 feet long, and attaining a height of fifty-six feet at its highest point above the ground.

The object of this bridge was to convey the channel of the aqueduct at a sufficient height into a reservoir on the edge of the valley. Four holes were still to be seen in that part of the front of the reservoir which was left, being the holes from which the lead pipes descended into the valley. It would appear from the remains of the reservoir that there must have been nine of these pipes in all. These holes were elliptical in shape, being 12 inches high by 9½ inches wide, and the interior of the reservoir was still seen to be covered with cement. The walls of the reservoir were about 2 feet 7 inches thick, and were strengthened by ties of iron; it has an arched stone roof, in which there was an opening for access. From this the nine lead pipes descended the side of the valley, supported on a construction of masonry, crossed the river by an aqueduct bridge and ascended into another reservoir on the other side, entering the reservoir at its upper part just below the spring of the arches of the roof. From this reservoir the aqueduct passed to the next on the edge of the large and deep valley of Bonnan, being underground twice and having three bridges on its course. The bridge across this valley had thirty arches, and was about 880 feet long by 24 feet wide. After crossing the bridge, the pipes were carried up the other side of the valley into a reservoir, of which little remained, and then the aqueduct was continued to the next valley, passing over three bridges in its course. This valley, that of St. Irenée, was much smaller than either of the others, but nevertheless it was deep enough to necessitate the construction of inverted siphons, of which there were eight. The aqueduct was then carried on a long bridge (the twentieth on its course), which crossed the plateau on the top of Fourvières, and opened into a large reservoir, the remains of which were still to be seen. From this reservoir, 77 feet long and 51 feet wide, pipes of lead conveyed the water to the imperial palace and to the other buildings near the top of the hill. Some of these lead pipes were found in a vineyard near the top of Fourvières at the beginning of the eighteenth century. They were made of thick sheet lead, rolled round so as to form a tube, with the edges of the sheet turned upwards, and applied to one another in such a way as to leave a small space, which was probably filled with some kind of cement. These pipes, of which it is said that 20 or 30, each from 15 to 20 feet long, were found, were marked with the initial letters TI. CL. CAES. (Tiberus Claudius Cæsar), and afforded positive evidence that the work was carried out under the Emperor Claudius. It would be seen at once that the great difference between this aqueduct and those near Rome arose from the fact that instead of being carried across a nearly flat country, it was carried across one intersected with deep ravines, and that it was therefore necessary to have recourse to the system of inverted siphons. The Romans had been blamed for not using inverted siphons in the aqueducts at Rome, and it had been said that this was a sufficient proof that they did not understand the simplest principles of hydraulics, but the remains of the aqueducts at Lyons negatived this assumption altogether. The Romans were not so foolish as to construct undergound siphons many miles long for the supply of Rome, but where it was necessary to construct them for the purpose of crossing deep valleys they did so. It is thus seen that the ancient Romans spared no pains to obtain a supply of pure water for their cities, and Dr. Corfield thought it was high time that we followed their example, and went to the trouble and expense of obtaining drinking water from unimpeachable sources, instead of, as was too often the case, taking water which we knew perfectly well had been polluted, and then attempting to purify it for domestic purposes.

On the Renewing of Prescriptions by Druggists.

The Paris correspondent of the *Med. Times* tells us that after a long discussion on this subject, in which was shown the danger to the public of allowing chemists and druggists to fill any doctor's prescription as often as it is presented, the Société de Médecine has given the following as its opinion:

1. That when a doctor prescribes any substance that is susceptible of causing an accident, he must write in full the dose, and the way it should be employed, and also indicate how often the druggist should renew it.

2. That the druggist should be compelled to write on the prescription the number and date every time he fills it.

3. That all solutions intended for hypodermic injection must never be renewed unless the physician gives a new prescription.

It was further thought by several members that it would be wise for druggists not to renew any dangerous prescription from any one they did not know, and to insist that doctors who want the prescription to be renewed should write on it, "To be renewed according to the demand of the patient."

Microscopic Photography.

A foreign exchange informs us that M. Viallanes, of Paris, has invented an instrument for microscopic photography; it has been constructed by M. Dumaige, and consists of two independent parts, the photographic microscope and the dark chamber. The tube is much larger than that of an ordinary microscope, which allows the image reproduced on the unpolished glass to extend over a larger area than the human vision can realize when looking through an ordinary microscope. This is an indispensable condition when not only the details of a preparation must be photographed, but the *ensemble*. The long tube is closed at the top by a piece of metal, on which an ordinary eye-piece can be placed. Thus this instrument can be used as an ordinary microscope. It is easily placed in a horizontal position. The dark chamber, similar to that used by photographers, moves along horizontally on a slide; underneath the slab that supports the preparation, an Abbé's condenser is placed, the glass of which is replaced by an electric incandescent lamp silvered on both sides. By means of a very simple arrangement, the lamp can be used as required.

A Curious Epitaph.

The *Boston M & S. Jour.* says that the following was found on a gravestone in a country churchyard in England, on Mrs. Arabella Greenwood, who died in childbed; written by Rev. Mr. Greenwood, D. D.:

O Deathe! O Deathe! thou hast cutte down
The fairest GREENWOOD in all this towne;
Her virtues and good qualities were suche
That shee might have married a lorde or a judge;
But such was her condescensione, and such her humilitie
She chose to take me, a Doctor of Divinitie,
For which heroicke acte, she stands confeste
Above all others the Phœnix of her sexe,
And like that birde one younge she did begette,
That she might not leave her sexe disconsolate.
Mie griefe for her is so verie sore
I can onlie write two lines more:
For this, and everie good woman her sake,
Never let a blisterre be putte on a lyinge-in-woman's backe.

Cholera in Europe.

The cholera epidemic in Spain seems to be on the increase, the daily deaths from the disease running from 1400 to 1900. Already the disease has claimed more than 70,000 victims in Spain, and shows no signs of abatement. In Marseilles, the disease has assumed a peculiar aspect. Without either vomiting or diarrhœa, the patient becomes cold and chilly, sinks into a collapse, uncontrollable by remedies, and dies in a couple of hours. The disease seems to have been particularly malignant in Spain; for out of some 160,000 cases, over 70,000 have died. This country has been particularly neglectful of preventive medicine: which only tends to add additional testimony to the fact that cleanliness and hygiene are foes to cholera.

Fear of Cholera in the Canary Islands.

Advices from Madrid, under date of August 12, say that the excitement among the people of the Canary Islands, caused by the fear of cholera, amounts to a panic. They now refuse to permit any persons from Spain to land. They made an exception in favor of the new Governor and allowed him to come ashore, but received him with riotous demonstrations, and threw stones at him. The local authorities have resigned, and many of the people have fled to the interior in fear of the approach of the scourge. At present soldiers occupy the streets and all the public buildings.

Yellow Fever.

A mild case of yellow fever in the person of a sailor from a ship from Southern waters has been recently treated in the Pennsylvania Hospital. There was some question as to the correctness of the diagnosis, the suspicion being entertained by some that the man was suffering from the effects of a prolonged debauch. No further cases have been reported.

Small Pox in Montreal.

Owing to the violent opposition to vaccination so prevalent among the French Canadians, smallpox every now and then breaks out in a violent form in Canada. At the present time, the disease in an alarming form is prevalent in Montreal. Owing to our intimate relations with Canada, we are in no little danger, and it behooves our Sanitary authorities to be wide-awake and vigilant.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the two weeks ended August 15, 1885.

Bailhache, P. H., surgeon. To proceed to Delaware Breakwater Quarantine as inspector, August 15, 1885.

Stoner, George W., surgeon. Granted leave of absence for thirty days, August 10, 1885.

The Mississippi Valley Medical Society,

Formerly the Tri-State Medical Society, meets at Evansville, Ind., September 8th, 9th, and 10th next. The railroads return members at one-third fare. Hotel rates: $1.50 to $2.00 per day. For further information, address Dr. A. M. Owen, Evansville, Ind.

Items.

—Dr. Fehling, of Stuttgart, the inventor of the well known test for sugar in urine, died on July 1, in his 73d year.

—In habitual constipation this pill will be found of value (Prof. Bartholow):

℞. Resinæ podophylli, gr. vj.
Ext. belladonnæ,
Ext. physostigmatis, āā gr. iij.
M. Sig.—One pill each night.

—The following test for oleomargarine is given by the *Therapeutic Gazette* as at once reliable and simple. A few drops of sulphuric acid when placed on genuine butter produce first a yellowish-white and after ten minutes a brick color, while oleomargarine treated in the same manner assumes first an amber and later a crimson color.

—Professor Tyndall has directed that the receipts from his lectures in the United States in 1872, amounting to some $30,000, shall be equally divided between the Universities of Columbia, Harvard, and Pennsylvania, with the view of founding science fellowships for men who wish to devote their lives to original research.

—The following combination, recommended by Dr. Fothergill, will be found a useful diuretic:

℞. Pot. citrat., ℥ iiss.
Spt. juniper co., ℥ j.
Tr. digitalis. ℥ iiss.
Inf. buchu ad., ℥ viij.
M. Sig.—One to two teaspoonfuls three or four times a day.

—In cities, a few handfuls of salt thrown into the water-closets, and an occasional handful thrown into the wash-basins, would go far, we believe, toward counteracting the noxious effects of the omnipresent sewer-gas, against which sanitary efforts have so long been directed. In the country, a quart or more of salt used daily in the privy vaults would serve an equally useful purpose.

—Mr. Clement Lucas removed (in Guy's Hospital, on the 14th of July,) a distended floating kidney, filled with large calculi, which could be felt through the abdominal parietes. The operation was performed without difficulty through the loin, leaving the peritoneum uninjured. The patient is progressing uninterruptedly towards recovery, her temperature continuing normal as before the operation.

—The Trustees of Columbia College, New York, have decided to add a course of instruction in sanitary engineering at the School of Mines, and it will be given to Dr. J. S. Billings, U. S. A., who will still continue to lecture on hygiene also. Special microscopical instruction will be under the charge of an assistant, and students who take the course for four years, and pass satisfactory examinations, will, on the recommendation of the Faculty, receive the degree of Sanitary Engineer.

—A correspondent of the *North Carolina Medical Journal*, reports an interesting case in which the secretion of milk was greatly stimulated by eating oranges. To test the effect, the fruit was omitted for a few days, when the secretion ceased. It was soon brought on, however, by a return to this fruit diet. If at any time the flow be not free, one or two oranges will increase it very abundantly in an hour or two. Previous to using the oranges, the patient gave no milk and the child was fed artificially.

An English medical paper says that "the care of babies has become quite a fashionable amusement among mothers," and attributes this growth of maternal solicitude to the innumerable "guides to nursing" published in England of late.—*Ex.* In connection with this statement, the following item from the *Providence Journal* may be of interest: Among the returns of death last month in this city was one of a young child, the cause of which was given by the physician thus: Cause of death—"'How to Feed the Baby' and its Boston author."

—In the *Bull. Soc. Chim.*, A. Gautier, writing on the action of bacterial ferments on albuminoids, by which certain poisonous alkaloids are produced, says that these seem to be identical with those commonly known as ptomaines; and proposes that, as they are constant and necessary principles in the normal excretions of living organisms, and have been detected in the saliva, urine, muscular juices, sweat, and also in numerous glands, they should be called "leucomaines" (*λεύκωμα*, the white of egg). They are mostly poisonous, crystalline, and give crystalline platino-chlorides.

—The French administration has just published (*Revue de Thérapeutique*, June 15,) an account of the expense that have been incurred for the arrest of the progress of cholera during its short visit of last year. Together, these amount to $210,000, distributed in sums varying from $56,000 in Algeria to $20 at Arriège. There are also charges of $18,000 put down for medical inspection at railway stations and at the frontier; $1,400 for mission expenses; $2,000 for quarantine on the coasts; $6,000 for deterioration of material lent by the war office; $2,000 for medals; and $20,000 for miscellaneous expenses.

—The *Centralbl. für Klin. Med.*, for May 23d, contains an original article by Dr. Rütimeyer, on the presence of tubercle bacilli in the blood and in the spleen in acute miliary tuberculosis. In several cases of the disease, he has examined specimens of blood obtained during life by puncture of the spleen with a syringe, and has been able to demonstrate bacilli in all of them. He has found this method to be much more certain than that of obtaining the blood by means of a puncture in the finger, and there is no great risk of any danger to the patient from escape of blood into the peritoneum.

—An Italian observer whose observations are recorded in the Naples *Giorn. Internazionale delle Scienze Mediche*, disbelieves the ordinary theory that acetone in the blood is the cause of diabetic coma. He says that acetone is not particularly poisonous, less so indeed than ethylic alcohol. He finds that aceto-acetic ether does not produce diabetic coma, but that it produces albuminuria and hæmoglobinuria, and is itself voided in the urine unchanged. Crotonic aldehyde is very poisonous, causing in a rabbit a train of symptoms comparable to those described by Kussmaul as characteristic of the coma of diabetes.

THE SEASHORE AS A HEALTH-RESORT.

BY HUGO ENGEL, A. M., M. D.,

Professor of Nervous Diseases and Clinical Medicine at the Medico-Chirurgical College of Philadelphia.

Be it typhoid fever, pneumonia, or any other acute or subacute disease, or any chronic complaint, which, not being based upon some structural lesion, has been cured by the skillful physician, we often notice, after the malady has happily ceased and convalescence begun in earnest, that a general debility remains, which is the worse and postpones the longer the greatly desired return to the active life of health, as the appetite does not seem to improve.

To the same class of cases also belong all those in whom a general lassitude and a disinclination to work have slowly developed themselves in consequence of mental overstrain or worry. And nowhere are such cases—of slow convalescence as well as those last mentioned—more frequently met with than in our large overcrowded cities.

For all these the best that can be recommended, is a change of air and scene. And here again, there is no place that can show better, more rapid and more lasting results than the seashore. A patient, who after having passed through an attack of some serious illness, might lie listlessly for weeks, ere gradually his strength returns, if he remain in the city, within a few days finds his appetite improved, feels once more the former elasticity in his limbs, when under the influence of the tonic sea-air.

For a better illustration let me cite two cases, both good examples of what I desire to state. In a large Import-House of this city a number of petty thefts had occurred of late. Wishing to catch the thief, the manager of the concern, W. K., æt. 34, concealed himself one night in the cellar of the warehouse. An hour later a severe rainstorm broke out, the water accumulated in the cellar, and the manager, who had been clad but slightly, as it had been very hot the whole day and evening, had to sit for some hours with his feet immersed in water and feeling chilly from the cool, damp night air. Toward morning he walked home, to obtain a few hours' sleep. In rising late he felt stiff all over, and suffered from pains in the neighborhood of the right groin. The next day he had high fever, several chains of the superficial abdominal glands enlarged, and later, two of them suppurated. After a week's illness, he lapsed into a typhoid condition, and for five weeks he was seriously ill. When finally convalescence began, the patient, formerly a strong and healthy man, could scarcely move; though he greatly desired to resume his duties, he had not strength enough left to raise himself up in bed. For a whole week this state of debility continued without any abatement. Nothing seemed to give him strength; nothing to bring back his appetite, though he had all possible attention, a tonic and slightly stimulating treatment, and the most careful nursing. At the commencement of his convalescence, I had advised him to go to the seashore; but he did not like to lose any more time, and consoled himself with the hope of a speedy recovery at home. But when two weeks had passed by without any great change in his weakness, he assented to the proposal. Although

otherwise healthy and free from disease, he had to be assisted into the carriage which was to carry him to the depot, and in the cars we had to support him with pillows. Arrived at the seashore he at once sought his bed. He had evidently lost all hope of a speedy recovery. That occurred near 12 o'clock, at noon. Soon after he fell asleep and had the first healthy slumber since his illness. He did not awake until evening, drew in deeply the cool sea-breeze, drank a cup of bouillon with more appetite than he had shown for weeks, and then fell once more into a sound sleep, which continued without interruption till the next morning, when he admitted his feeling better. He rose, dressed himself, and walked without assistance to the dining-room of the hotel, where he ate with more relish than we had anticipated. To make the story short, I will say that he made the most rapid progress; a few days produced a great change in him. After a week's sojourn at the seashore, he might have resumed his duties, but he followed my advice and stayed there nearly two weeks longer, when he presented once more the picture of health and vigor. During these three weeks he gained 29 pounds, weighing, when he left, 6 pounds more than to his knowledge he had ever been weighing.

Ch. L——, æt. 23, had been suffering for seven weeks from typhoid fever. After his recovery—though free from fever and from all other symptoms of his former disease—he remained for almost a whole month in an apathetic condition. He had no appetite, never asked for food, and looked with disgust at everything offered him. He took no interest in anything, and it was only with difficulty that he could be induced to sit in a chair, always preferring to remain in bed. Whenever he had been reclining in an arm-chair for the few minutes during which the bed was being made, he hastened back to the latter. Neither his young wife nor his only child, a handsome little boy of two years, could rouse him from his apathy. In this condition I saw the patient for the first time, and I at once advised his removal to the seashore. The same had been previously recommended to him, but probably not with sufficient authority and determination; I exaggerated his condition, and threatened him with a relapse if he did not obey; but on the other hand promised him a speedy recovery if he acted upon my suggestion. He assented, and left the next day. Three days later his wife wrote to me: "Charles walked with us on the beach yesterday and to-day. Though still easily fatigued, his ambition has returned, and with it his desire to live. This noon he scarcely could wait for his dinner; we had to give him some raw oysters to satisfy the cravings of his appetite. Isn't that a change? . . . The sailing seems especially to do him good. O, how he, as well as we all, now regret his not going sooner!"

A week later I saw him, and scarcely recognized in the sunburnt and hearty-looking young man the debilitated individual of a week before. As the people were well to do, I induced him to stay a month at the shore, and when he finally came home, he was stronger and healthier than he had ever been.

I could multiply these cases many times. But not all sick persons obtain the same success. While the seashore is undoubtedly the best possible resort for patients of the kind mentioned, a sojourn there does harm in other cases. I have never known a case of articular rheumatism to do well there, neither will a person with a rheumatic diathesis be benefited by the sea air. Then individuals suffering from organic disease of the heart or of the large blood-vessels, or all such with a tendency to the formation of emboli or thrombi, or of minute aneurisms in the brain, become worse at the shore, either while there or soon after their return. Physicians often send patients to the coast who are still laboring under the more direct sequelæ of cerebral hemorrhage. Whenever there is reason to dread another attack, my advice is not to permit such individuals to visit the shore, for they invariably get worse.

No patient affected with morbus Brightii, or with cirrhosis of the liver, should sojourn near the ocean, for all these will soon find their symptoms to become aggravated. Those suffering from chronic malaria often improve when at the seashore during June, July, and August; but during the remainder of the year, as also during the months mentioned, if it rains a great deal, they should shun that climate. But the most cruel of all is the sending of tubercular patients to the seashore. During the first stage, it is true, they often seem to improve there, but as a rule their disease will make the more rapid progress after their return. And when softening has set in, death is only hastened if such patients remain at the shore.

Which classes of patients, then, the reader may ask, are benefited by a sojourn near the coast? As mentioned, all those who have passed through an acute disease, and while free from organic lesions, have entered upon their convalescence. All those suffering from a chronic malady, not based upon an incurable structural change of the organs of respiration or circulation, and not accompanied by an incurable cachectic state of the

blood. Then all those affected with atonic dyspepsia, with gastric catarrh, anæmia (especially chlorosis), scrofula, the splenic variety of leucocythæmia, or with the consequences of some accident or surgical operation. Further, the majority of the great class of nervous diseases (especially functional)—with the exception of those above enumerated, and of locomotor ataxia and all brain and spinal maladies in which periodical congestions to the nervous centres occur, or in which a rheumatic diathesis is the pathogenic element—and all children, either convalescent from acute diseases, suffering from cholera infantum, or laboring under some chronic malady, a cure of which is possible, and if not belonging to the category excepted. All these will obtain their health quicker if they stay for a time at the seashore.

It would be impracticable to mention all cases that will or will not be benefited by a sojourn near the ocean. As a rule, if it is the intention to tone up the system, to enrich the blood, to strengthen the nerves, and if professional knowledge and experience tells us that there is hope, if these conditions can be complied with, these intentions be fulfilled—all such rapidly improve at the seashore; while if an organic lesion or a cachexia indicates to us the certainty of a fatal issue, this is only accelerated by a residence at the coast. Then there are certain special diseases, as mentioned above, where the sea air will either aggravate or improve the symptoms. Thus, I have never known a case of acute or chronic disease of the liver to do well at the shore; on the contrary, such patients, if permanently residing there, are usually sent by the physicians living in the same locality to mountainous regions, where they are apt to improve. Muscular rheumatism may disappear under the influence of hot sea-baths, but the damp air, always more or less present near the ocean, can have only an injurious effect on the malady. Women, however, suffering from any of the countless symptoms that their sex is specially liable to, invariably receive the greatest benefit from a sojourn at the coast. Some bronchial catarrhs, as also nasal catarrh, and most, if not all, varieties of scrofula, do nowhere better than near the ocean. For these the best time of the year is the hot summer months, while for convalescents and nervous cases spring and autumn are preferable for a sojourn at the shore. Renal and biliary calculi become worse.

With the selection of cases, however, not everything is done. The question remains, which of the many seashore places shall we select for our patients?

During the summer months it probably makes no difference where they go. But during spring, fall, and winter, great care must be exercised in the selection of a suitable dwelling. The reasons for this are the following:

During the height of the season there is no danger of malaria, but during the remaining part of the year there are but few seaside resorts, if any, perfectly free from this dangerous poison. Then there are many so-called winter hotels which do not possess the least preparations against the inclemency of the weather. In such buildings convalescents are apt to become chilled, and their complete recovery in consequence is retarded and often prevented. One of the most serious dangers, however, such patients are threatened with at most of these "health resorts" (?) is to be found in the utter neglect of sanitary precautions. I have met with, for instance, the following: In the immediate neighborhood of the house was a large pool of stagnant water. During the hottest season this pool was apt to be dry, but after a rain and during the rest of the year it was not only filled with water, but a quantity of green scum accumulated on its surface, and the effluvia, of a sickening odor, slowly but continually ascended and filled the bed-rooms of the house with a nauseous air. In winter the pool changed to a small lake. As soon as ice had formed of sufficient thickness in this lake, filled with rotten, stagnant water, it was cut and preserved in the ice house of the hotel, to be used by the summer guests for the purpose of cooling their drinking water!

At another place, also at the seashore and not far from Philadelphia, a large tank had been sunk into the ground for the accumulation of rain-water. That this tank was not fully water-tight, could be surmised from the moist condition of the surrounding ground. Twenty steps from it the manure from the stable was kept, and ten feet from it a gutter carried the waste-water from the kitchen to some empty lots further away.

In another locality, if possible, matters even were worse. A tank containing rain water was kept on the roof. In every story was a water-closet, the closets of all three stories communicated with each other, and the opening of the last was not ten feet away from the but partly covered water-tank. The water from the latter had a peculiar odor and taste slightly reminding the drinker of its neighborhood. Diarrhœa and dysenteria broke out (1881) amongst the inmates of the house; some of them were seriously ill. At my advice the water from the tank was used no more for drinking purposes, and as a natural con-

sequence the patients rapidly recovered and no fresh cases of disease occurred.

Certainly in all such cases it is the ignorance of the landlords that permits such a state of affairs. But ignorance here becomes a crime. That all such dangerous conditions may be avoided and that a perfect system of sanitary engineering can be applied to hotels, the following may be quoted in evidence: The Cape May Land Improvement Co. proposed to erect a hotel at Cape May Point, which was not only to serve as a "health resort" during the hot seasons, and as a safe place for guests during the cooler months, but which was also to be in the most perfect sanitary condition that knowledge and money could procure. The whole was left to Mr. A. H. Hamilton, their well-known manager, to execute. And what did he do? From the start he consulted a physician, an expert in such matters, Dr. Kirkpatrick, and besides he engaged the services of one of our best Sanitary Engineers, Gen. R. Thayer, that the laying and connection of sewer-pipes, the water supply, etc., might be directly under his personal supervision. It would lead us too far, in an article of this kind, to enumerate the elaborate and costly precautions which have been taken to secure to the "Cape-House" really perfect sanitary conditions. Special engines of over 100 horse power carry all sewerage far out into the sea; there is no possibility of any gases from the sewerage-pipes entering the building; and for drinking purposes only rain water is used, which is collected in large cedar-tanks and kept in continuous motion by a most ingenious mechanism. In every room there is an open grate and steam-heating; the gas is so arranged, that from the Argand burner no odor can escape into the room; all the windows are double and provided with inside shutters, and the verandah encircling the house is covered during inclement weather on all sides with glass, to prevent any harsh air from passing directly into the building. Special precautions have also been taken to avoid any odor from the kitchen ascending into the interior of the house, while the waste water at once leaves the sink and is carried by iron pipes a long distance away to a reservoir, where it is connected with the pumping-machinery and whence it descends into the sea. But not satisfied with all this, Mr. Hamilton, when everything was finished, invited many eminent members of the profession, especially those having made a special study of hygiene, to inspect the house and to criticise or suggest improvements. Where so many experts congregated, it was but natural for some corrections to be proposed, and all the alterations, then recommended, were at once made, or at least, if they needed a longer time for their execution, commenced while the medical visitors were still present. When wealthy companies thus endeavor to satisfy the just demands of modern medical science, praise should not be withheld. To-day the Cape House at Cape May Point stands there as the hotel with the most perfect sanitary arrangements of any house on the whole coast. Within its precincts it is an impossibility for anybody to contract an infectious disease, due to bad drainage, ventilation, or any other neglected hygienic conditions.

But if one building can secure this freedom from obnoxious gases, why should not others? The fault is often with physicians, for they ought not to permit their patients to go to any "health resort" for a shorter or longer sojourn, except they are convinced from personal inspection that the sanitary arrangements of the house are perfect. Whenever they find them deficient, they should draw the attention of the owner to this deficiency, and if not remedied, caution their patients against a residence at such a place. If this should invariably be done, how long would it take to insure to every hotel freedom from infectious air? For the want of this foresight many a patient has been sent to a premature grave.

In the same manner physicians ought be careful, during the cooler seasons of the year, not to allow their patients to visit the seashore, unless they stop at a real winter-hotel, *i. e.*, not only a house which is simply open all the year round, but one where special preparations have been made against cold weather. In such a building there should be double windows with inside shutters, open grate and steam-heating, and a verandah provided with tightly-closing windows all around. It is not enough to make a fire in a little stove and to give the patient an extra blanket, while the thin wooden walls and the shaky windows let the cold and damp air enter from all sides. The house must be heated all through, and this cannot be done with a few small stoves. Persons sent by physicians to the seashore are more or less ill; they have not the normal resistance of healthy individuals to harsh and suddenly changing weather.

If physicians would only insist upon a strict fulfillment of the demands of hygiene and sanitary science in every building recommended to their patients as a suitable residence at the seashore, a few years would see a mighty change. It is probable that many houses would have to be torn down, and that many a hotel-keeper would

have to seek another business to make a living; but our patients, when leaving their comforts at home with the view of obtaining vigor and health, would really achieve their object, and not return, as now frequently occurs, in a worse condition than that in which they left. Landlords ought to be made to feel that guests also have some rights, and that more is necessary for a "health resort" than nailing together a few boards, partitioning them off in as many rooms as possible, putting common deal furniture in, with a bed as hard as stone, and charging an exorbitant price for these "conveniences." Should physicians, however, act as suggested, and strongly recommend only houses where the advice of the profession has been adopted, all seaside hotels will really be what they ought to: Health Resorts.

Before sending, therefore, a patient to the seashore, we must first determine whether his condition is such as to be benefited by a sojourn there. Next, we judge whether the season is favorable for him. Finally, we ought to select a residence where he will not be exposed to any danger from bad drainage, etc., and if during spring, fall, and winter, where special preparations have been made against inclement weather. These precautions taken, physicians will not be disappointed in the results obtained; they may foretell their patients the great advantage which they will derive from the change of climate, and thus again one of the uncertainties will cease, which have brought medical advice—occasionally not without just cause—into disrepute.

CLINICAL MEDICINE.*

1. Rheumatism Terminating in Suppuration. 2. Constant Pain in Sacrum; Spermatorrhœa. 3. Post-Partum Hemorrhage. 4. Chronic Eczema of Face, Ears, Neck, and Ankles. 5. Syphilitic Iritis. 6. Asthma. 7. Inveterate Ozœna.

BY JAMES GUILD, M. D.,

Of Tuscaloosa, Alabama.

I hope to interest you with some desultory remarks in the narration of a few cases of recent date. The first two were unmistakably well marked cases of rheumatism, terminating in suppuration, a rare sequence of this disease. And they become peculiarly interesting in clinical medicine, for it is a maxim that pus is not one of the products of this disease.

Case 1. W. M., male, age eight years, with rheumatic diathesis, inherited from both parents —the father being a constant sufferer from a distorted body for a quarter of a century. June 3, 1884, this child was treated for acute rheumatic fever, accompanied subsequently with intense pain of the right thigh; the case was discharged on the 7th, the disease having terminated well. On the 28th of February, 1885, the child was again stricken down with what I considered as a fac simile attack of that of the preceding year, but it proved to be of a more stubborn type, as days, weeks, and months passed before final relief came; and in the interim the fever seemed at times entirely subdued under the usual rheumatic treatment; the right thigh, very painful but slightly swollen, became painless and flexible; this condition, but of short duration, occurred several times, to be succeeded by high fever with the usual accompaniments of intense pains, principally in the right thigh. At this stage of its obstinacy, the patient becoming much emaciated and feeble, the disease became metastatic in its nature, attacking the arms and sides, particularly the intercostal muscles. Dreading cardiac complication, remedies were addressed to this region with quick relief. One peculiar feature of the right leg complication was, that pain manifested itself persistently on the inner aspect, just above the knee, and I was apprehensive of coxalgia. This pain, centered in the obturator nerve (which sends a branch to the hip joint), is regarded of great diagnostic value in this disease, but developing no increase of pain by tapping the knee or by pressure on the trochanters, soon dispelled this idea. As soon as swelling became perceptible, poultices and fomentations were applied assiduously, with the view of resolving the inflammation; but finally a large collection of pus had to be liberated with the knife.

Case 2. O. B., age 40, a sufferer for twelve months with articular rheumatism of right knee, presented himself for treatment. The inflammation involved the muscular tissue of almost the entire limb. The treatment prescribed consisted of a combination of iodide of potash, salicylate of soda, tincture of cimicifuga, and gelseminum. Patient returned in three weeks, after having experienced decided alleviation of all the symptoms, having imprudently been at work on his farm and brought on a relapse of the articular swelling. Came to see me again on the 21st of May, with an issue directly over the inner aspect of the knee, discharging pus; the abscess had been opened by his family physician. The rheumatism in this case evinced the same erratic tendency as the other—developing itself by exposure at remote

* A paper read before the Medical Society of Tuscaloosa, Alabama, June 1, 1885.

parts of the body, which proved very tractable upon a renewal of his medicine.

There is an interesting feature in these two cases to which your attention is directed. Specially, viz.: the exceptional termination of rheumatism into suppuration. Regarded as a disease *sui generis*, for the reason that the most intense inflammatory swelling has resolved itself spontaneously, without so-called specific treatment, and leaving no perceptible results, it is generally conceded by the profession that rheumatic inflammation is never followed, *per se*, by suppuration. But as to this characteristic there is great discrepancy of opinion among our standard authors.

Elliotson writes unequivocally thus, "I mentioned before, when speaking of inflammation generally, that rheumatism does not terminate in suppuration. If suppuration occurs it must arise from another inflammation being present, or being excited by it." Mark, here is an admission that sometimes it is an accompaniment.

Watson says, "If suppuration sometimes occurs, it is because the rheumatic inflammation has extended to contiguous textures, and thus and there has run the ordinary course of inflammation. The inflammation of the synovial membrane may be of sufficient intensity to give rise to the formation of pus. When, however, the inflammation extends to the serous tissues within and around the heart, the products of the inflammation are just the same as when inflammation of the same textures of the common kind is anyhow produced." Dr. George B. Wood records the fact that, "in some instances, suppuration takes place in joints, destroying synovial membranes, and abscesses form in soft parts and discharge externally." Dr. S. D. Gross maintained that, "Sometimes large deposits of pus take place in the cellular tissue of the nates, or beneath the gluteal muscles, and are *commonly* the result of a rheumatic state of the system." It is an unquestioned fact, that the great majority of our inflammatory diseases are caused by sudden atmospheric changes.

In the army of Northern Virginia, during the late war, a newly recruited regiment was stationed at what was called High Bridge, to protect it from the enemy. The weather was not at all inclement, but these raw recruits not inured to the hardships of war, slept upon the cold ground without the proper protection. Soon their ranks were decimated by cerebro-spinal-meningitis. One of Gen. Lee's medical inspectors told me personally, that he saw a stout fellow walking about camp, a corpse in twenty-four hours; at the autopsy, pus was found all around the brain. This endemic was one of the phases of influenza, epidemic cold—really nothing but one of the protean forms of rheumatism.

Case 3. On the 3d of this month, O., age 27, short in stature, weighing 150 lbs., temperate, a moderate smoker, apparently a well preserved man, applied for relief of a constant pain in the sacrum, day and night, without any remission, there being no discomfort by pressure or by any motion of the body.

At once search was instituted for some remote cause for this reflex trouble. All the abdominal viscera seemed to be, functionally, in a perfect condition. Nocturnal seminal emissions occurred once or twice monthly. Admitting that he had prostituted himself a few years ago, even to lewdness, but was now virtuous and wanted to marry—finally an affirmative reply was given to the query, Do you ever perceive any involuntary discharge from the penis during defecation? This was a satisfactory clue to the real malady. His suffering was so intolerable, that he readily submitted to the proposed treatment with cold steel. Commencing with number six bougie (to be graduated), at the first insertion, the most exquisite pain was developed at the prostatic urethra, fully confirming the diagnosis. Having experienced decided relief, he returned promptly on the third day for treatment, and after this there was entire exemption from pain, so that one week elapsed before it was renewed. Upon a slight uneasiness recurring in the same region, he came back the third time, and since has returned at stated periods, and has obtained continued and complete relief. This treatment of a case of well marked spermatorrhœa surpassed my most sanguine expectations. The mechanical distension by the solid bougies, has so removed the vascular engorgement by virtue of its compression, and so obtunded the general sensibility of the delicate structures, that we can confidently promise a permanent cure. The bougie, when fairly introduced into the bladder, should remain in situ for at least thirty minutes. The above treatment I regard as the sheet-anchor in spermatorrhœa, as formerly stated to the Society when the subject was under discussion.

Case 4. Mrs. H., a tall, young, healthy and well developed woman, mother of two children, miscarried four or five weeks ago; was called to arrest uterine hemorrhage, which had continued unceasingly, baffling all treatment. With a correct appreciation of the real pathological condition, tincture of ergot was administered with the view of freeing the womb of any extraneous matter,

such as portions of membranes or placenta. This treatment was pursued diligently, giving teaspoonful doses every hour, until a portion of the placenta was extruded, affording an immediate stoppage of the hemorrhagic discharge. For more reasons than one, it should be the province of the accoucheur, to not only secure a firm contraction of the uterus, but to cleanse this viscus of all relics of labor that may become incarcerated, jeopardizing life either by hemorrhage or septicæmia. Most generally the offending matter, consisting of particles of membranes or placenta, will be found protruding from the os, and can be extricated by the finger; when not accessible to the finger, the curette should be brought into requisition. In the majority of labors, all women suffer more or less from its traumatisms. And if the abraded and lacerated surfaces are permitted to be constantly bathed in putrescent and fetid matter, the blood is liable to be infected with the most deadly septic poison. By observing the proper precaution, to wash out, purify and disinfect the uterus, I unhesitatingly lay down the aphorism, that no parturient woman should die from septic peritonitis.

Case 5. Miss M., young lady of robust constitution, has been afflicted four or five months with chronic eczema of the face, ears, neck and ankles; from its inveteracy and harassing pruritus by day and night, she had despaired of relief, when placed under my treatment a few weeks ago. After a thorough elimination of the morbid secretions (always present in this phase of the eruption), with proper alteratives, the skin was constantly lubricated with mild astringent ointments. Now, the sixteenth of a grain of tartar emetic was administered, as a direct alterative of the dermoid tissue, with the happiest effects; there was immediate improvement, continuing uninterruptedly to an ultimate cure.

Dermatology is probably the greatest bugbear to the general practitioner, and some medicinal agent of the character of a panacea, adapted to all obstinate exanthemata, would be welcomed as a great desideratum. The potency of tartar emetic in all inflammations of the mucous membranes is well attested, and it most assuredly exerts the same therapeutic effect upon skin diseases, and why not? Both being of the same anatomical structure, the mucous membrane is as it were a reflex of the skin.

Case 6. Negro girl, only 12 years of age, had been under treatment several months for iritis, with very slight benefit. The physical appearance of the eye indicating its specific character, was unmistakable—the natural black iris was now of reddish, dusky hue, the conjunctiva in its immediate vicinity smartly injected. This case was diagnosed at once as syphilitic, (not congenital, but acquired,) although no primary lesions were elicited on inquiry into its history. Upon the face minute papulæ were discoverable, and just under the lobule of one ear, found a well-marked pathognomonic blotch, syphilitic psoriasis.

Case 7. T. O., male, age 30, a broken down debauche, very intemperate for a number of years, was treated last winter for asthma of a grave type—being the first attack, there was unusual alarm. Immediate relief was obtained by correcting the morbid secretions, thereby eliminating disintegrated matter from the blood, the direct cause of the respiratory difficulty; and afterwards large doses of iodide potash were administered with the view of reducing enlargement of the liver. The prime cause of this man's trouble was alcoholism. He continued to drink, entailing upon himself its dire consequences, until this last month, when he was compelled to seek medical aid, being well nigh exhausted from his asthmatic trouble. The points of interest in this case are two-fold, its real pathology and the direct and indirect cause of the respiratory difficulty. First, the blood was poisoned by excessive accumulation of the albuminoids, consequent upon the feeble vitalization by the air, most of his oxygen being consumed by the alcohol. Although there were mucous rales all over the chest, simulating bronchitis, the air penetrated the lungs well, the patient labored hard for breath, not from dyspnœa, but apnœa; in fact the blood could not be oxygenated. Second, the direct cause was venous repletion, keeping up imminent suffocation, and indirectly prolonged by a weak heart, probably fatty degeneration, from profound alcoholism. But now, digitalis in large doses, by giving steady tonicity to the muscular heart, keeps up a healthy equilibrium of the respiratory functions.

Case 8. The mention of an inveterate case of ozæna, of twelve months' standing, will conclude this article. A few days ago I prescribed for this patient, a fine healthy-looking boy, a treatment that has never failed me in effecting lasting cures. He had been unsatisfactorily treated by a specialist of eminence, and though his trouble is complicated with enlarged tonsils, militating against treatment, his condition is much ameliorated at this date. I have found from experience with this loathsome disease, that the mode of administration is of equal importance with the remedy itself; that we can't reach the entire nasal passages, except by an atomizer, by means of

which our medicinal agents are brought in intimate contact, in the form of a spray, with all the angularities of this somewhat intricate avenue, both pleasant and inoffensive to the patient.

LIGATING THE UMBILICAL CORD.

BY E. T. BLACKWELL, M. D.,

Of Cedarville, N. J.

All the teachers through whom my obstetrical principles were formed protested against the heavy ligature, generally a cord made from twisted strands, or a piece of tape, which was apt to be handed to the practitioner to secure the funis after the birth of a child. Some one of them (Professor Hodge, I think), gave the classical description for preparing it, found in Ramsbotham's Midwifery (Philadelphia, 1847), p. 123: "The ligatures commonly employed in London consist of eight or ten pieces of thread, a skein of which is placed in readiness for our use. A sufficient number having been selected to form the proper thickness, a knot must be tied at each end; and this preparation should be made before the child is born. Even in forming the ligature some attention is requisite; if it be too thick, it will not compress the arteries sufficiently to prevent bleeding after the funis is cut; and it is also liable to lose its hold and slip altogether off the cord, thus leaving the vessels perfectly unprotected; and if, on the contrary, it is too thin— consisting of only two or three threads—it will probably cut through the membranes covering the cord, as well as the coats of the vessels themselves, and cause in this manner a loss of blood. It is also necessary that the threads should be all of equal length; for if one or two be shorter than the rest, they alone will make compression, and consequently they will act as though the ligature were composed of them only." Dewees says,* "The best ligature we can use, is part of a skein of fine thread, and passing it once around the cord and tying is sufficient."

I have carried out this instruction by taking of ordinary sewing cotton a length equal to the distance between the hands when the arms are widely outstretched—a little over a yard and a half—doubling it upon itself three times, making eight strands; drawing evenly and tightly, and making a knot in each end by slipping it about the extremity of the finger. Number 20 is sufficiently strong; but if a longer ligature is preferred, a coarser thread of six strands will be sufficient. A ligature of this kind cannot be broken by any force exerted through the hands, and if applied with the full strength and secured by a proper knot, cannot fail to occlude the vessels. If there be any oozing after the tying, it is significant that the full strength has not been exerted in drawing the ligature; or it has been allowed to slip. A second, applied with the precautions mentioned, has always availed, in my own experience, to produce perfect stoppage of the flow.

* Abridgment of Baudelocque's Midwifery, Phila., 1823.

HOSPITAL REPORTS.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

Gynecological Clinic of Prof. Wm. S. Stewart, A. M., M. D.

Reporte by JOHN S. STEWART, M. D.

Ruptured Perineum—Two Cases, in both of which Menses Appeared After Operation, without Unfavorable Results.

Case 1. Mrs. C., æt. 36 years, has been under treatment for some time. The following history is interesting, and will explain the nature of her case. Mrs. C. is the mother of five children, and until about five years ago enjoyed good health. At this time she had her fourth labor, and says that it was a very difficult one; that it was a breech presentation; that the forceps were applied, but that the child was finally taken away in pieces.

During this labor the perineal body was ruptured, or, to use a more common expression, "she was torn."

Unfortunately for her, the physician in attendance did not attempt to repair the damage, which could have been repaired with greater ease and less discomfort to her then than she will have in undergoing the secondary operation.

This took place five years ago; her recovery was rapid, and she suffered no inconvenience at that time. Two years later she gave birth to her last child, but this labor presented nothing remarkable so far as she knows, being no more difficult than an ordinary labor in a multipara.

A short time after her recovery she noticed that her abdomen was beginning to enlarge; this swelling or dropsy, as she called it, continued to increase month by month, until the abdomen was becoming uncomfortably large; the abdominal and respiratory organs were displaced, and the uterus (itself) gave way and became prolapsed.

When Prof. Stewart first saw her she had been in this condition one year. Examining, he discovered the uterus almost completely external to the vulva. But while the patient was upon her back the displaced organ could be returned and held in position with a slight effort of the hand. However, when she attempted to resume the erect posture the womb at once began to descend, and soon protruded as before. It was also discovered at this examination, when the womb was returned to its proper place within the pelvis, that there was an almost complete laceration of the perineum.

She had been told by several physicians that a tumor was growing within her, which was the cause of the abdominal enlargement; more than this she did not know. After a thorough and careful examination the tumor was found to be a

cystic development, possibly of the parovarium or some portion of the broad ligament; no fluid being drawn off and examined, a more certain diagnosis could not be made. The general health of the patient being good and her only inconvenience arising from the size of the swelling, with a view of confirming the result of the same treatment used a short time before in a similar case, the conservative method was adopted. This treatment consisted of ammonii chloridi gr.x, three times daily. In addition to this the uterus was replaced and supported by an inflated rubber disk, 3¾ inches in diameter; and while this was in position the womb did not descend. The patient was seen at intervals of a week or more for some months, the disk being each time removed and cleansed, while the other treatment was continued.

After one month the swelling was decidedly diminished; this decrease in size continued without intermission, and at the end of one year, the ammonium having been kept up all the time, there was no tumor to be found. The procidentia still occurred when the disk was removed, though not to the same extent as when the abdominal enlargement existed. This enlargement was undoubtedly the chief cause of the original displacement; but now, the uterine ligaments having been so long upon the stretch, the support which they should have afforded was entirely lost. In addition to this the laceration still existed, the parts being thus deprived of the natural support which they have when the perineum is intact. The patient having been thus far much relieved by the course of treatment adopted, and being anxious for any further relief which could be afforded, comes to the clinic with that object in view. The present examination reveals a prolapsus uteri and with it a decided prolapse of both the anterior and posterior vaginal walls. The laceration extends completely through the perineal body to the margin of the anus, the sides of the rent being lined with projections of cicatricial tissue, while in the posterior vaginal wall also are the evidences of an extensive tear.

The present complaint of the patient is that she feels a dragging sensation, accompanied by pains in and about the pelvis, her suffering varying according to the extent to which her womb is displaced. Having been previously advised to undergo an operation for the repair of the damaged perineum, and she having given her assent, the operation was begun. Ether was administered, and the patient having been placed in the lithotomy posture, a large soft sponge was introduced within the vagina to support the prolapsed uterus and put the vaginal walls upon the stretch: it answered this purpose admirably. Prof. Stewart then introduced the index and middle fingers of his left hand within the rectum; the parts were put upon the stretch in this way and a raw surface was quickly made with the curved scissors. In the paring process the ragged projections of scar tissue were removed and the venous hemorrhage which occurred was readily checked by an application of phenol-sodique. Quite a large surface having been denuded, the parts were brought together with wire sutures about one-half inch apart and passed carefully through the thin recto-vaginal septum and were secured with shot. This completed the operation, and as a result, a firm perineum could be felt. The patient was placed in bed having her knees firmly secured. Upon the fourth day after the operation, very much to the regret of the patient and her attendants, the menses made their appearance, being about ten days before the regular time. Strangely, but fortunately, no unfavorable results followed, the pain and soreness about the parts being exceedingly slight. On the eighth day after the operation the sutures were removed and the patient permitted to urinate, the catheter having been used twice daily since the operation. On the removal of the sutures the union was found to be perfect, a somewhat remarkable result after having been exposed more or less for three or four days to the irritating menstrual discharge; and in place of the great fissure which had existed, a firm and respectable union could be felt and seen. During the following day the patient was given an enema, but this having produced no effect, a mild laxative was used with success, causing slight pain at first, but this quickly disappeared. After this she left her bed, and four days later was discharged from the hospital feeling well, the parts being in good condition.

Case 2. Mrs. F., is a widow, 25 years of age. During her last confinement she was torn, and ever since that time has been suffering from occasional sharp abdominal pains and a constant bearing down. She comes to the clinic seeking relief, and is willing to submit to anything that it may be obtained. The patient was placed upon the table and an examination begun. The laceration was found to be quite extensive, especially in the posterior vaginal wall. The anterior wall was slightly prolapsed, and as a natural sequence the uterus was also prolapsed to a slight degree. With the exception of a slight hypertrophy of the cervix and vaginal wall, no other lesion could be discovered.

The indirect cause of her trouble was the laceration of the perineum and posterior vaginal wall, which deprived the anterior wall of its support, and this being no longer able to support itself, begins to descend and draws with it the attached womb, the displacement of which is the direct cause of her suffering.

An operation being thus clearly indicated as the most certain means of affording permanent relief, the patient was so advised, and not only consented to be operated upon, but was desirous that it be done at once. She was instructed to take a laxative that night when she went to bed, and to come back the following day prepared for the operation. When she returned she was etherized, and the operation performed as in the previous case. The hemorrhage was very slight, and after the surfaces had been carefully freshened the wire sutures were used and secured with shot. She was put in the hospital ward with the expectation that she would remain there until after her recovery, which would be about two weeks; but contrary to orders or expectations, she was taken home in a carriage in a few hours after the operation, and had the misfortune of her menses appearing on the fourth day; but under all unfavorable circumstances, on examining and removing the sutures, the union was found to be complete, and she made a very satisfactory recovery.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Stated meeting, August 3, 1885. President, Charles T. Parkes, M. D., in the chair.

Dr. Franklin H. Martin read a paper on the

Oleate of Manganese.

Saying: There is little doubt left in the minds of therapeutists in regard to the value of manganese as a remedy in certain forms of menstrual trouble. The remedy, in the form of permanganate of potash, was first brought to the attention of the profession by Ringer and Murrell, of London, in the spring of 1883. They recommended the drug in functional amenorrhœa. Soon after this he commenced experiments with the same preparation, and published the results in the *New York Medical Record*, September 29, 1883. To his knowledge, that was the first time that anything on the subject was published in this country.

In the course of his experiments, acting on the theory that the drug produced menstruation by stimulating the menstrual organs, he was induced to give the remedy in menorrhagia and metrorrhagia dependent upon an *atonic* condition of the organ. He found to his gratification that it acted equally well in these conditions, as in the opposite. He has also obtained good results from its administration in irregularities incident to approaching menopause. He has received very gratifying letters from many members of the profession throughout the country, who have used the drug in one or more of the conditions mentioned above, with good results.

Dr. Thomas, of New York, says of the remedy: "I think it is the best emmenagogue which has yet been discovered."

Dr. Roberts Bartholow not only recognizes its power as a remedial agent in amenorrhœa, but also considers it a general stimulant, making it equally efficacious in other menstrual difficulties dependent upon an *atonic* condition.

After publishing his second report on this subject, the author received a letter from Sydney Ringer, of London, in which he expressed his gratification at the result of his experiments, and in which he said:

"Like you, I have found the permanganate most useful in atonic conditions," and further remarked, "I was quite prepared to learn that the permanganate is useful in menorrhagia."

Since there is no longer any doubt about the great value of this drug in the distressing menstrual difficulties, the next formidable problem for the therapeutist to solve is, How shall it be administered? The permanganate of potash, the original preparation used for experiments and administration, in any form is liable to act as an irritant to the stomach. It has in many ingenious ways been made into pills, but as these pills must of necessity have for their basis kaolin, or some other inorganic substance, the drug in this form is not satisfactorily absorbed. The compound tablets of Wyeth & Bros., and other druggists, are objectionable, in many cases of irritable stomach, because the irritating undiluted drug comes in direct contact with its mucous membrane. On account of the many difficulties of administration, therefore, this valuable remedy has not met with the reception that is its due. Following the suggestion of Dr. Lewis L. McArthur, of this city, he succeeded in having an oleate of manganese prepared. This oleate was made for him by Edward Kreyssler, of the firm of Forsyth & Schmid, of Chicago. He says he is indebted to Mr. Kreyssler for the following statement of the *mode of preparation and of the physical and chemical properties of the oleate of manganese:* A solution of sulphate of manganese was made in distilled water, and to it a solution of sodium oleate was added. On mixing these two solutions gradually, and with constant stirring, a precipitate of oleate of manganese resulted. This precipitate, upon heating, changed to a putty-like mass. This was washed several times with warm distilled water, to remove the sodium sulphate, and the resulting mass was the pure oleate of manganese. It is of a light gray color, having a pinkish hue, of a sweet musty taste, and peculiar clay-like odor. It is sparingly soluble in alcohol, soluble in ether, chloroform, olive oil, and oleic acid.

The Method of Application.—He recommends that one drachm of a twenty per cent. solution of the oleate of manganese in oleic acid be applied to the abdomen of the patient, and its absorption promoted by friction with the hand.

In amenorrhœa it should be applied, if possible, every night for a week preceding the expected menstrual period, or at the time menstruation is due, and until it makes its appearance. In menorrhagia or metrorrhagia it, should be applied in smaller quantities, every night, until the desired effect is produced.

Of about a dozen cases in which the oleate has been prescribed by him, but four had reported. The success in these four was all that could be wished. Three of the four were cases of *atonic amenorrhœa*, the fourth, irregularity due to approaching menopause.

In the discussion Dr. Etheridge thought much advance would be made in the use of drugs if we were more careful to discover in what conditions they were beneficial. He had found this remedy useful in cases of atonic amenorrhœa, with the uterus in its normal position. He had found the aqueous solution an eligible preparation, and had also used it in the form of a suppository.

Dr. E. J. Doering said he had used this remedy in some cases of atonic amenorrhœa with good results. He asked the effect of the drug upon the pregnant uterus.

Dr. Paoli had used manganese somewhat for several years, in cases of menstrual disorder, with varying degrees of success. It was a useful remedy in many skin diseases. He had not used the oleate, and could not see how it acted upon the uterus, unless, possibly, by being applied at once after being freshly prepared.

Dr. Martin closed the discussion by saying he had used the aqueous solution in very small doses, also had had the remedy put in dry papers and swallowed with a glass of water. He had never used it in the form of a suppository. Manganese has no effect on the pregnant uterus. The drug seems to act as a general stimulant to the uterus, causing it to perform its normal function. It might be absorbed as the oleate and so produce its effects.

Does the Use of Tobacco Injure Sight? was the subject of a paper read by W. Franklin Coleman, M. D. The question was answered affirmatively by the author.

In the discussion Dr. Paoli said while the excessive indulgence in tobacco might be harmful, the fact of its almost universal use and continued use in many cases for years resulting in no deleterious effects, would seem to show that its narcotic power, used in the ordinary way, was very slight. He had used tobacco for fifty-five years and felt no ill results. The Germans use large quantities of it, and do not suffer. This seemed to be a case of excess of zeal on the part of the ophthalmologists to discover a cause for amaurosis. We ought to be conservative on this point.

Dr. Coleman closed by saying that only in certain susceptible conditions was tobacco liable to cause disorders of vision. But that so few suffered was no proof that it had not this baneful influence when acting with other causes.

Laceration of the Cervix Uteri.

Dr. John Bartlett read a paper in which he said his object in addressing the Society was to suggest a way and a time in which laceration of the cervix uteri may be easily and certainly detected soon after its occurrence.

Directly after delivery, if the fingers be introduced deeply into the vagina up to the contracted os uteri internum, and then carried in any direction a little outwardly, the flabby and floating ring formed by the non-contracted cervix may be felt, as Guillemeau described it three hundred years ago, "like a section of large intestine."

By very carefully following the entire circumference of this ring an existing rent may be discovered. But this examination is attended with some difficulties. The patient is exhausted with her labor, and fatigued with attentions, and just now, since "it is all over," longing for rest. She is impatient of, and perturbed by this *post factum* inquiry. Her state of mind, and possible expression of complaint, are apt to render an examination, which the physician cannot regard as absolutely necessary, less exact and thorough than it would be otherwise. And then, the soft and floating margins of the cervix have often somewhat of an intangible feel, if the expression be permitted, gliding past the finger like a detached clot of blood, and occasionally, in some portion of their circumference, passing out of satisfactory reach.

On this account it is not surprising to hear an obstetrician say that he cannot tell whether the post partum cervix is lacerated or not. The error of the accoucheurs who fail to recognize such a condition is, that they do not make their observation of the suspected cervix at the proper time. They examine the neck actually, as has just been done mentally—after the clearance of the uterus. The favorable moment for the examination—and that he said was the special point of his remarks—is just as the placenta is beginning to occupy and distend the cervix. The collar of flesh is then not floating and uncertain in feel, but stretched and expanded, forming a distinct ring, easily followed in its entire circumference. At this moment then, just as the cervical tube is being rendered tense by the placental mass, any laceration in it may be detected with ease and certainty.

Dr. Etheridge asked the author of the paper whether he had verified a case by speculum examination after discovering it in the way he had illustrated in his remarks.

Dr. Parkes said he had great difficulty in detecting laceration after delivery, on account of the relaxed condition of the parts. He thought the suggestion of Dr. Bartlett as to the way to obviate this difficulty was a good one.

Dr. Doering inquired as to the size of lacerations he had found.

Dr. Bartlett concluded by saying that he had verified cases of laceration discovered in the manner proposed by him. The largest laceration he had found was one and-a half inches in length, and the end of the little finger could be passed into it. In one case he encountered considerable hemorrhage from such a rent: and this may be the cause of continuous loss of blood when the os is well contracted.

Dr. Bartlett illustrated his remarks with earthen-ware models, turned by a potter, under his immediate direction.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Occurrence of Blood in the Urine in Granular Kidney.

Dr. Samuel West thus writes in the *Lancet*, July 18:

Blood in the urine in granular kidney is not, I believe, of very common occurrence, and may on that account lead to difficulties of diagnosis. It may be in sufficient quantity to give the urine a bright-red color, or, as is less rare, a smoky or pinkish hue. The following cases have recently come under my observation:

Case 1. A girl, aged twenty-one, came into the hospital with a history of fits for two years, attended with attacks of biliousness, giddiness, and sickness. She had suffered from childhood with a chronic discharge from the ear, and her hearing was considerably impaired. For the last few weeks she had to rise several times in the night to pass urine. On the evening of her admission she had one of the so called fits. She did not lose consciousness, but became very excited, throwing herself about and complaining greatly of her head, sobbing and crying from the pain. She had severe retching, and pain in the cardiac region, and during the attack seemed to be in a

condition of great general hyperæsthesia. Her eyes were examined, and double optic neuritis discovered, with abundant hæmorrhages, many recent, and with glistening white patches. The case had presented itself at first as one of intracranial disease—possibly, it was supposed, an abscess connected with the old ear mischief. But the eye changes, the condition of the arteries (thickened) and of the heart (hypertrophied), associated with the presence of albumen in the urine, led to the diagnosis rather of granular kidney. The day after admission the urine was of a bright red color, and contained much recent blood. The albumen was abundant, about one-fourth, but the presence of blood made it difficult to estimate the exact quantity. The urine continued to contain much blood for sixteen days, when it disappeared and the color became normal, and then the urine contained one-third albumen. During this time the patient had had several of the "attacks" described, and for three days had severe epistaxis. The hæmorrhages, also, in the retina increased in number and size. Shortly afterwards a systolic cardiac murmur, thought to be hæmic, was detected. The patient's condition did not materially change during the next two months, except that she became by degrees profoundly anæmic, and as this developed she began more and more to complain of cardiac pain and dyspnœa. Two months after her admission she had another attack of epistaxis, and a few days later some small purpuric spots appeared on the backs of the hands and legs which had been for some days slightly œdematous. She now became very noisy and delirious, and continued in this state till her death, which took place about ten weeks after admission. There had been no return of blood in her urine. The post mortem examination disclosed the typical lesion of well marked granular kidney. The kidneys were greatly contracted. The left weighed only three ounces, and the right was converted into a small fibrous capsule, with hardly any trace of kidney substance remaining. It measured an inch and a half by three-quarters of an inch. The arteries and veins on this side were also much smaller than on the opposite. No obstruction existed in the course of the ureters, the bladder was healthy, and there was no trace of calculus either in kidney or bladder. The heart was hypertrophied and weighed 15½ oz., a very large size for so small and slenderly built a young woman, for her weight could hardly have been more than 6 st. The arteries were much thickened. The brain was œdematous, but otherwise quite healthy. The case was, therefore, one of well-marked granular disease of the kidney.

Case 2. Another case I have met with recently, viz., that of a young man of nineteen, a warehouseman, who believed himself to be in good health until three months before admission, when he suffered from hemorrhage from the bowels, and was confined to bed for five weeks. He seemed to get well, and remained in his usual health until two days before admission (Jan. 14). He then had a sore throat, and felt sore all over, and in the evening he noticed that his urine was very dark-colored. He had a little pain in the back, and during the night felt hot, then shivered and perspired. There was no history of chill or of any cause for the attack. The patient was pale and of a pasty complexion, with slight herpes on the lips. The right tonsil was slightly lacerated. There was no œdema anywhere. The urine was porter-colored, acid, sp. gr. 1014, and contained one-quarter of albumen. The arteries were thickened and the tension raised. The microscopical examination of the urine showed the presence of numerous red blood cells, with triple phosphate crystals and a few fragmentary granular casts. The quantity of urine passed was on the average above normal. The temperature on admission was 101°, but it fell the next day to normal, and remained normal afterwards. The throat affection rapidly disappeared, so that the rise of temperature depended probably upon this condition. Œdema was completely absent. The urine contained blood for a week after admission, and continued to contain albumen, though only a very faint trace, until his discharge nearly three months later. The history of recent sore throat, with albumen and blood in the urine, led me to think at first that the case was probably one of diphtheria associated with nephritis; but the condition of the arteries, the long persistence of albumen, and the absence of œdema, convinced me later that the case was one of granular kidney. This conclusion was confirmed by the subsequent course of the case, for the urine for the last two months of his stay was characteristic, being large in quantity (80-100 ounces), of low specific gravity, and with but a trace of albumen.

Case 3. Edw. P——, aged thirty-four, was admitted into the Royal Free Hospital as a case of acute nephritis. He had been a free liver and had drunk much beer, but was in good health until one month before admission. Then his legs swelled, and a fortnight later his toes also. On admission there was slight general œdema. The urine was reduced in quantity and contained one-half albumen with granular casts, and was smoky. The eyes were normal on ophthalmoscopic examination. The arteries were slightly thicker than normal for his age. The case ran the ordinary though protracted course of acute nephritis, ending in convalescence. On several occasions while the œdema persisted the urine contained blood, being sometimes bright-red in color, at other times only smoky. These alterations could not be traced to any cause, for they occurred during the time that the patient was kept entirely in bed. After about two months the œdema completely disappeared, and continued absent till the patient's discharge from the hospital. The albumen was at times completely absent, and at most times there was only a trace; and on several occasions after the œdema had gone the blood returned in the urine, generally to the extent of giving it a smoky tint, but occasionally the color was bright-red. Generally at these times there was an increase also in the amount of albumen over and above what the blood would account for. The duration of these attacks was about two or three days, during which there was no other change in the patient's condition. The arteries, however, were distinctly thicker and harder on leaving the hospital than they were on admission. I was led to regard the case as one probably of old granular change, with an intercurrent attack of acute nephritis. At any rate,

at the time of leaving, the case presented the characteristic features of granular kidney.

Since this case I have also seen several others of a similar kind, in which the diagnosis of granular kidney seemed clear, and during the course of which the urine on many occasions contained blood, sometimes only sufficient to give it the smoky tint for a few days, but at others sufficient to make it bright-red in color. It is not easy to determine the part of the urinary tract from which the hemorrhage comes. In the second and third cases it was, in all probability, from the kidney; but in the first the very bright color and quantity of the blood seemed to suggest its origin from the lower part of the urinary tract. The quantity in this case was so large as to suggest even calculus, but none was present. The difficulty in diagnosis between this condition and calculus has actually occurred, as in a case related to me by Dr. Sharkey, of St. Thomas's Hospital. The patient, a young girl, passed so much blood with the urine that the bladder was sounded, and, failing to find a stone, dilatation of the urethra and digital exploration of the bladder was suggested. To this Dr. Sharkey did not, for good reasons, consent; and the patient dying, no stone was discovered on the autopsy, but markedly granular kidneys.

In less severe forms the chief difficulty in diagnosis is from cases of acute nephritis. The second and third patients both had, during the latter part of their illness, a considerable amount of albumen in the urine, and as on most occasions the urine was smoky, and not often bright-pink in color, and also contained a few casts, the diagnosis of acute nephritis was natural, but they presented these points of difference from ordinary acute nephritis: (1) The absence in one case and the existing small amount in the other of general œdema; (2) the great fluctuation in the amount of blood and albumen at different times; (3) the subseqent course of the cases, the diagnosis of granular kidney becoming clear as they progressed.

The hæmorrhage which takes place from some part of the urinary tract in these cases of granular kidney, though uncommon, is not peculiar, except so far as regards its source. The explanation is probably the same as must be given to the hæmorrhage, which occurs from other parts in this disease. Epistaxis, often very severe and difficult to control, is one of the commoner epiphenomena. The first case suffered severely from it on several occasions, and once at the same time that the urine also contained blood. Of hæmorrhage from the respiratory tract in granular kidney I know nothing; but bleeding occurs occasionally from the bowels. The first symptom of illness in the second case was such a hæmorrhage from the bowels, which confined the patient for five weeks to bed; and although the cause of this hæmorrhage is not certain, its association is at any rate suggestive. Hæmorrhage into the eye and brain are among the commonest of incidents in the course of granular kidney, so much so that retinal hæmorrhages are of recognized diagnostic value, while brain hæmorrhages explain the apoplexy with which such cases not rarely terminate, and in both organs miliary aneurisms are frequently found. In the cases in which the hæmorrhage occurs actually in the kidney it is possible that there is another explanation. It may prove to take place especially in those cases of granular kidney in which the cirrhotic change is most marked round the Malpighian bodies, and the bleeding may then possibly be the result of the mechanical obstruction to the circulation in the Malpighian tufts. But I know of no observations bearing on this point. On the whole, however, we may with greater probability regard the hæmorrhage from the urinary tract as part of the general vascular changes which occur in this disease, and, if so, it is remarkable that hæmaturia is not of more frequent occurrence in granular kidney than it appears to be.

A Case of Urethrocele.

Mr. Skene Keith thus writes in the *Edinburgh Med. Jour.*, July, 1885;

A description of the following case will be of interest, in the first place, because the condition is not described in any book in the English language, with the exception of that of Dr. Skene on "Diseases of the Bladder and Urethra," nor have there been more than two or three cases recorded in British medical periodicals, and besides, the patient whose case I am about to narrate was seen by several members of this, and also of the Obstetrical Society of London, and none of these gentlemen had evidently seen such a case before. I had been present when Dr. Thomas operated on an almost indentical case in New York, and having this experience, the diagnosis of the case operated on by Dr. Keith was evident almost at a glance.

Mrs. S., aged 44, a big, stout lady, had been married at 22. She had two children at intervals of sixteen months, and for six years after the birth of the last was perfectly well. In 1872, after the birth of another child, she was annoyed by the occasional involuntary passage of her water when she coughed or sneezed. A son was born in 1874, another in 1875, delivered with forceps, another in 1877, and the last in 1879. All the children had very large heads. From 1872 until she became pregnant with the last, the urinary trouble continued to get worse, and Mrs. S. had often to get up in the night to pass water. During the whole of the last pregnancy, and ever since, the patient's condition was most lamentable. The uterus could only be kept inside the vagina by a large ring pessary; there was constant pelvic pain, and for a period, extending over more than four years, there had never been one night in which she had not been compelled to get up to empty the bladder at least five times, and usually much oftener. During the day she considered that she was fairly well if she did not have to micturate oftener than once every hour. For a long time there had been some pus and blood mixed with the urine.

In April of last year, Mrs. S. consulted Dr. Keith, and the local condition was found to be as follows: There was no perinæum; the uterus was large, and the os came down to the introitus vaginæ whenever the ring pessary was taken out; the wall of the urethra was enormously thickened, and projected considerably downwards. The base of the bladder was felt to be quite healthy. The passage of a catheter caused severe pain, and before its point entered the bladder some thick pus flowed from it. The urine was

quite clear. The skin surrounding the vulva was red and sore, for although patient was most particular, and washed and dried the parts many times a day, a little pus, constantly oozing from the orifice of the urethra, kept the skin moist and irritated. Dr. Keith considered that the condition of the urethra was possibly due to its posterior wall having been pressed outwards by the large heads of the children, and as this condition was kept up by the loss of support due to the absence of all trace of a perinæum, he thought that it would be best to make a large, firm perineal body, which would press the dilated urethra upwards and forwards, and thus obliterate the pouch, which was constantly full of pus. The perinæum was repaired in April, but did not do what was expected. It simply supported the uterus, and took away a good deal of the pelvic pain. It became evident that the urethra itself would have to be attacked. Dr. Keith cut down, in the middle line, on a sound which had been passed into the bottom of the pouch, and made a large opening into the urethra. The wall was fully $1\frac{1}{4}$ inches thick, and the opening was made large enough to admit one finger easily. A large amount of pus came away when the incision was made. The lining membrane of the urethra was rough and of a dark purplish color. The mucous membrane of the urethra and vagina were sewed together to prevent too rapid closing of the wound. There was not a very great amount of hæmorrhage. From the first night patient became more comfortable; of course control over the bladder was not lost, as the incision did not reach back to the neck.

After four months, all pus and irritation having disappeared, the opening into the urethra, which, in spite of the original stitching together of the mucous membranes, was hardly larger than the point of an ordinary catheter, was closed with twelve horse hair sutures. The patient got up on the day after the operation. The stitches were removed on the ninth day, and she now sleeps the whole night through without having to get up, and during the day requires to micturate two or three times only. In addition, all pain is now gone.

There was not the slighest doubt that the urethra alone was diseased and prolapsed. When the uterus was not supported by a pessary, and lay almost outside the vagina, there was naturally some lowering of the bladder, but there was no condition at all approaching to cystocele; and when the uterus was properly supported, the slight sinking of the bladder was removed. This did not, however, have the smallest effect on the swelling of the urethra. That remained, no matter what the position of the other pelvic viscera was. Direct pressure lessened the size of the swelling slightly by emptying the pouch. In most of the cases which have been operated upon, an oval piece of the urethra has been cut out, and the parts stitched together at once. When the lining membrane of the urethra has not become diseased, this is, without doubt, the proper method to adopt. In a case such as that of Mrs. S., such a plan would probably not have been successful. By making a dependent opening, and thus preventing the retention of pus and ammoniacal urine, the urethra soon returned to its normal healthy condition, in the same way as a diseased bladder will become healthy after a vesico-vaginal fistula has been properly made to cure cystitis, the only difference being that a patient with an opening in the base of her bladder is always uncomfortable and disagreeable to her friends. With an opening into the urethra she is uncomfortable only when making water, as the labia minora are then not in a position to perform "the most modest of the uses ascribed to them."

A Case of Diabetes Mellitus Cured by Removal of the Uterine Appendages.

Dr. Francis Imlach thus writes in the *Brit. Med. Jour.*, July 11, 1885:

K. G., a widow, aged 31, consulted me on February 12, 1885, on account of leucorrhœa and pelvic pain. A diagnosis of pyosalpinx was made out; and, as she seemed ill and wasted, operative treatment was suggested. On the 22d, she mentioned that for a month she had been afflicted with insatiable thirst and sleeplessness; that the bowels were habitually constipated, and the urine greatly increased in quantity. On testing a sample of urine, of specific gravity 1036, no albumen was found; but, on boiling with Fehling's solution, it became evident that she was passing sugar. Menstruation was regular, and, though painful, not profuse. All thoughts of operation were abandoned. She undertook to live upon gluten bread and biscuits, fish, meat, and buttermilk; to give up starchy food and sugar, and as much as possible to restrict her drink. Soap and water enemata were ordered, and bromide of ammonium prescribed for the sleeplessness. Under this treatment the urine became reduced (from an unknown quantity) to five or six pints per diem; but, when samples were tested with Fehling's solution and by the differential density method, there was little diminution in the sugar. On March 16, three minims thrice daily of Clemens's solution of arseniate of bromine were substituted for the bromide of ammonium; and, a fortnight later, the dose was increased to ten minims; but, roughly estimated, the excretion of sugar continued unaltered. On April 15, she passed 2,560 grains in twenty-four hours. As she was becoming rapidly weaker and more emaciated, she was admitted into hospital on May 15, where the antidiabetic diet was strictly maintained. On May 16, 1,200 grains of sugar were excreted. On May 19, the uterine appendages were removed. The right Fallopian tube was thickened in its walls, occluded at both ends, and distended with pus. The left tube was thickened, but not occluded at its fimbriated extremity, and contained only a little muco-pus. Both ovaries were so firmly adherent in the pelvis, that their removal was somewhat difficult. The fundus of the uterus, which was bound by dense adhesions to the sacrum, was liberated. The patient recovered without a bad symptom, and with a surprisingly level temperature chart. She got out of bed on the ninth day, and left hospital on June 3d. Unfortunately, I am unable to add a complete account of the urine passed subsequent to the operation, as, through an error, no quantitative measurements of the sugar were made. During the first twenty-four hours, between six and eight ounces of urine con-

taining sugar were drawn off every six hours. The specific gravity during the first six hours was 1028, next it fell to 1014, and then rose to 1034.

Date	Ounces of Urine in 24 hours	Specific Gravity	Sugar	Diet

" 31	24	1022	"	"
June 1	24	1020	"	"
" 2	18	1024	"	"

The sugar, tested daily with Fehling's solution, gradually diminished until May 26th, when it finally disappeared. On June 12th, the urine was normal, and of specific gravity 1020. For a week previously she had been at home on ordinary fare, except that she took no rice pudding, and put no sugar in her tea. She then took rice pudding daily, with unlimited sugar, until June 19th, when the specific gravity of the urine was 1010, and not a trace of sugar could be detected. There is no longer constipation, and her strength is already almost completely restored.

Glycosuria being persistent under antidiabetic regimen, and the health worse, operation was offered as a forlorn hope. Sir J. Paget makes no allusion to diabetes mellitus among "the various risks of operations;" but Dr. Dickinson, in his able work on the subject, says that "surgery is attended with unusual danger;" and Dr. Wm. Roberts states that "operations for diabetic cataract generally fail from uncontrollable suppuration of the eyeball." Beyond this element of danger, there was the fear lest the operation should do no good. Diabetes and pyosalpinx are not known in association. The patient was married ten years previously, had a still born child a year later, and became a widow two years before I saw her. As the pelvic pain was of indefinite origin, the pyosalpinx was probably of ancient date, whereas the diabetic symptoms were recent. Still, there remained the possibility that removal of the suppurating tubes might cure the disease. There was a further argument: the younger the person, the less hope of ultimate recovery from diabetes. "The development and exercise of the sexual functions," says Dr. Wm. Roberts (*Renal Diseases*, 4th ed., p. 256), "appear to have a marked effect in increasing the liability to diabetes in both sexes; and the diminished frequency of the disease in women after the age of 45 (as compared with men) corresponds with the earlier decline of sexual activity in the female sex." And, not only is diabetes less frequent among women after 45; it is also less acute, and does not kill nearly so quickly. By induction of the menopause, it was hoped that the acute diabetes might become chronic.

Albuminuria and the Mercurial Treatment of Syphilis.

In the *Med. News*, July 19, we read that at the recent Congress of German Physicians, Fürbringer, of Jena, read a paper upon the albuminuria of syphilis with and without mercurial treatment. He found that of secondary syphilitics who before treatment were not albuminuric, eight per cent. became albuminuric during treatment. In cases of primary syphilis not treated with mercury, albuminuria occurred in twelve per cent. of cases, almost always in the stage of disappearance of roseola; with the exception of three cases, the albuminuria disappeared with the institution of mercurial treatment.

In the discussion which followed, Schuster claimed that cases of serious albuminuria due to syphilitic renal disease recover by mercurial treatment, and that there is no contra-indication to the use of mercury in these cases.

Schumacher had observed several cases of simultaneous syphilis and nephritis, and was satisfied that the nephritis preceded the syphilis and continued during the further development of syphilitic phenomena. The mercurial treatment used in these cases did not aggravate the symptoms of nephritis.

In his quite recent work on *Urinary and Renal Disorders*, Dr. Beale says, "of all the forms of chronic renal disease, those which are due to syphilis are the most likely to get well." Even in large albuminurias, with considerable and persistent dropsy, improvement may be confidently predicted, and even recovery not uncommonly takes place in the course of a few months.

The treatment in the early stages is that usual for Bright's disease—purgatives, warm baths, and hot-air baths. When the albumen is reduced to one-fifth and urine is passed freely, he recommends iodide of potassium, iodide of iron, and other preparations containing iodine. Complete recovery is often thus produced after judicious treatment is kept up steadily for two or three months.

Dr. Beale thinks that the glandular enlargements, of which the kidney is an example, in syphilis, were less common when the mercurial treatment was more in vogue, although he admits that necrosis is less frequent. There can be no doubt that the judicious combination of the alterative with tonic chalybeate treatment in syphilis, as contrasted with expectant treatment, is calculated to be most serviceable.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——An address in which the thoughts are worth attentive consideration is that of Dr. Conrad George, of Ann Arbor. His subject is "The Duty of the State Towards the Medical Profession," and he maintains that the time has come for the legislatures of this country to put a stop to the further

creation of medical colleges, and to keep them all under State patronage and State control.

——"Voice in Singers" is the title of a pamphlet by Dr. Carl H. von Klein, of Dayton, Ohio. He claims that the superiority of Italian singers is owing to the peculiar mode of training and teaching there in vogue. Being a German, we judge, he is not willing to ascribe it to the Italian language. We observe, he says, Adelina Patti was born in Spain. Philadelphians maintain that the celebrated *diva* first saw the light in Powell street, in their city. (Price 25 cents, Hann & Adair, Columbus, Ohio.)

——In a reprint from the Liverpool *Medico-Chirurgical Journal*, Mr. Reginald Harrison, F. R. C. S., describes, with eight illustrations, some changes in form of the prostate and floor of the bladder, which are liable to take place with advancing age, and which are of surgical importance.

——The Seventeeth Annual Report of the Inebriates' Home, Fort Hamilton, New York, contains the statistics for the year, and some general observations from which we learn that about one-third of the cases in such institutions are restored (permanently?).

——The Fifth Biennial Report of State Lunatic Asylum No. 2, Missouri, argues in favor of large asylum buildings, on the ground that the insane can be thus better cared for and more cheaply. The cheapness we grant, but the better treatment we very much doubt.

——The Annual Report of Births, Marriages and Deaths in the City of Providence for 1884 is prepared with customary accuracy by Dr. Edwin M. Snow. Among other interesting facts he notes the large decrease in deaths from consumption since 1855. For fifteen years previous to that date the deaths from that disease were annually 1 in 210 inhabitants; since that date only 1 in 313. Whether this marked difference is real or only apparent (arising from a different classification) is not clear.

——Dr. C. H. Hughes, editor of the *Alienist and Neurologist*, has issued in pamphlet form a number of editorials from that journal. They are on popular topics.

——The subject of cholera infantum is discussed by Dr. W. P. Watson, of Jersey City, in a pamphlet before us. In treatment he trusts rather to diet and nursing than drugs, and especially condemns opiates.

——A review of the germ theory of disease, in its relations to sanitation, is the topic of a paper by Dr. P. C. Barker, of Morristown, N. J. It will be found a well-prepared summary of the subject.

——In an interesting reprint, Dr. A. Van der Veer, of Albany, describes Mr. Lawson Taits' method of operating for ovarian tumor, and reprints five cases of abdominal section by himself on the same plan.

BOOK NOTICES.

A Treatise on Epidemic Cholera and Allied Diseases. By A. B. Palmer, M. D., LL.D., etc. Cloth, 8vo., pp. 222. Register Publishing House, Ann Arbor, Mich. Price, $1.00.

The extended reputation of the author, and his long experience as a teacher, practitioner and writer, will no doubt secure to this volume a considerable share of the sale of monographs on the dreaded Asiatic pest which for two summers has threatened us. Compared with the treatises on the disease heretofore noticed in these columns, Prof. Palmer's work is more extended, and his views are conservative and cautious. They are such as are endorsed by the good sense of the profession in general, and are safe. Of course, neither he nor any honest and intelligent physician pretends to cope successfully with the more malignant forms of the disease, when once they have seized upon the frame; but in measures of prevention and precaution there is a wide field for fruitful exertion, which is clearly laid down.

Inebriism, a Pathological and Psychological Study. By T. L. Wright, M. D. 8vo., Pp. 222. Wm. G. Hubbard, Columbus, Ohio.

This is not a calm and scientific discussion of the effects of alcoholic beverages on the human system, but a tirade against drunkenness. Even in this light, it is exaggerated and extreme in language. Much, therefore, that is good in the book will fail of its effect through the evident intolerance that mars many of its pages. There is a prevailing lack of diagnosis between alcoholism itself, and alcoholism merely as a symptom of an impaired mental condition, or an inherited or acquired neurotic dyscrasia. This is universal in popular harangues on the subject, but we have a right to look for something better in a medical treatise. Such an omission must necessarily place the work on a lower level of merit than one would wish to see it.

—One of the most prominent physicians of Indianapolis, on his return from a summer vacation of three weeks, was met by the leading undertaker, who said: "Ah, doctor, so glad to see you safe back; we have missed you so much."

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE CHINESE PROBLEM.

In publishing the description of Chinatown in San Francisco some weeks ago, we would not have it understood that we sympathize with the party who would strictly prevent the ingress of Mongolians into this country. Any such position is a virtual acknowledgment that Christianity, civilization, and free government are unable to cope with the social problems of the day, and must have recourse to the effete policy of seclusion and non-intercourse in order to maintain their existence in the struggle for life and the conflict of ideas. If we entertained any such belief, we should rather accept the Mongolian religions than Christianity, and their civilization than ours.

The exclusion of the Chinese from our shores is a gross violation of the letter and the spirit of that "Declaration of Independence" which we have been taught to regard as the *Magna Charta* of American liberties. That we should draw a line against the poor laborers of any race, nation, or color, is a contradiction of the fundamental doctrine of our social compact, and is a blot on our boasted position as the haven for the afflicted and down-trodden of all nations. It is prompted by no noble or exalted motive, but by a mean spirit of jealousy, or by a cowardice born of a lack of faith in the principles we profess.

That their morality is low, that they do not intend to become citizens, that they do not look upon this country as a permanent abiding place —all this may be true of the Mongolians, and we believe it is. But who are we, to make much of this mote in the eye of our neighbor, when in the center of the English-speaking race, in the greatest city of Christendom, this summer evils as bad as any in Chinatown have been unveiled, not among the debased and wretched, but among the highest, most cultured, most influential class of the community? Why chide the Mongol with his unwillingness to become a citizen, when we treat him in a manner more consonant with the narrowest policy of the dark ages than with the enlightenment of the nineteenth century.

What is the use of pretending respect any longer for our religion, if it acknowledges itself

unable to cope, even on its own ground and with every possible human aid at its command, with the Joss worship and superstitions of Chinese immigrants? If Christian professors take any such position, abolish their dogmas, and throw away the Bible as a piece of worn-out rubbish, for it has confessed itself vanquished on a field where everything was in its own favor.

But we cannot believe that the time has come for this. Let us, therefore, each and all of us, do what may be in our power to repeal the absurd and inconsistent laws which impede Chinese immigration; let us welcome such to our shores, and have faith that Christianity and free institutions are still strong enough to strive with the outgrowths of tyranny and idolatry, and will add another glorious victory to the many recorded in the past.

A TYPICAL CASE OF CHOLERA.

Whether through the desire to gain notoriety as being the first to report a case of cholera in a given locality; whether to gain reputation for the ability to cure cholera, or whether through inability to make a differential diagnosis between Asiatic cholera and the diseases that resemble it, we do not know; but it is a fact that ever and anon the community is startled by the report from Dr. So-and-So that he has had a case of cholera. Upon examination it proves to be cholera morbus or some equally simple trouble. Just now when cholera is raging in Europe, these false rumors are not uncommon in our country. That our readers may know how to diagnose the disease when it really does come, we will report the history of the case of Asiatic cholera that occurred in the Lambeth Infirmary (England) on July 29, 1884.

A man aged 35, a porter and an inmate of the Lambeth Workhouse, was seized with violent vomiting and purging, accompanied by cramps in the abdomen and legs. He was removed to the infirmary, and on admission was found to be in a state of collapse; surface cold and clammy; skin over chest and legs blue; voice (naturally strong) brought to a whisper; pulse almost imperceptible and very rapid; face pinched; skin over hands and fingers in wrinkles, and blue; complains of cramps in abdomen and legs; intense thirst; feels sick; tongue and breath cold. Turpentine stupes to abdomen were ordered, hot-water bottles, hot blankets, hot peppermint; ice to suck. 5 p. m.: Was purged about three times within the first hour after admission, and in the afternoon vomited a chamberful of dark fluid; has passed no urine; temperature 97°. Stimulating aromatic mixture ordered.

July 30th. 10 a. m.: Vomited three times since last report; no purging; no urine; temperature 97.4°. 6 p. m.: Vomited several times during the day; purged frequently; offensive stools, with light-colored fæces; great thirst; restless; temperature 97°.

31st. 10 a. m.: Passed a quiet night; no vomiting; no purging; no urine; temperature 96°, but appears warmer; thirst not so intense. 6 p. m.: Voice very low; delirious; no vomiting, purging, or urine; temperature 97°; profuse sweating.

Aug. 1st. 5 a. m.: No purging, vomiting, or urine; temperature 97°. 8:30 a. m.: Temperature 98°; thirst not so intense. 4 p. m.: Sudden change and death took place about 6 p. m.

That this was a case of true Asiatic cholera was attested to by no less an authority than Sir James Fayrer.

Of course, we may have all grades of the disease; while this man lived nearly four days after the onslaught, some will die in a couple of hours; but we can accept this case, coming from so high an authority, as a type of the disease to aid us in our differential diagnoses.

POLICE SURGEONS.

When our present Mayor entered office, he endeavored to inaugurate a corps of Police Surgeons, and went so far as to appoint the chief of the corps, who still holds the office. But Councils would not heed his request, and failed to pass the ordinance providing for the appointment of such a corps. Philadelphia is notoriously conservative, and conservatism, not carried too far, is

most commendable, but when carried to the extent that it often is in our goodly Quaker City, it savors of the ridiculous. We want and ought to have a well-paid corps of Police Surgeons, who should be liable to be called upon to attend prisoners and policemen who may be taken sick in time of duty. Army and Navy officers (who receive remuneration) are provided with gratuitous medical advice, and why should not our policemen be equally favored?

Again, and a very important *again*, is the point to be considered that every now and then we read of some poor unfortunate, who is taken to a station-house supposed to be drunk, and allowed to lie upon and toss about the hard wooden floor of a cell, when in reality he is dying from acetonæmia, uræmia, apoplexy, or some coma-producing disease. Such a man requires skilled medical treatment, and the voice of humanity calls out in clarion tones that he shall receive it; his life is in the balance, and a skilled hand is required to turn the scale in his favor. The lectures that have been given to the police on "first aid to the wounded" are very good so far as they go, but they go not far enough; they educate the police into their duties in the emergencies of accidents, strictly so called, but it requires the trained eye and experienced mind of the physician (and a good one at that) to detect the true nature of a comatose condition. If one or two of our influential Councilmen were to fall on the street with uræmic coma, and being arrested for drunkenness, be allowed to batter about a cell for a day or so, we might hope for a well-paid corps of police surgeons.

THE INTERNATIONAL CONGRESS CONTROVERSY.

"These be bitter words, Captain."—*Mrs. Quickly.*

In a long observation of medical controversies, we think we have never read more bitter and personal diatribes than have appeared with reference to the projected International Congress in this country. No matter what the provocation, there can be no excuse for such scandalous abuse.

The case appears to us to lie in a nutshell.

In 1884, the American Medical Association appointed a committee of seven members to make arrangements for the International meeting in this country. This committee went to work with energy, and in accordance with the veiws entertained by its majority, as to the most fitting scheme for the Congress and its sections. To aid in the work, it appointed a number of sub-committes in different parts of the United States. When the meeting of the Association was held in New Orleans this year, the committee, as in duty bound, handed up a report of its action. This report was submitted, but did not meet the approval of the majority of the Association, and, therefore, the committee *was increased*, and new members appointed to complete the work.

This is the simple and, it seems to us, very insufficient cause for all the bad blood which has been stirred up. The old committee at first claimed that the Association had no power to alter it. But competent counsel, to whom the question was referred, decided that the Association had this right. It may have been, and we think it was, a hardship, and, in a certain sense, an unfair act, to the first committee to modify it, as its members were certainly led to suppose that they held plenary powers, and that the approval of the Association would be a matter of form only. But on the other hand, the Association had a perfect legal right to act as it did, and its action should have been accepted by the old committee without bitterness.

Of course, there is an inside history to this row, but it is no easy matter to get at the truth of it. On the surface, it is a quarrel between new and old code factions. The committee first appointed are accused of favoring the new code and of intending to pave the way for irregulars to be present at the International Asssociation meeting. Of some of them this is credible, but certainly not of all.

The unseemly personalities which have been indulged in by both sides are especially to be regretted as the literature of the quarrel will be sure to come to the notice of foreign editors and medical readers.

Notes and Comments.

On Feeding the Sick.

A most useful paper on this subject (well worthy of a lengthy abstract) was read before the recent meeting of the British Medical Association by Dr. William Roberts. After discussing the general question of dietetics in a masterly manner, but rather from an historical standpoint, the author gives us, among a mass of valuable matter, the following peculiarly valuable points which we cull:

"I have sometimes observed the existence of a low standard of health, without any very definite symptoms, which I could only attribute to a too protracted abstinence from fresh vegetables and fruit."

"The bad reputation of potatoes and pastry in regard to digestibility is chiefly due to the fact that they are often imperfectly cooked."

"The great majority of our patients are able to use ordinary diet. They consist of invalids who are suffering from various ailments of the slighter sort, or from some more serious disease, which does not interfere radically with the digestive functions. In regard to all these, I take it that (except in special cases, which I do not purpose to consider) it is a sound canon of practice to adhere to the main features of the current dietetic habits, and to avoid teasing our patients with irksome and needless restrictions for which we cannot give a clear reason."

"We must study the peculiarities and idiosyncrasies of the patient's stomach; which are as individual as their faces, and are very peremptory in regard to their likings and dislikings." Some observations on the effects of food accessories demonstrated that "The distilled spirits—brandy, whisky, and gin—were found to have but a trifling retarding effect on the digestive processes, whether salivary or peptic, in the proportions in which they are commonly used dietetically. Their obstructive effects only became apparent when used in quantities which approached intemperance."

"Wines and malt liquors were found to be highly inimical to salivary digestion, this was obviated when mixed with soda, seltzer or some effervescent table water."

"On *peptic* digestion wines have a retarding effect out of proportion to the alcohol contained in them."

"Champagne was found to have a distinctly less retarding power than an equal volume of claret or hock. This I judged to be solely due to the mechanical effects of the effervescence and liberation of gas, whereby a more efficient stirring up of the digesting mass would be effectuated."

"Tea has an intense inhibitory effect on salivary digestion, due to the tannin in the tea leaf, and which it is impossible to eliminate in the manufacture of the beverage, since tannin is as soluble as sugar in hot water; this in effect however may be overcome by eating first and drinking the tea afterwards."

"Coffee and cocoa have only a slight effect on salivary digestion. The effects of tea, coffee, and cocoa on *peptic* digestion were found to be as nearly as possible alike for infusions of equal strength. All three exercised a retarding effect when their proportion in the digesting mixture rose above twenty per cent. These beverages should therefore be taken very moderately by persons of weak digestion. The good reputation of cocoa in regard to digestion seems to be wholly due to the fact that it is used in weaker infusions than tea and coffee. The directions for the preparation of this beverage, printed on the packets of cocoa sold in the shops, indicate a strength of about two per cent.—whereas a medium tea is usually made of a strength of four to five per cent., and a medium coffee of a strength of five to seven per cent. The strong coffee which it is customary to hand round after dinner must have a powerful retarding effect on gastric digestion, and although this practice may be salutary to robust eaters, it is not to be recommended to those of feeble peptic power."

The Diagnosis and Treatment of Tumors of the Bladder.

Such is the title of a paper read before the recent meeting of the British Medical Association by Mr. Reginald Harrison, and, as usual with all that he says, it is brimful of practicality. In order that we may arrive at a correct diagnosis, it is oftentimes necessary that we make a digital examination of the bladder, and in order that we may do so Mr. Harrison unhesitatingly gives the preference to the operation of perineal urethrotomy. Even should the examination then demonstrate the tumor to be of such a nature or in such a location that its removal could be best effected by a supra-pubic operation, there is nothing to prevent the addition of this incision, but the great advantage in thorough drainage from the perineal incision cannot be overestimated. The viscus is occasionally sacculated, the ureters are patent and frequently largely distended, whilst the kidneys are rarely sound where the obstruction caused by the growths has been of long continuance. Hence we have much to fear from any extension of a

suppurative process after the operation, as he has seen in two instances which have recently come under his notice. One of the best safeguards against a contingency such as this, is thorough drainage, and this he thinks can best be secured through an opening in the perineum.

When, after the bladder had been opened and explored, it seems practicable to remove the tumor, this should be effected as completely as possible; to take away a portion of it is to leave the remainder to inflame, suppurate, and possibly to become gangrenous, thus providing a fruitful cause for pyelitis, through the largely dilated ureters. If, however, the connections of the tumor are extensive, and there is a doubt as to whether all can be got away without doing serious damage to the bladder itself, he feels sure that we had better content ourselves with the opening, which may under all circumstances be safely made, and the drainage that this opening with a suitable apparatus will provide. The lesser proceeding has in many instances proved the means of arresting hemorrhage, and of adding materially to the comfort, as well as to the life of the patient, even where it has been found impossible either to remove the tumor, or with safety to reduce its size.

In the case of an epithelioma of the bladder, to attempt its extirpation is obviously out of the question; to explore it with the finger, and to feel so far satisfied, and at the same time to give the patient an opportunity of emptying his bladder completely by means of a short and open road so long as he lives, is legitimate; nay, further, experience has already sufficiently shown that there is no better way of controlling the considerable bleeding which nearly always attends these cases, than by providing the means of permanently maintaining the bladder in a condition of more or less contraction.

Diet for the Sick.

In speaking of milk as a diet for the sick, Dr. William Roberts (before the *Brit. Med. Ass.*) says that not infrequently the stomach is not able to digest the milk and we have curds passing from the bowels; here he recommends peptonizing the milk by means of pancreatic extracts. The bitter flavor of peptonized milk is, however, nauseous to many invalids, and you cannot fully peptonize milk without developing this unpleasant flavor. One of the best means of covering the taste of peptonized milk is to add coffee to it. Another device, which may sometimes be adopted with advantage, is to add the pancreatic extract to cold or iced milk. In the cold the action of the ferment is comparatively slow, and it takes some hours to produce an appreciable change of flavor. But as soon as milk, thus charged with the ferment, is swallowed and passes into the warm atmosphere of the stomach, it is rapidly digested.

A new preparation consisting of the pancreatic enzymes in a highly purified state under the form of a light, nearly white powder, is absolutely free from taste and smell. Combating again the popular and erroneous idea of the nutritive value of beef tea, Dr. Roberts says: "Beef tea and its congeners, however, take rank as restoratives and stimulants rather than as nutrients. They contain no albuminous matter in solution, and the small quantity of gelatin contained in them cannot be of much account. There is a widespread misapprehension among the public in regard to the nutritive value of beef-tea. The notion prevails that the nourishing qualities of the meat pass into the decoction, and that the dry, hard remnant of meat-fibre which remains undissolved is exhausted of its nutritive properties; and this latter is often given to the cat or dog, or even, as I have known, thrown away as useless rubbish into the midden. A deplorable amount of waste arises from the prevalence of this erroneous notion in the households of many who can ill afford it. The proteid matter of meat is, as you know, quite insoluble in boiling water, or in water heated above 160° F. The ingredients that pass into solution are the sapid extractives and salines of the meat, and nothing more, except some trifling amount of gelatin. The meat remnant, on the other hand, contains the real nutriment of the meat—and if this be beaten to a paste with a spoon, or pounded in a mortar, and duly flavored with salt and other condiments, it constitutes not only a highly nourishing and agreeable, but also an exceedingly digestible form of food.*

Speaking of cold made meat infusions, he says: "Infusions made from minced meat with half its weight of water, and allowed to stand for two hours, and then pressed through cloth, were found on analysis to contain over four per cent. of dry albumen. This amount of proteid is equivalent to that contained in cow's milk. The nutritive value of such infusions is, therefore, very high. When heated to the boiling-point they coagulate into a solid jelly. Made from beef or mutton, the product has an unpleasant bloody appearance;

* These remarks on beef-tea apply equally to Liebig's Extract of Meat, Brand's Essence of Beef, and Valentine's Meat Juice—all of which are devoid of albuminous constituents.

but when made from veal, the coloration is much paler. The best preparation, however, is made from the meat off the breast of a chicken."

While cooked eggs are more digestible than raw ones, yet when the stomach is weak and unable to digest solid food, beaten-up eggs pass through the duodenum without being meddled with, and are slowly digested in their passage down the intestine.

Anæsthesia Through Cauterization.

Dr. Jules Guerin (*Gaz. des Hopiteaux*, 47,) says that chloroform narcosis, in spite of all caution, carries with it a certain amount of danger. On this account the author has endeavored to find an anæsthetic which does not, as chloroform and similar anæsthetics, act on the whole system, but only anæsthetize that part alone which is to be operated upon. He reported the following case;

A lady, æt. 60 years, who had a swelling in the right breast for 7 to 8 years, was sent to Guerin for an operation. Examination showed the presence of an undoubted carcinoma of the right mammary gland, which was grown to the skin, but which on the under part was still freely movable. No carcinomatous glands were to be felt in the axillary region. The general condition of the patient was lowered by a long continued bronchitis, with strong cough and expectoration. Besides this, the heart's action was very irregular. To exclude his patient from the danger attendant upon chloroform, the author did as follows: At a distance of four-fifths of an inch from the carcinoma he applied a layer of Vienna paste; after fifteen minutes the pain had completely discontinued. Five minutes later the paste was removed, and a dark ring was seen where it laid, encircling the tumor. By means of a fine platinum wire which Guerin had drawn through under the tumor by means of the sound, it was drawn outward. The doctor then cut the soft parts through in the line of the cauterization, without blood or pain. Then the whole base of the mammary gland was removed by means of fingers and scissors. The whole operation continued only ten minutes, and the patient lost scarcely two to three spoonfuls of blood. It was necessary to ligate but one artery.

The repair took place in a favorable manner, and the bronchitis improved. The scab from the cauterization, which fell off after three weeks, formed a protection against the absorption of septic material.

To what extent this "caustic anæsthesia" will supplant chloroform in severe cases, must be left, as the author said, till we have had more experience.

The Treatment of Cholera.

Though we are probably spared from this frightful disease (that has killed some 75,000 persons in Spain this summer and paralyzed business) yet it is rather more than likely that we will have it next summer unless our sanitary authorities are extremely vigilant. Hence it is well to gather together all that is reliable in reference to treatment. Dr. John H. Trader, of Sedalia, Mo., tells us through the *St. Louis Courier of Med*, July, that some ten years ago they had in their neighborhood a few cases of what appeared to be genuine Asiatic cholera, (though most likely it was not, as it was limited to a few cases,) yet it was so pronounced by Dr. T. J. Montgomery, who had passed through several epidemics of the genuine disease. Dr. T. had made up his mind that the best way to treat the disease was by hypodermic medication, so he provided a mixture of chloroform and glycerine and one of carbolic acid and glycerine. To the first patient to whom he was called he gave by a mistake the carbolic acid; the patient told him he had killed her, went off into a sound sleep, awoke after five or six hours much better, and next day was well. Since then Dr. T. has extensively used the following:

℞. Glycerole of carbolic acid,
Glycerole of chloroform,
Tinct. opii,
Tinct. matico,
Camphor water,
Aqua menth. pip.,
Aqua menth. virid., ℥j. M.

Of this mixture he gives about 15 to 20 drops every five to ten minutes in hot water until relief is obtained. He says that he was not, and is not now, disappointed in the power of this combination. He rarely ever fails to arrest disturbance of the stomach or vomiting depending upon disordered stomach, especially where the element of fermentation is present.

A New Method of Testing for Albumen.

Mr. G. P. Best describes in the *Brit. Med. Jour.*, June, 1885, an ingenious plan for testing urine. He dips a glass syringe into the chamber-utensil and draws up a small quantity of the urine, and then, inserting the nozzle of the syringe into nitric acid, sucks in a drop or two of that fluid; the well known hazy line at the touching point of these two fluids indicates the presence of albumen.

CORRESPONDENCE.

Why the Dram-Drinker's Nose is Red.

EDS. MED. AND SURG. REPORTER:—

It may be reasonably supposed that when the dram-drinker looks upon his face in the mirror, and sees that his nose is red, he would be anxious to know the exact cause of such a condition, and why the more alcohol he drinks, the greater becomes the redness; and also, why angry looking bumps, after awhile, make their appearance on the end and sides of the nose? It may not be out of place to tell him, in a commonplace way, the cause; for he is but little aware, as he looks at his nose, that, as it is reddened and congested by an unnatural supply of blood, so all the respective organs of his body are kept in a state of unnatural redness and congestion by the habitual use of alcohol. If he could see his brain, stomach, liver, lungs, heart and kidneys, in his mirror, as he sees his nose, he would find each of those organs in precisely the same condition as that presented by his nose; and this congestion of the vital organs explains to him the uncomfortable manner in which their functions are performed.

THE SYMPTOMS.

When in perfect health, the functions of the organs of the body are so quietly performed, that a man forgets he has lungs and heart. In fact, his general condition is so good, that he never thinks about his internal organs; but this is not so with the habitual drinker of alcoholic compounds. The alcohol which he drinks, keeps his organs in the same reddened and congested condition as his nose, and he is always complaining that his head aches, or feels hot, foolish and confused, that he does not sleep well, and has startings and jerkings of his limbs in his sleep; his appetite is capricious, his kidneys do not act well, and he has pains in his limbs and back, or his heart feels uneasy and has spells of palpitation, and his lungs do not perform their duty in a manner to make him feel at ease. He is nervous, tremulous, and easily startled; his liver is disordered, he has a bad taste in his mouth, and his tongue is coated with a thick white fur, accompanied by feverish and thirsty sensations about his throat. When the dram-drinker presents or complains of these symptoms, he may, without the slightest mistake, conclude that the alcohol has irritated his whole system, and that every organ of his body is in the same reddened and unnatural condition as that presented by his nose.

THE EXPLANATION.

The heart is a double organ, constituting within the body a force-pump, the duty of which is to receive two streams of blood, and to act upon them in a manner which necessitates the duty of sending two streams of blood in different directions. It has, likewise, two sets of vessels. The duty of one set of vessels is to carry the blood *from* the heart throughout the entire body, while the duty of the other set of vessels is to carry the blood back from the entire body *to* the heart to be sent to the lungs to meet with the air, by which it is purified. This explains how it is that the dram-drinker's breath always smells of alcohol. The alcohol when taken into the stomach passes in a pure state into the blood; and when the blood, thus mixed with alcohol, is sent by the action of the heart to the lungs, the alcohol is there taken up by the air in the lungs, and breathed out on the air by the act of breathing. Sometimes the breath is so loaded with alcohol, that the breath, as it escapes, will appear luminous, and can be plainly seen to be luminous when the long-practiced dram drinker breathes in the dark.

HOW THE ORGANS ARE DISEASED.

The vessels which carry the blood *from* the heart throughout the body, are called *arteries*. Those that bring it *back* to the heart, are called *veins*. The veins collect the blood from the organs and remote parts of the body, as rapidly as the arteries send the blood to such organs and remote parts of the body. If the heart therefore sends the blood to the different organs and parts of the body more rapidly than the veins can collect it, then more work is put upon the veins than they can perform, and the result is, a stagnation or congestion of the amount of blood sent in excess by the arteries for the veins to gather. Hence, as the dram-drinker's heart beats about thirteen times oftener in the minute than the heart of one who does not drink alcohol, the arteries in consequence of the increased action of the heart carry the blood to the dram-drinker's nose more rapidly than the veins carry it back, and the blood remains congested in the over-filled vessels, and gives the nose, face and neck of the dram-drinker an habitual redness. So stagnant is the blood thus congested in the over-filled vessels, that when the nose, face and neck of the dram-drinker suddenly meet a current of cold air, they immediately turn purple, and retain the hue until the warm air again restores them to their unhealthy redness. The blood thus stagnant in the dram-drinker's nose, not only causes its redness, but produces disease of the skin, and this disease of the skin causes red pimples to sprout out. In medicine, these pimples are known as *acne*, but in common language they are called *grog blossoms*, and these grog-blossoms never get well so long as the continuous use of alcoholic compounds is kept up.

THE INEVITABLE RESULT.

It is a medical fact, that as the influence of alcohol reddens the dram drinker's nose, and changes its appearance, so the alcohol reddens and changes the appearance of every organ of the body; and as the nose thus affected is not either in a natural or healthy condition, so every organ of his body, like his nose, is changed from a natural and healthy condition to an unnatural and diseased condition; and as the skin of the nose takes on unhealthy action, so the substance and covering of the internal organs take on diseased action, which results in a short time in the full development of incurable diseases, such as insanity of the brain, diseases of the heart, Bright's disease of the kidneys, hob-nail liver, and slow inflammation of the stomach. All these diseases exist at the same time in the dram-drinker; but the organ most diseased is apt to take the lead in the process of morbid action; and the other organs

being also in a state of advanced disease, the law of destruction soon asserts its power, and the dram-drinker passes anon from untimely disease into a premature grave.

News and Miscellany.

MEDICO-LEGAL NOTES.

BY HENRY A. RILEY, ESQ., OF NEW YORK.

A Farm for Lunatics.

The Legislature of New York some two years since authorized the purchase of a farm where the harmless lunatics now confined in the public institutions of New York City could be employed in light occupations. The Commissioners of Charities and Correction for a year and a half have been attempting to put this humane law into effect, and have made four different selections of tracts of land. In each case, however, the counsel to the corporation found some flaws in the titles, and advised that the purchase be not completed. The last selection made has a good title, so Mr. Lacombe reports, and the matter will at once be closed. The farm consists of about 900 acres, and is situated on Long Island, forty-three miles from New York. The tract consists of wild land, unimproved, but well watered and timbered. Next year the work of clearing the land and erecting buildings will be begun. The Commissioners of Charities and Correction have under their control more than five hundred harmless lunatics, who will all be benefited to some extent by light outdoor employment. The male lunatics will be employed as woodchoppers, ploughmen, and general farm hands, while the women will manage the dairy and poultry yards. Vegetables, butter, eggs and milk will be produced, it is expected at lower prices than are now paid for such supplies at the public institutions.

A Contract for Services in Settling with a Railroad Company.

The Michigan Supreme Court has just decided that it is contrary to sound public policy for a physician to agree with a patient injured in a railroad accident to accompany him to the officers of the railroad, explain the injury and its probable effects, receiving for compensation a sum graded according to the amount paid by the railroad company. The ground of the decision was that the physician was accepted by the railroad company as an impartial man, and they were to abide by his decision, and this being the case, a secret agreement which would give to the physician a higher compensation if he secured a larger sum from the company was so likely to render him biased that the agreement could not be held valid.

The court says that "such secret agreements by persons putting themselves in positions of confidence, come within recognized prohibitory rules as tending to defraud."

Injunctions Against the Adulteration of Food.

The remedy against adulteration of food products in New York lies more in an ordinary suit for damages than in the issuing of an injunction against the sale of the harmful articles. The latter is the easier and the quicker method, and is frequently applied for; but the courts generally refuse to grant it unless it appears that an injunction is necessary to "prevent irreparable mischief and also to suppress offensive and vexatious litigation." The rule is stated to be in one case as follows: "It is not every violation of the rights of another which may be ranked under the general head of nuisance which will authorize the interposition of this court by means of an injunction. It must be a case of strong and imperious necessity, or the right must have been previously established at law, or it must have been long enjoyed without interruption." There seems to be no certain criterion to go by, but the courts in each instance that comes before them, will judge whether the danger from the adulterated articles requires the summary process of injunction.

The Michigan Law for Ante-Mortem Probate of Wills.

The Michigan Supreme Court has recently declared that a statute which provides for the probate of a person's will before his death is inoperative and void. This statute attracted considerable attention at the time of its passage, as it was expected that it would have a tendency to prevent vexatious and expensive will contests, and similar bills were presented to the Legislatures of other States, but we believe were not passed. The effect of the law in Michigan has been, it is said, to be what was hoped for, but nevertheless the Courts have declared it unconstitutional and void by reasoning which it is hard to meet. The main ground of the decision is that the law permits relatives to appear and contest an *ante-mortem* will, who could have no rights at all until after the testator's death, and also puts them in a position of antagonism to him when they are supposed merely to represent him. It is also said with much force that the machinery of the law is set in motion to establish a will which the testator can an hour after destroy by executing another will, or which would be wholly inoperative by the death of the beneficiaries. The Court considers that the probate of a will before death does not come within the recognized judicial power of any tribunal, and that the law allowing it must be void. No will can be probated except as a help to administer the estate, and there is no estate until the testator dies.

Microbes in Sewage Irrigation.

The *Popular Science News*, August, 1885, refers to a curious experiment, shown a year or two ago, in which a long glass tube was filled with earth, and sewage poured in at the upper end. If the tube was long enough, perhaps six or eight feet, the liquid issued from the bottom clear and pure; its dissolved and suspended organic matters having been oxidized by the soil. If, however, before pouring in the sewage, a little dilute chloroform was allowed to filter through the earth, sewage subsequently applied passed through the tube without change; the oxidizing action of the soil being completely suspended. After some hours

or days, the soil regained its oxidizing quality. This experiment was believed to show that the oxidation of organic matters in sewage was something more than a chemical reaction, and that it depended, at least to a certain extent, on the presence of small living organisms, whose activity could be temporarily suspended by an anæsthetic, and with it the oxidation of the sewage. This theory has now been confirmed by additional observations; and the little creature which converts into fixed and harmless salts the putrefying impurities of such sewage as it can reach, is believed to be a micrococcus somewhat resembling the yeast-plant. Many and varied tests have been made to determine the conditions under which the disinfecting microbe lives and acts, and a good deal has been learned about its habits. It is found that it flourishes best, and is most efficient, at a temperature of about 98° F., nearly the temperature of the blood. At higher or lower temperatures its action becomes more feeble, and ceases altogether near the freezing point, or above one hundred and thirty degrees. Experiments to show its distribution in a clay soil prove that it is most abundant in the upper six inches, but is found to a depth of a foot and a half. Below that depth it cannot live, and soil taken more than eighteen inches below the surface has hitherto always failed to induce any change in nitrogenous solutions to which it was applied. These experiments cast a great deal of light upon many questions of sewage disposal by subsoil or surface irrigation; and further tests, made with some reference to this, would be easily made and extremely valuable. It is found, for instance, that nitrogenous solutions, in order to be acted upon by the oxidizing ferment, must be alkaline; acid liquids remaining unaffected. This observation shows at once that, where sewage is to be purified by irrigation, chemical wastes must be kept out of the drains. Normal house sewage is generally slightly alkaline, and in good condition for conversion; but the admission of the acid or poisonous wastes from a dye house, metal-working shop, or manufactory of any other kind, might render the sewage of a whole town incapable of purification.

Women Doctors in India.

Professor Rachel Bodley, Dean of the Woman's Medical College of Pennsylvania, has received a letter from Dr. Anna J. Noburn, a graduate of the class of 1882, who is now in India, asking her to send "medical women" to that country.

Dr. Noburn, writing from Simla, India, says that the women can act as missionaries and work for a specified salary, and adds:

"I went yesterday, at the request of Lady Dufferin, the wife of our new Viceroy, to talk over plans for establishing dispensaries and training schools for native women all over India.

"The idea was suggested to her first by the Queen, before she left England, and now she is making an effort to carry the idea out. Her plan is to raise a fund in India, from whatever sources she can, and from this support the work.

"I am not able to say what salary could be guaranteed, but it would probably be equal, all things considered, to what an ordinary doctor would make at home, and then it would be an assured income, which, of course, is an advantage. Lady Dufferin says that she herself would prefer those who would come as missionaries, but that some object. I told her, what persons of more experience than myself say is true, that the natives will choose the missionary physicians in preference to the others.

"A new hospital has just been opened in this place (Simla), and the surgeon in charge is anxious to get a lady doctor to take charge of the woman's ward, and one who can train classes of native women for midwives. He is willing to give $80 per month and a house, and as living in India is cheaper than at home, this sum is equal to a little more than $1,000 per year.

"What can the Women's Medical College of Pennsylvania do for India? There will be little trouble, I think, in raising the money needed, for the natives of India are anxious to have their women treated by women. If people at home had a better idea of what India is like, I am sure they would be much more willing to come. I must say that I prefer this land, in many respects, to my own native Ohio, and believe that the work of a doctor is on the whole easier here than there, for those suited to this climate, as I seem to be.

"In this connection I would say, that only those graduates who are especially well fitted to be doctors should be sent to India, as the English doctors here scrutinize them most closely. To begin with, they think our system of medical education superficial—that we turn out doctors too rapidly. Whenever I have an opportunity, I make as good a defense as possible, but, at the same time, I do not think Americans are in too much of a hurry. I believe, however, that our doctors, as a class, do their work more conscientiously than the majority of those one finds in India."

Electricity and Hygiene.

The Paris correspondent of an English exchange tell us that M. Gariel, in a lecture given at the Normandy Société d'Hygiéne, has treated the question of electricity and hygiene. The connection between these two subjects is rarely realized. It is generally known that electro-plating replaces gilding and silvering with mercury; but, beyond this, little is known of the hygienic importance of electricity. The first example cited by M. Gariel is the electric sifting machine, better known in America than in England. The jerking movements formerly given to the sifter, in order to separate the flour from the bran, diffused among the surrounding atmosphere fine dust, inimical to health; it caused disturbance of the respiratory organs. Electricity is also of inestimable value as a life-saver in mines. Formerly, numbers of miners lost their lives because, when their fuse burned too quickly, they had not time to seek safety before it exploded; or, if it burned too slowly, believing it had gone out, and approaching to place another fuse, they lost their lives. Electricity induces explosion at the moment desired; if it fail, the locality can be approached without danger. Part of M. Gariel's lecture treated of the application of electricity to alcohol. The alcohol extracted from the residue of beet-root after it has been used for making sugar, contains aldehydes,

which are both unpalatable and dangerous to health. MM. Maudin and Schneider have constructed an electric instrument, which adds a sufficient number of molecules of hydrogen to these alcohols, so that by distillation, all alcohols may be obtained free from such dangerous substances. M. Gariel also referred to the application of electrical currents for the prevention of deposits in boilers; and for warming the atmosphere, a method especially desirable for confined areas, such as railway-carriages. He also touched on the benefit to public health that would result from the use of the electric light. M. Gariel terminated his lecture by a few words concerning the influence of electricity on living beings. He believes that it must be extremely beneficial, but admits that its effects are all but unknown. Experiments on plants have given definite results, but are somewhat contradictory. M Gariel's lecture is published at length in the May number of the *Revue Scientifique.*

A Cow-boy's Bill of Fare.

One is accustomed to associate the idea of the out-door life led by cow-boys with the most robust health. That their strength and toughness is due more to their constant inhalation of pure air and their comparative freedom from the temptations of civilization than to the variety and delicacy of their food, the following menu will amply testify. When their day's ride is over, they gather a few sotol sticks and make a fire. Filling the coffee-pot with water from which the horses have drank and in which the cattle have waded, it is put on to boil. Cow-boys *must have hot bread three times daily;* so they cut off a few slices of bacon, put them in a skillet and fry them. The meat is then picked out, leaving the hot grease, to which they add a little water, put in flour, some baking soda, and a litle salt. This mess is stirred up till it becomes doughy. Then they take it out and play with it while a little with their hands. It is finally put back into the skillet, the cover put on, and fire is placed above, below, and around it. In a few moments the bread is baked or fried. Coffee, bacon, and bread; bacon, bread, and coffee; bread, bacon, and coffee, makes up the cow-boy's daily bill-of-fare, until he strikes some settlement, when fire-water is added to the list.

The American Rhinological Association.

We are requested to announce that the third anual meeting of the American Rhinological Association will be held at Lexington, Ky., October 6, 1885. Papers and discussion will be devoted exclusively to the diseases of the nasal passages and their sequences.

OFFICERS FOR 1885.

President—P. W. Logan, M. D., Knoxville, Tenn.

First Vice President—A. DeVilbiss, M. D., Toledo, Ohio.

Second Vice President—J. A. Stucky, M. D., Lexington, Ky.

Recording Secretary—C. A. Sims, M. D., St. Joseph, Mo.

Librarian—N. R. Gordon, M. D., Springfield, Ill.

Council—J. G. Carpenter, M. D., Stanford, Ky.; H. Jerard, M. D., East Lynne, Mo.; H. Christopher, M. D., St. Joseph, Mo.; E. F. Henderson, M. D., Los Angelos, Cal.

Information concerning the full programme, membership, papers, attendance, etc., may be learned from any one of the above officers of the Association.

Pennsylvania and Maryland Union Medical Association.

The Eighth Annual Reunion of the Pennsylvania and Maryland Union Medical Association was held August 27th, at York Furnace, on the Susquehanna river. Over a hundred physicians were present. They were from York, Dauphin, Chester, Lancaster and Delaware counties, Philadelphia, and Harford and Cecil counties, Maryland. Drs. Levis and Bair represented Philadelphia. The meeting was called to order by Dr. W. S. Roland, of York, President of the Society, who delivered the address. His subject was "The Social Relations of the Profession." The following officers for the ensuing year were elected: President, Dr. R. C. Broomell, Port Deposit, Md.; Vice Presidents, Drs. J. M. Deaver, Buck, Lancaster county, and G. S. Dare, Rising Sun, Md.; Secretary and Treasurer, Dr. S. J. Rouse, York; Executive Committee, Drs. Craig, Columbia; Houston, Collamer, Chester county; Virden, Lahadam, Md.; Milner, Delaware county; Bair, Philadelphia. It was decided to meet at this place again next year. After the meeting those present partook of dinner at Urey's Hotel.

The Veterinary Hospital of the University.

The hospital of the Veterinary Department at the University of Pennsylvania, in the new buildings at Thirty-sixth and Pine streets, was opened for the reception of sick and injured animals on Tuesday last. A circular letter from Dr. Huidekoper gives the rates for their board: For horses and mules the price is one dollar a day; for donkeys, cattle, sheep, and dogs, fifty cents a day; and for cats, birds, and small pet animals, twenty-five cents a day. Animals belonging to indigent and deserving persons will be treated without charge, and when taken into the hospital will pay board only. A blacksmith shop and competent farriers are attached to the hospital for shoeing lame horses, under the direction of the medical staff. The animals will be under the care of the veterinarians Dr. Huidekoper and Dr. Zuill.

Contributions are requested to the museum of the Veterinary Department, in the shape of diseased animals or monstrosities. The jaws, with teeth, of any animal—horse, cattle, sheep, dog, or hog—whose absolute age is known, and the entire heads of prize-winners and race-horses, will all be particularly acceptable.

Boston's Water Supply.

Since misery loves company, it is something of a gratification to Philadelphians who are compelled to drink Schuylkill water, to learn that Boston is in an equally sad plight. We learn that the publication recently of a report by medical experts who were appointed recently by the mayor to examine the sources of the city's water supply with reference to its purity, has caused a

great deal of excitement. This first report covers in detail only the Mystic system of supply, which furnishes water to about 150,000 persons, but it is intimated that disclosures equally bad will be made concerning the Cochituate system, which supplies the rest of the city.

It appears from the report which is made to the mayor that the banks of the ponds and streams of the Mystic system are lined with tanneries and other manufactories, the refuse from which is poured directly into the water, and that in some of the tributaries there is such an accumulation of filth that it can be taken up by the handful. The mayor has asked the new water board to act immediately, and it has promised so to do.

The Traction Conduits.

We have already noted that the Board of Health has declared the conduits of the Traction Company in this city a nuisance, prejudicial to health. The medical inspector of the Board has made an examination of these conduits, and reports as follows:

"The existing arrangements and constructions of the Traction Company, Market Street Line, was perhaps as good as any that can be devised, if properly attended to. It is necessary that the conduit should be kept clean in order that the cable may move freely. In order that the grip may take hold securely, it is necessary to pass the cable continually through a bath of tar and the residuum from the distillation of petroleum.

"By this means the conduit is kept deodorized, if not partially disinfected. To make the cleaning more thorough, the conduits should be flushed at least once a week."

Pierced by an Iron Rod.

Henry Sutton, a little more than two weeks ago, while engaged in agitating an oil well, attached an iron rod, known as the polish rod, to the sand pump line and lowered it to the bottom of the well. A sudden rush of gas threw the rod from the well and about thirty feet into the air, and in falling it struck Sutton on the right side of the neck, came out on the side below the breastbone, entered again at the hip, and emerged from the flesh at the knee. The vital organs were not penetrated, but it was thought there was very little hope of his recovery. In spite of this Sutton has continued to improve, and will most likely get well. The rod which passed through Sutton was three-quarters of an inch in diameter.

Injured by an Elephant.

One of the big elephants broke loose from his moorings in a circus tent in this city last Monday. Before he could be secured, he seized one of the employees with his trunk and viciously hurled him a long distance, injuring him severely. He was conveyed to the Pennsylvania Hospital—the man, not the elephant.

An Epidemic Among the Babies.

Advices from Mahanoy Plane, Pa., under date of August 29, state that almost every day new cases of cholera infantum are reported at Frackville. Several deaths have occurred. It is feared it will become an epidemic. Seven deaths have resulted from this cause the last two weeks.

A Druggist's Fatal Mistake.

Last Monday, in Hoboken, N. J., a physician ordered some powders, containing each ten grains of quinine, for two young ladies, to one of whom he was engaged to be married. By mistake the druggist put up morphia instead of quinine. One powder was taken by each of the girls, with fatal results.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended August 22, 1885.

Bailhache, P. H., surgeon. Granted thirty days leave of absence, August 15, 1885. Chairman of board to examine candidates for appointment as Cadet in the Revenue Marine Service, August 19, 1885.

Irwin, Fairfax, Passed Assistant Surgeon. Recorder of Board, August 19, 1885.

Compressed Tablets for Hypodermic Use.

The difficulty of adjusting with nicety the amount of active drug for hypodermic injection is neatly overcome by the employment of the "Soluble Compressed Hypodermic Tablets," advertised by Messrs. John Wyeth & Bro. They are prepared of a variety of ingredients, such as are most usually required in practice, and put up in small glass tubes. They simply require to be dissolved, and thus the physician can with no trouble have at hand a permanent form of exactly measured agents for his purpose.

A Rum-Crazed Man's Freak.

A well-to-do farmer, living near Weisburg, Dearborn county, Indiana, while in a condition bordering on delirium tremens recently, piled the bedding and furniture on the floor in his room, set fire to it, and then mounting a chair on a table in the middle of the room, and arming himself with a shotgun, bade defiance to his imaginary tormentors. When the neighbors rescued him his eyes were burned, and he was otherwise so badly burned that he cannot live. The house and its contents, worth $3,000, were destroyed.

Precautions Against Small-Pox.

We are pleased to learn that Drs. H. R. Mills, Myron Northing, John J. Mulheron, and Fitzhugh Edwards, have been selected for temporary duty at Port Huron and Detroit, Michigan, under directions from the Marine Hospital Bureau, to aid the State authorities in preventing the introduction and spread of contagious diseases from Canada. This action was taken by the Acting Secretary of the Treasury at the request of the Governor of Michigan.

The Rooks and Cholera.

The peasantry of South Germany have been thrown into a state of consternation over the sudden and inexplicable departure from the country

of the rooks which for centuries have made their abode there. The flock of rooks which nested in the spire of the Ratisbon (Bavaria) Cathedral, recently departed and have not returned. This general evacuation by the rooks is regarded by the people as heralding the approach of an epidemic of cholera.

OBITUARY NOTICES.

DR. FRANCIS ASHHURST.

Dr. Francis Ashhurst died August 17th, at his late residence, in Mount Holly, N. J., of congestion of the lungs. Dr. Ashhurst was a son of the late Lewis R. Ashhurst, and was born in this city, in January, 1842. He received the degree of Doctor of Medicine at the University of Pennsylvania, and was subsequently a resident physician at the Episcopal Hospital. Dr. Ashhurst was a member of the County Medical Society of this city, and other similar organizations. He removed about twelve years ago to Mount Holly, where he had a large and extensive practice. He was well known in Burlington county, where the family of his mother (formerly Miss Hazlehurst) have resided for over one hundred years. Dr. Ashhurst, in conjunction with his mother, founded the Burlington County Hospital at Mount Holly. It started from small beginnings, and there is now a commodious hospital building, occupied by a number of patients. It is the only hospital in the county. Dr. Samuel Ashhurst, of this city, and Mr. Richard L. Ashhurst, a member of the bar, are brothers of the deceased.

DR. D. H. GREGG.

Dr. D. H. Gregg, a wealthy citizen of King William County, Va., was found dead from apoplexy at a hotel in Richmond, on August 25th. He was in the 84th year of his age, and was a native of Boston, and a graduate of Harvard. He came to Virginia when quite young. An examination of his papers brought to light a will which made various bequests, amounting to about $50,000. A codicil leaves the residue of his estate, amounting to from $100,000 to $150,000, to St. Joseph's Female Orphan Catholic Institution of Richmond, the interest to be devoted to the education of female children, of Caucasian race, without regard to religion or nationality.

Items.

—In the *Boston M. and S. Jour.*, July 30, Dr. James R. Chadwick reports ten cases of pregnancy and labor, complicated with fibroids.

—The æsthetics of the sick room have received an impulse from Dr. Lawson Tait, who is said not to accept homely women as nurses for his patients.

—The Madras government, it is reported, is having cinchona extract made in large quantities for gratuitous distribution among the native population in fever-afflicted districts.

—Telegrams from Rome state that 200 persons have been poisoned through eating the ice-cream sold by an ambulant vendor of Riposti in Sicily, on the occasion of a local holiday.

—The false teeth of an elderly woman living near Logan, O., became dislodged during a severe spell of coughing, a day or two ago, and slipping into her throat, choked her to death.

—The Barotte prize of 3,400 francs, awarded to the inventor of the most important and useful invention for agriculture, has been awarded to M. Pasteur.

—Senator Allen, in the Baltimore *American*, writes that he was credibly informed when in the Gulf States, that a teaspoonful of powdered alum is a certain cure for rattlesnake bite.

—Thomas White and his wife Sarah, of Brooklyn, who are possessed of the idea that they are bewitched, have been committed to an asylum as lunatics. They are the persons who kept their dead child in the rooms until decomposition set in.

—It is stated that in the German army salicylic suet is now used universally for foot-sores, sores from riding, etc., and that is found much more satisfactory than the salicylic powder which was formerly used. The salicylic suet consists of two parts of pure salicylic acid, with ninety-eight parts of the best mutton suet.

—The other day a Sanford, Fla., physician, who suspected that some one was peeping through the keyhole of his office door, investigated with a syringeful of pepper sauce. He found his wife, half an hour afterward, with a bandage over her left optic, and she told him that she had been cutting wood and a chip had hit her in the eye.

—Sea-water can be rendered palatable by removing the chlorides, and Thomas Kay, President of the Stockport (Eng.) Natural History Society, says citrate of silver will do this. He says that one ounce of citrate of silver will convert half a pint of sea-water into a drinkable fluid, and a man can keep alive on it a day, or seven ounces will serve to sustain life for a week. He proposes that bottles of the citrate of silver should be secured in the life-boats of ships, and used when absolutely required.

MARRIAGES.

DOTY—BRUCE.—August 3d, 1885, in New York, at the residence of the bride's parents, Dr. Alvah Hunt Doty to Mary Thornton, daughter of Colonel Sanders D. Bruce, all of New York.

CALDWELL—MATTHEWS.—July 2d, 1885, at the residence of the bride's mother, by Rev. F. M. Hopkins, D. D., Dr. J. S. Caldwell and Miss Lillian Matthews, all of Cincinnati, O.

DEATHS.

ASHHURST.—August 17, 1885, at "Clover Hill," Mount Holly, N. J., Francis Ashhurst, M. D., aged forty-one years.

EVANS.—August 24, 1885, at Steelton, Pa., Dr. John F. Evans, of Downingtown, Pa.

FINLEY.—August 4th, 1885, at Fort Concho, Texas, Dr. Samuel Moore Finley, Acting Assistant Surgeon United States Army, oldest son of the late Surgeon-General Clement A. Finley, United States Army.

JUMP.—August 17, 1885, in the morning, at Dover, Del., Isaac Jump, M. D.

KING.—August 4th, 1885, in Washington, D. C., Dr. Hervey W. King, a well known clerk in the Navy Department for the past fifteen years.

MONTGOMERY.—August 3d, 1885, at Muncy, Pa., Hugh Montgomery, M. D., in the eighty-second year of his age.

DUODENO-CHOLECYSTOSTOMY—ERRONEOUS VIEWS OF IT CORRECTED.

BY J. M'F. GASTON, M. D.,

Of Atlanta, Georgia.

The study of biliary obstructions, and of the proper measures for their relief, has a peculiar interest at present, in view of the surgical proceedings which have been adopted and proposed by different members of the medical profession. Among these, I have suggested as a remedial operation in obstruction of the gall-duct an opening from the gall-bladder into the duodenum for the passage of the bile into the alimentary canal. This proposition has been illustrated by experiments on dogs and by demonstrations of its practicability on the human cadaver; but thus far has not been practiced on a living human being.

Amongst various notices of this operation indicating some misapprehension of my suggestion, I observe on page 100 of the *Medical Bulletin* for April, 1885, that Prof. Roberts Bartholow states, "The objection to the operation is, that the cystic duct is tortuous, and that the bile would have to make a long journey from the liver to the intestine, besides the uncertainty attending the operation itself."

While he understands perfectly, that it is taken for granted there exists complete impermeability of the duodenal orifice of the common duct as a condition for this proceeding, he seems to have overlooked the fact that a large portion of the bile finds its way ordinarily into the gall-bladder, and being there, it may be discharged directly through the cysto-duodenal communication into the alimentary canal; and hence it is begging the question to claim that this is a circuitous route for the bile.

If it is claimed that this process is objectionable when compared with that of an external fistulous opening in cases of obstruction of the gall-duct, his view, that the cystic duct is tortuous, holds as much against the cutaneous outlet as against the cysto-duodenal communication, and is not tenable in either case.

As I have stated that "should any communication with the duodenum exist, however small it may be, dilatation of the ductus choledochus should be attempted," the remarks of Bartholow touching the practicability of catheterization call for the special consideration of surgeons.

"There is great difficulty in exploring the cystic duct unless the sound is most flexible, for just beyond the gall-bladder the duct makes a sharp bend which it is difficult to pass. If the sound is very flexible and great care is used, it is possible to turn this bend and pass the sound into the cystic duct, but I think not beyond into the common duct." This difficulty was verified in my demonstration of the relation of the ducts in the dog, reported at page 83 of the *Southern Medical Record* for March, 1885, as follows: "Upon passing my probe through the opening from the sac into the cystic duct it descends readily into this, and passes into one of the hepatic ducts, but cannot be made to enter the ductus choledochus, probably owing to the angle at which they unite. I now introduce the probe from the opening of the common duct into the duodenum, and it is seen to

glide readily into the tube, but does not find its way into the cystic duct."

Yet, Dr. C. T. Parker reports that in his case he "passed a No. 10 Van Buren sound through the fistula and common duct into the duodenum," traversing, of course, the cystic duct in its course from the gall-bladder. And Dr. J. Marion Sims states in the autopsy of his case, that Mr. Ganal "was able to pass a probe from the gall-bladder through the ductus communis choledochus into the duodenum."

Hence, it seems that the anatomical relation of the ducts referred to by Bartholow, and indicated by me, does not preclude the passage of a sound or a probe; and these should admit of catheterization when not entirely occluded, which would seem to warrant my recommendation of attempting dilatation.

With the lights before us, it is clear that an effort should be made to overcome temporary obstructions of the common bile-duct before proceeding to attach the gall-bladder to the duodenum. I have only suggested a recourse to the cysto-duodenal communication when no outlet can be effected through the natural channel, and it should be distinctly understood that this process is advised only in cases with *permanent occlusion of the common duct.*

My paper was based upon the recognition of an impediment to the natural outlet of the bile from "obstruction of the gall-duct," implying necessarily the ductus communis choledochus. An occlusion of the cystic duct prevents its entrance into, as well as flow from, the gall-bladder, so that it did not come within the scope of my investigation, excepting as a complication of the remedial operation suggested, and hence I have presupposed its patulous condition in proposing an outlet for the bile by a cysto-duodenal opening.

In an article by Mr. Lawson Tait in the *British Medical Journal* of September 7, 1885, page 275, he summarizes the problematical difficulties which rise up before his mind in regard to making a communication between the gall-bladder and duodenum, and says that from his "experience of artificially-made fistulous openings, the chances would not be very great in favor of the artificial communication remaining long open." But when it is remembered how this fistulous opening is made by the destructive ulceration of the tissues constricted by the ligature, it will be understood that the constant flow of bile through this outlet should keep it patulous quite as well as the external discharge of bile preserves the cutaneous orifice open.

The preservation of an opening under such circumstances depends upon the persistence of the discharge, in like manner as the vaginal outlet from the bladder is kept open by the unremitting flow of urine in their fistulous communication. In the case of vesico-vaginal fistula there is perhaps no instance of spontaneous closure, and it may be expected that the bile escaping through this cysto-duodenal fistula shall prevent its closure.

It is true, that in my sixth case, when killed by the inhalations of sulphuric ether, after remaining over five months without any obstacle to the free discharge of the bile by the natural channel, the artificial opening made by the ligation had become obliterated; but this proves nothing as to the result in cases of obstruction of the gall-duct, when the discharge must be forced through the artificial opening continuously. Could the second operation, eight days after the first in this case, have enabled me to ligate the common duct, as was intended, and thus turned all the bile into the sac and thence through the fistulous communication into the duodenum, there can scarcely be a doubt but that the cysto-duodenal outlet would have continued open.

The superficial examination of my paper by Mr. Tait is indicated by his noting only the experiments on five dogs, when the sixth dog was the subject of observations upon which my chief claim for this operation is based.

An objection to my suggestion is urged upon theoretic grounds by Tait, that "the contraction might, in process of time, form a stricture of the duodenum." But practically no such constriction of this canal ensued in the case of my sixth dog, after more than five months had elapsed, and the specimen which I have preserved shows an entirely normal calibre, without any induration or stricture in its walls. So we may conclude that his apprehension is unfounded in fact. With the use of a single silk ligature to connect the walls of the gall-bladder and the duodenum, and effect a communication between their cavities, the requisite inflammation is induced for the adhesion of the serous surfaces, without material alteration in the textures of either the sac or the duodenal canal.

It is further alleged by Tait, that "it is perfectly certain that the proceedings which are recommended for dogs could not possibly be applied to the human being." This assertion is not based upon a knowledge of comparative anatomy, and is disproved by my demonstration on the human cadaver, of which a full report is given in the *Southern Medical Record* of March 20, 1885.

It will be observed that Tait assumes this position without having instituted a single experiment himself, and evidently without a proper understanding of those made and reported by me, so that his unsupported declarations cannot be accepted as in any way invalidating the evidence of facts which I have presented in favor of the efficiency of this operation, and the profession may rest assured that this proceeding will bear the test of experience.

A critique of my paper in the *Birmingham Medical Review* of March, 1885, takes issue with the operative procedure proposed by me, and from beginning to end manifests a total misconception of my views in regard to the gall-bladder and its dependencies. The author disregards entirely a fundamental point, that my article claims to discuss "obstruction of the gall-duct and its bad consequences," which so clearly implies the common bile duct, that no explanation is needed to comprehend that the cystic duct is not involved in biliary arrest or obstruction. While its occlusion may be attended with retention of bile, mucus, or sero-purulent fluid in the sac, this stoppage causes none of the peculiar troubles resulting from the obstruction of the outlet of the bile into the duodenum for which a remedial operation is suggested by me. Fortunately others are capable of understanding the facts, and comprehending my reasoning upon them, which will enable my readers to appreciate in its true light this flippant attempt at criticism.

There is one point referred to, indicating that the contents of the alimentary canal (and not fæcal matter as stated), may pass from the duodenum (and not from the intestine as alleged), into the gall-bladder.

Apart from the fact that no such complication is reported in the operation of Winiwarter, in which it is inferred that the cavity of the sac communicated with the intestinal canal, there was no evidence of such regurgitation in the dogs that lived from ten to fifteen days, with a free opening from the gall-bladder into the duodenum.

In the erect posture, and indeed under almost all attitudes of the body, gravity co-operates with the natural propulsion of the bile towards this dependent opening, and thus obviates any retrograde movement. While the gall-bladder ordinarily serves as a reservoir for the bile, which is discharged only occasionally, the creation of a cysto-duodenal communication allows the bile to flow out continuously, so that its cavity assumes the character of a canal rather than the nature of a receptacle, serving simply for the free passage of bile through it into the duodenum. Under such circumstances the walls of the sac become contracted, and the vis a tergo affords a steady pressure upon the fluid contents in a way to prevent the ingress of the more consistent alimentary mass in passing from the pyloric orifice of the stomach through the duodenal canal. The principle of the injection in hydraulics, bringing the force of the greater column to bear upon the lesser in their onward movement, should moreover afford some traction or suction, so as to favor the escape of bile into the canal. No apprehension of the possible regurgitation of the contents of the duodenum into the gall-bladder need therefore present a barrier to the adoption of this process in cases of obstruction of the common bile duct.

The editorial in Gaillard's journal setting forth the grounds for recognition of originality in conception and priority in execution on my part, in this cysto-duodenal operation, is not accepted by some, in view of the operation of Van Winiwarter to establish an entero-cholecystic fistula. Not only the *Birmingham Medical Review*, but the *Medical Record* and the *Medical News*, have shown a serious misapprehension, in supposing that this attachment of the gall-bladder to the large intestine first, and afterwards to the small intestine, as practiced by Winiwarter, corresponded to my operation by opening a communication by ligature between the gall-bladder and duodenum.

While I am far more interested in demonstrating the great practical importance of this proceeding, than in preferring any claim to consideration as its author, it may be stated that my conception of this surgical procedure was based upon "ulcerations connecting the gall-bladder and that part of the intestine adjacent to the duodenum" discovered in an autopsy made early in the year 1881, and upon my observation of a case on March 12th, 1881, that recovered from what was diagnosed as "obstruction of the gall duct with cysto-intestinal communication." The former is noted at page 366 and the latter at the top of 371, in the October number of Gaillard's Journal for 1884.

In the summer of 1884, when my experiments on dogs were undertaken, on independent preconceived principles, for demonstrating the practicability and utility of a cholecysto-duodenal outlet for the bile, I did not know of Winiwarter's case, though it was recorded in a foreign journal in 1882. Even when the details of these experiments were published in the September and October numbers of the *Atlanta Medical and Surgical Journal* for 1884, the notice of this operation by Musser and Keen, presented to the College of

Physicians and Surgeons of Philadelphia on September 3, 1884, and published in the October number of the *American Journal of Medical Sciences*, had not come to my knowledge.

But putting aside the question of priority, it is proper to note the difference in a pre-determined recourse to the ligature for opening a communication from the gall-bladder into the duodenum, which shall at the same time induce the firm union of their outer surfaces, from an incidental attachment of the sac to the large or small intestines, as done in Winiwarter's cases; and I appeal to the medical profession at large to decide this issue of originality and priority, which has been raised by the journals at home and abroad. As an offset to their misconceptions of my proposition, I respectfully submit the comments made upon my suggestion of a cholecysto-duodenal communication by the *Southern Medical Record*, the *Atlanta Medical and Surgical Journal*, and *Gaillard's Journal*, in an editorial subsequent to that accompanying my paper on "obstruction of the gall-duct, etc."

The first-named, in its number of January 20, 1885, says: "We observe that some of our exchanges take issue with the designation of this as 'Gaston's operation,' owing to the fact that Dr. Winiwarter had previously performed an operation for 'attaching the gall-bladder to the colon.'"

"If the physiological doctrine of the important rôle of the bile to the chylopoetic viscera be well founded (as we consider it is), there is a very wide difference in the result of carrying the bile into the duodenum and into the colon; so that there is really no ground for the claim of precedence in favor of Winiwarter's operation, as reported in the *Prager Medizinische Wochenschrift* in 1882, over Gaston's operation having a totally different aim.

"Dr. Gaston gives the result of some experiments upon dogs which are calculated to illustrate the practicability of uniting the walls of the gall-bladder and duodenum by an elastic ligature, and encircling this with stitches of catgut so as to effect adhesion of the surrounding surfaces when the opening is made by constriction and cutting of the tissues; and states that all the stages of these successful experiments have been verified at different times by fifteen of his colleagues in this city.

"A comparison of this process, for utilizing the bile by delivering it into its proper channel, with others, which remove it entirely from its appropriate spheres, either by directing it into the colon, or turning it outside of the abdominal wall, as in cholecystotomy, must be favorable to the adoption of the remedial operation suggested by Professor Gaston.

"The fact is clearly established by the experiments on dogs, that 'a fistulous opening through the adjoining walls results from the action of even a simple silk ligature attaching the sac to the intestine,' the bile being delivered where it belongs and of right ought to be, so that it only remains to test its practical application to man, for this operation to be recognized among the approved surgical procedures of this progressive age."

The *Atlanta Medical and Surgical Journal* of February, 1885, says: "The original experiments of Dr. Gaston were published in this journal, and we were present at the last operation of the series, in which the walls of the gall-bladder and duodenum were united by a single silk ligature. This was verified subsequently as successful in effecting the communications, and we are informed that the subject of it continues in a healthy condition at present, to undergo a final exploration shortly by a third laparotomy.

"Believing that this operation is destined to become an important curative agency in obstruction of the gall-duct, we deprecate the misconception of it by the *Medical Record*, of New York, for January 3, and by the *Medical News*, of Philadelphia, for January 10, in confounding it with the operation of Von Winiwarter for attaching the gall-bladder to the colon. As an operative procedure the latter has no more claim to precedence against the former than an attachment of the gall-bladder to the stomach, or to the urinary bladder, or even to the abdominal wall, might prefer over its union with the duodenum, which returns the bile to the natural receptacle in the alimentary canal.

"No measure thus far adopted in permanent occlusion of the gall-duct has proven satisfactory, and Gaston's operation offers the most favorable solution of the difficulty."

With this, I can bide my time for putting it into practice, and rest my claim to recognition upon the dying testimony of him who honored me by associating my humble name with this operation.

Gaillard's Medical Journal for January, 1885, states that "in Gaston's operation, the bile is introduced into the duodenum, and performs its important physiological functions; while in the operation cited by the *Record*, the bile is diverted from its physiological course, and is made to intermingle in the colon with the remains of the food, from which all nutrition possible has been extracted.

"Physiologically the operations bear no relation whatever to each other.

"Anatomically they are still more different.

"The *Record* tries to make the conditions after these operations similar by saying that Gaston has 'an exaggerated notion of the importance of the gall-bladder to the animal economy.' But Gaston in attaching due importance to the bile in digestion does not, on that account, include the gall-bladder in the estimate, but the bile producer, the liver.

"It is a very faulty and unreliable physiologist who undertakes at this day to depreciate the importance of the bile. Surely, if one is familiar with the teachings of Murchison, Bidder, and Schmidt, Frerichs, Harley, and others, he cannot commit such a blunder, or compare an operation in which the bile is allowed the force of its entire digestive role, with one in which it is discharged into the colon—that is, cut off from the food, and virtually discharged externally.

"It is true, that after the operation of cholecystotomy a number get well, and that both men and dogs live after a fashion, after they are deprived of the digestive and nutritive forces of the bile. But that does not touch the fact that food subjected to *all* of the gastric and intestinal fluids, the bile excepted, is not digested properly; whereas, as soon as the bile is allowed to supplement these incomplete forces, the digestion is normal and complete.

"Gaston's operation, therefore, is original. It is physiologically and anatomically an entirely different one from that cited by the *Record*, and it is, moreover, the only operation known for occlusion of the bile-duct, as a result of which digestion and nutrition are preserved normal and complete."

With such indorsement of this new process for conveying the bile into the alimentary canal, I feel warranted in commending it to the adoption of surgeons, and I shall feel no hesitation in availing myself of a suitable opportunity for testing its benefits on the human subject.

THE CHARACTER OF THE PULSE.

BY J. M. PINKSTON, M. D.,

Of Faunsdale, Alabama.

It is not that I intend presenting anything new, but merely to call attention to a fact of practical importance that may be of interest to some members of the profession that are not thoroughly conversant with the relation that the action of the heart bears to the radial pulse under certain circumstances. In the first place, in a natural pulse, or as long as the systole of the ventricle is sufficiently strong to force enough blood into the aorta to dilate the same, the aorta retaining its elastic force, by which the blood is driven onward, we may expect the pulse-rate to correspond with the systole of the ventricle; but when the heart's action is too weak for each contraction to force sufficient blood to dilate the aorta, it having lost a certain amount of its elastic force, we may not expect the pulse and contractions of the heart to be in proportion. It has been my sad experience to witness this disproportion in several cases in the last hours of life. Frequently when the pulse is so weak as to be felt only at intervals, we will notice it very suddenly get stronger and slower; now when this happens, it inspires the friends, and often the physician, with hopes; they regarding the change in the pulse as favorable, when in reality it may be one of the most unfavorable symptoms. Now in these cases, what we mistake for a pulse as indicating the action of the heart, in other words corresponding to the ventricular systole, is only a pulse-wave representing about one-third of the contraction of the heart and aorta. When the vital forces have given way to the extent as above stated, there being a very moderate quantity of blood pumped into the aorta by each ventricular systole, and the aorta being almost in a state of inertia, having lost to a certain extent its elasticity, though an extensible tube, would necessarily require two or three contractions before the stimulus would be sufficient to cause contraction of the aorta to force the blood onward; therefore there would be one or more secondary waves to follow and be fused into the primary before reaching the radial artery. I have seen this mistake made in more than one instance, for which reason I call attention to the fact, that we may always examine the heart of a dying patient, and not be deceived by a seemingly hopeful pulse dependent on very unfavorable circumstances, and be induced to inspire the friends with hopes at a time when the symptoms are the most unfavorable.

—An English editor has been struck with some of the answers in the school-children's examination-papers in popular science, and gives a few specimens of them. Among them are "the humerus (or upper arm-bone) is known as the 'humerus,' and is often called 'the funny-bone.'" "The sweet-bread is otherwise called the pancras (for pancreas), which is so named from the Midland Railway Station in London." "A thermometer is an instrument used to let out the heat when it is going to be cold."

HOSPITAL REPORTS.

LECTURES ON INSANITY.

Delivered at the University of Pennsylvania,

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by WILLIAM H. MORRISON, M. D.

LECTURE VI.

The Case of J. C., Hanged for Killing a Young Woman—Monomania Chiefly Showing Itself as Erotomania.

GENTLEMEN: To-day I shall give most of the hour to the discussion of the case of J. C., a man whom, with Dr. H. E. Goodman, I was called to examine as to his mental condition the day before his execution. The recollection of the examination will not soon fade from my mind; at present it remains so vividly with me that I trust I will be able to relate to you without effort its main features.

In my last lecture I began the consideration of the subject of monomania, discussing the various meanings which have correctly or incorrectly been assigned to the word; defining the term, as I purpose to use it until I find a better; and speaking of some of its divisions and subdivisions according to different authors—simple monomania, or monomania without delusions, and delusional monomania; intellectual, emotional, and volitional monomania; megalomania, etc.

The prominent abnormal mental characteristics of the man whose story I hope to tell to-day—so far, at least, as those characteristics could be determined by a single protracted interview—were enormous egotism and vanity, absence of anything like a moral sense, a lack of judgment and logical power amounting almost to imbecility, and silly, exaggerated, and delusive ideas with reference to women.

This latter characteristic constitutes a form of erotomania, which may be defined as one of the so-called monomanias, in which the patient develops a romantic affection, which may or may not be connected with sexual passion, for individuals of the opposite, or sometimes even of the same sex.

To help you to a better understanding of the subject, let me, before taking up our special case, say a few words about the victims of erotomania. Hammond* gives the details of several interesting cases of this kind. A young lady of good family developed a romantic affection for a gentleman whom she scarcely knew. She talked about the object of her admiration almost continually; she wrote fulsome sentimental letters to him; she followed him to a hotel and publicly declared her love and admiration. She finally was put under medical care and treatment. Erotomaniacs often single out public characters—actors or actresses, singers, statesmen, millionaires or millionaires' daughters, prominent clergymen, public officials, etc. Sometimes, as stated by Hammond, failure to secure recognition causes a change in the character of the emotion, and leads to violence or murder.

In 1816, an actress, Miss Frances Kelly, was shot at the Drury Lane Theatre by a man named George Barnett, an attorney's clerk, who for several months almost daily had been sending Miss Kelly amatory epistles, sonnets, acrostics, and other professions of his love. Barnett was tried and acquitted on the ground of insanity, and sent to the Bethlehem Hospital for the Insane. "While there, he composed an ode to Miss Kelly, but finally lost his love for her, and spent his time in addressing amatory poems to every young lady whose name and residence he could discover."

Beard* relates of Guiteau, that while in New York, shortly before he shot President Garfield, he became infatuated with the idea of marrying the daughter of a Fifth Avenue millionaire, and followed and annoyed with his attentions a lady whom he supposed to be this daughter, but who was another relative. In the West, he followed a young lady in the same way until he was finally kicked or horse-whipped by her father. Beard also records three other similar cases; the first, that of a man who for months annoyed with his ridiculous attentions the daughter of one of the wealthiest men of New York City; the second was a faithful and trustworthy clerk of a well-known merchant, who showed the same sort of foolish infatuation for his employer's daughter; the third was a man who persistently followed Miss Nilsson, the singer. These three men were all eventually sent to insane asylums.

While, however, erotomaniacs frequently select public characters for their unsolicited and obnoxious attentions, such is not always the case; their affections may be directed to almost any one that chance or accident throws in their way. Their attachments are sometimes fickle, and they are not always satisfied with one object of adoration.

I will first give a brief account of the crime and trials of J. C., as obtained from the newspapers and other sources.

J. C., about 28 years old, lived with his parents on the banks of the Susquehanna river. He shot and killed a good-looking young girl about 18 years old, employed in the family as a domestic. Later I will give his own statement as to the manner in which the crime was committed.

The affair created a great deal of excitement. J. C. was arrested, and was tried in October, 1881. The killing was admitted, the defense being insanity. He was convicted of murder in the first degree, and sentenced to be hanged; but in May, 1882, the Supreme Court granted a new trial, deciding that the judge, in his charge, erred in instructing the jury that "the presumption of sanity can only be overthrown by clearly preponderating evidence." The Supreme Court ruled that only "fairly preponderating" evidence was necessary.

The case was called again at the November term, but on motion change of venue was granted to another county.

On Monday, April 23, 1883, the new trial be-

*A Treatise on Insanity in its Medical Relations.

*Journal of Nervous and Mental Disease, October, 1882.

gan. Again a strong effort was made to prove the insanity of the prisoner, over twenty witnesses being called to testify to his past actions and the general repute in which he was held. Over thirty witnesses were called in rebuttal, and two weeks were spent on the trial, which ended with a verdict of guilty of murder in the first degree, the jury being out three hours. He listened to the verdict calmly, but his mother wept bitterly.

A motion for a new trial was made and subsequently was argued and overruled, the prisoner being sentenced to be hanged. The case was again taken to the Supreme Court, which refused to interfere, and the Governor appointed Tuesday, the 22d day of April, for his execution. Wearied out by the long litigation, C.'s father seems to have lost all hope of serving his son, but the mother never gave up. She went to the Governor's office personally, and her lawyers brought the matter up before the Governor and the Board of Pardons, asking for a respite of 60 days to give opportunity to introduce testimony as to the mental condition of the prisoner, and for argument.

From what I could learn, I infer that his father was a rough, uncouth sort of man, eccentric, or even more, but a man who had lived through a long life without committing any criminal acts. The mother stated that John was all right when he was born, and so far as she knows there was nothing the matter with him until he reached the age of sixteen, when he accidentally shot one of his hands and as a consequence lost some of his fingers. She dated the mental peculiarities from about that time. I think it somewhat doubtful that this had anything to do with it. It probably was simply a coincidence, although, perhaps, it may have assisted in developing what mental peculiarity he afterwards exhibited. A couple of years later, he had typhoid fever. These people lived in a peculiar way. The young fellow told me that his folks, as well as the rest of those living in this region, were known as "cornwhackers," which is something I suppose on the order of bushwhackers. His father and he were continually quarreling, and it depended on who got the shot-gun or the pistol first in the morning as to which should rule the house during the day. In one of these skirmishes, he received a severe wound on his head from an iron kettle in the hands of his father, the mark of which he showed to me. This occurred when he was 19 or 20 years old. He was noted as a strange character, not only in his immediate neighborhood, but also at Marietta and other places in that region. He was said to be a licentious man, and was called crazy by many people, although he was bright and shrewd enough in a great many things. He was always noted for his egotism, his habit of continually talking about himself.

The young girl, E. M., came to live with the family, from a neighboring town. John fell in love with this girl, as he had a habit of falling in love with almost any girl he met. As you will presently see, this is a point in connection with this case. He wanted the girl to marry him. He told me that she had promised to marry him, and explained how she used to tease him.

He gave the story of the murder in pretty much the way I give it to you. One morning he met the girl in the stable, and asked her if she was going to marry him. The girl replied that "she was not going to marry him or anybody else." He said, "If you will not, I will shoot you." She replied, "Shoot," and he shot her. He then shot at himself twice. Both the wounds were, however, only flesh wounds, and neither serious; one was on the sternum, and the other on the back of the head. He then went into the house and went to bed, where he was when his mother came and inquired for the girl. He said that he had killed her; that she was dead, and that he had killed himself, too. (*Sic.*) His father then went for an officer and had him arrested. He said to the constable that there was no use in arresting him, for he had killed himself. The officer replied that he had killed one, and that that was enough, and took him to jail.

As stated, the defense of insanity was used, but recognized experts were not, I believe, employed in the case. A number of physicians, however, testified to his insanity; others testified that he was sane. After conviction, efforts were made to respite him in order that an examination should be made of his mental condition.

Dr. H. E. Goodman and myself examined him twenty-four hours before the time set for his execution. I will give, as well as I can, a detailed account of our interview, and explain what I think to be the nature of the case. It was stated in the newspapers that he had heard that the Governor would not respite him, and that he had broken down. Dr. Goodman and I, accompanied by another physician, and a lawyer, went to the prison to see him. Looking through the opening in the door of the cell, we found him with a broom sweeping his cell in a fussy way. We went in and were introduced to him, without, of course, stating our object in calling on him. We found a rather good-looking man, about five feet ten or eleven inches in height, and very well built. He had led an out-door life. He had dark hair, dark black moustache, dark eyes, and a peculiar but not a bad-looking face. He was not a brutal-looking man.

He said he was glad to see us, and immediately continued, "Well, I am a pretty nice, and a good-looking fellow. Ain't I?"

We replied that we thought he was.

"Yes," he said, "I am; there is no doubt about it; and I am a pretty well built man, too."

We asked him how he liked his quarters.

"O! well," he said, "I am getting sort of used to them, but I should prefer an out-door arrangement of some kind."

Then, without leading, he passed to a subject upon which we were afterwards informed he constantly dwelt.

"You see," he said, "I am a good-looking man, and fond of the ladies; and they are very fond of me."

We learned that no matter on what subject he began to talk, he would in a little while invariably pass off to talk about the women or girls. His refrain was that he was fond of them, and they were fond of him.

In order to draw him from this subject, I said to him, "John, I suppose that you know that your end is near, and that you will probably die within twenty-four hours?"

"Yes," he said, "I guess so. I rather think I

will. The people seem to have made up their mind that they will get rid of me, but it seems rather hard in a civilized nation like this for the people to want to do such a thing."

We asked him, "if he was prepared."

"Oh, yes," he replied; "I am prepared. It is all right with Jesus." He then rattled off two or three verses of Scripture, and continued, "I am all right with the Lord! The Lord Almighty is for me."

Immediately, to our astonishment, he then said: "By the way, do you know how well I beat that fellow out of a watch?"

We expressed surprise.

"Yes," he said, "I took an old brass watch and burnished it up. I tried to beat another fellow, but he got ahead of me, and gave me one of these watches with a glass face; so I thought I would beat the next fellow that came along. Somebody came into the cell and I made a trade with him. I got his watch and ten cents to boot."

We asked him if he supposed that the Lord looked favorably on actions of that kind.

"Yes, I think he does. It is all right so far as that is concerned."

He then once more branched off to his favorite topic of women. All around his cell, he had fastened up cheap pictures, which had been cut from newspapers, theatre bills, and the like. He was much enamored with a very inelegant but striking picture of some woman performer in a traveling troupe. In reference to these pictures, among other things, he said: "Even if we cannot have them here alive, I would rather have them here this way than not at all."

We again got him off to another subject, by asking about the crime that he had committed. He gave an account of it in pretty much the way that I have given it to you. He remembered that he had killed her, but could not remember exactly how he came to do it. He remembered and he did not remember. He said very naïvely, "I am sorry they did not let me go. I had nothing against E. I am glad though that it is all right with the Lord, so that I can go to heaven and be with her. If I can be with her, I'll be satisfied."

We asked him about his father and mother.

"Well," said this strange being, "you know mother is nice. She is very good. Poor old soul, I pity her. I pity that woman; I just tell you I do. She is going on around here; she feels bad, and it almost makes me feel bad myself. But as to father, the old man and me could never hit it. It was always one or the other to be on top. We took a little shooting match one day. Even if it was my father, I thought I might defend myself, and I would take a pop at him if he did at me." On this occasion, he shot a piece off of his father's coat. In this connection he told me of his father striking him on the head with the iron kettle.

Suddenly he came back to his favorite topic. "You know," he said, "about these women who have been visiting me? They come around here, and think I am a pretty good-looking fellow, and get rather taken with me. You have heard of one of them, haven't you?"

We said we had not, but should like to hear about her.

He then mentioned the name of a well-known woman of the community, who either out of humanity or curiosity had visited him, as had also a number of other women. He said of this one: "I am in love with her, and she is in love with me; still she acted pretty mean. I wrote her a letter telling her that I loved her, but she never answered it; but I know that it is all right." (He had in fact written a number of letters to this woman.) He continued: "You know the women come here, and although I am so fond of them, they do act sort of scared. They sit this way," (getting on the edge of a chair and mimicking a half-frightened look). "They ought not to be afraid of me. A man who likes women as much as I do would not hurt them."

This will give you an idea of the character of the man. Of course, much more passed, but this will be sufficient. Before we left him we again tried to draw him to some other subject, and told him that we thought there was not a particle of hope of his being reprieved. He agreed to that, but thought it was a shame for them to act so to a "soft-headed fellow like him."

He spoke of his "spiritool" advisers, as he called them. He referred to one in particular. He said of this minister, "He came down here and picked up that almanac, and turned over the pages until he came to April 22d" (The day on which he was to be executed). "That," said he, "was a pretty nice thing for a 'spiritool adviser' to do; that was. He was a pretty brave man, too, for I felt like punching his head. He asked me if I did not want to make a speech on the scaffold; if I did, he would take care of me. The idea of my making a speech and getting into all these nasty newspapers, that are all down on me, anyhow. I told the sheriff that he wanted me to make a speech, and that I would not do it; and the sheriff told me that my head was level, and I think it is."

He then again went on to speak of the women. We then said "Good-bye." He said, "Good-bye. I am a pretty good sort of a fellow; better than those cornwhackers down there."

That is about the last that he said to us.

He had no hallucination of hearing or sight that could be made out.

He told one yarn, which was probably one of the funny, or half-smart things of which he was full. He said, "Some fellow came around here one night about seven feet six, and looked down through that hole (the opening in the door) and said, 'John, I guess you are going to be hung,' and then got out. That was a pretty thing to do in a civilized nation." There was, however, no evidence of hallucination.

This man either suffered from monomania or imbecility, or he was perhaps on the border line between monomania and imbecility. He was very vain and egotistical, a peculiarity that had been noted by every one who had known him. He had very exalted notions of his own worth, strength, and good looks. In addition, he had some tendency to persecutory ideas with reference to others. He was certainly not a case of true melancholia, as I saw stated in the paper-book of the plaintiff in error to the Supreme Court. If depressed at all, he was subject to logical, or rather illogical, depression, rather than to emotional depression, as is the case in true melancholia.

He was an illustration of one form of that phase

of monomania termed *erotomania*, which I have explained. He could not be kept from the subject of women. Was he shamming for effect? I think not, although to some extent he may have affected silliness of behavior. He may have been informed of our errand. Both Dr. Goodman and myself made allowance for this possibility.

My description of his remarks may make them seem irreverent, but such was not the case. They showed an utter imbecility, an utter want of appreciation of his true condition, an utterly foolish and silly frame of mind.

It is one of the most difficult matters to decide as to the responsibility of the individual in cases of this kind. It is questionable whether some cases of monomania are not responsible for the commission of some crimes. The line cannot be drawn by deciding that the case is one of some form of insanity, but each individual case must be studied on its own merits. The community is naturally always very much excited in such cases. It is not in a condition to listen to anything like reason. There were even threats of lynching this miserable man if he should be respited.

Most of those who had seen much of him thought that he was insane. I learn from the papers that he marched to the scaffold and died, as most monomaniacs do, without any sign of fear.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Stated meeting, August 17, 1885. The President, C. T. Parkes, M. D., in the chair.

A Case of Ovariotomy

Was reported by Dr. C. T. Parkes, as follows: In Feb., 1885, the patient, Mrs. R., aged forty-three, ten children, came under the care of Dr. O'Connell, of Ponca, Nebraska, who diagnosticated ovarian tumor. Dr. Parkes was requested to perform ovariotomy. He found the patient in fair condition generally, hopeful and clear-minded. The abdomen was glistening with distension. Fluctuation was extremely well-marked in all directions and in all positions of the patient. No resonance anywhere. No umbilical hernia. Her trouble dated from August, 1884, when a small tumor was perceptible in the right side. It gradually increased in size until January 17, 1885, when local peritonitis set in and was followed by rapid distension. Ovariotomy was done March 24, 1885. The patient had been placed in a bright light and an incision four inches in length made in the abdominal walls, midway between the umbilicus and pubes, to the peritoneum. There was no peritoneal fluid, but fortunately the bright light enabled me to distinguish between the peritoneum and the sac of the tumor, so closely were they applied to each other by adhesions. The adhesions were broken down so far as the hand could reach. A trocar was next plunged into the tumor and about eighteen quarts, or about 36 pounds, of a dark, sanguineous fluid evacuated. The sac was enormously distended and very thin. After the most of the contents were drawn off, the opening made by the trocar was closed by Nelaton's forceps. The sac was still adherent extensively, laterally and posteriorly. These were destroyed as completely as possible, and yet it was impossible to draw the sac through the opening, or to reach the deeper adhesions to the pelvis and flanks. Finally a free space was found in the right iliac fossa, the sac turned up and the pedicle found and secured. The greatest difficulty was found in separating the sac from the intestines, which were universally adherent to the posterior surface of the sac, and could only be reached by turning the tumor upwards after division of the pedicle. A firm, broad adhesion to the stomach at the top of the cyst could not be separated, so a portion of the outer wall of the cyst, corresponding in size to the adhesion, was dissected from the tumor, and in that manner the entire tumor was finally removed. The pedicle was about two inches long and very slender, and came from the right side of the uterus. It was noticed in the specimen exhibited that the sac was almost entire, and that it was not smooth and glistening, but rough from the adhesions, and at lower part there was an indurated mass about the size of a large orange. The sac and mass together weighed but three pounds. There was a vast area of oozing surface from which the adhesions had been torn, yet very little blood was lost. The abdominal cavity was thoroughly sponged, a drainage-tube introduced, and the wound closed by six silk ligatures.

The length of the incision, after the removal of the tumor, was but two inches. The patient progressed favorably until the fourth day, when she was attacked with severe and persistent vomiting, rising temperature and pulse. Stercoraceous vomiting ensued and increasing exhaustion, until her death, on the sixth day, pointed toward bowel obstruction.

The points to be noticed in this case are the great extent of the adhesions, the only clear space being in the right iliac fossa, the only way to reach them being to ligate and separate the pedicle and then turn the sac upwards; the small size of the pedicle to such a large tumor. It seemed to be approaching the conditions of a free ovarian tumor described by Mr. Doran, who explains their presence by atrophy and abruption of the pedicle taking place when there are very vascular adhesions of the tumor to other parts, through which nourishment is carried on. It was also noted that this patient went along all right for five days, then symptoms of intestinal obstruction set in. The question was raised, whether it is not the urgent duty of the surgeon in such a case to reopen the abdominal wound, and search for the seat of the obstruction and remove it.

A Case Requiring Battey's Operation

Was next detailed by Dr. Parkes. Miss M., age 17, single, an American, had suffered greatly from pain referred to right iliac fossa, increased during menstrual periods, for one year previous to placing herself under his care, January, 1885. She was already an invalid. Examination *per rectum et vaginam* disclosed retroversion of the uterus, accompanied with a dislocation of the right ovary into the Douglass *cul de sac*. Medical treatment having failed, Battey's operation for the removal of the prolapsed ovary was done June 2, 1885.

Nothing unusual occurred during the operation, and the patient convalesced rapidly. The temperature never rose above 99°. The dressing placed upon the wound was the dry dressing consisting of iodoform, antiseptic gauze and a layer of absorptent cotton. This dressing was not removed until the seventh day, when the stitches were removed. The line of cicatrix was perfect throughout. There was no formation of pus. The blood around the stitch-holes was dry and scaly. The case was remarkable, principally, from the absolute freedom from any discomfort during the recovery from the operation. It was the first example of dry wounds Dr. Parkes had ever seen. The patient was out in three weeks. The uterus was not fastened in its new position, and is slightly anteflexed, but not anteverted. The morbid specimen exhibited is the ovary much enlarged with two small parovarian cysts developed on it.

A Case of Double Ovariotomy

Closed the series of cases presented by Dr. Parkes. Mrs. P., æt. 44, and had borne five children. She complained of a tumor growing for the last two years over the situation of the gall-bladder. February 15, 1885, Dr. Parkes made an exploratory operation, and after cutting into growth, out popped this biliary calculus, about one inch long and bean-shaped. Nothing further was done, and the tumor began to disappear. However, during the manipulation of the abdominal walls he discovered two small tumors in the pelvis, in the region of the ovaries, which were supposed to be ovarian growths, but were not disturbed. But they rapidly grew in size, and were removed by laparotomy on June 16, 1885. The bowels had been moved two days previously. The abdominal incision disclosed the larger of the two tumors now shown, the larger filling the anterior inlet of the pelvis and held down by slight adhesions. These were broken down and the mass removed. It was found to be the degenerated right ovary. The pedicle was extremely short, and was with difficulty secured. It was tied, divided, and the stump dropped. Likewise the left ovary was removed and found to be degenerated. The tumor being smaller and pedicle longer, no difficulty arose. Finally, in sponging, quite free bleeding was noticed from the right pedicle. It was again transfixed close to uterus, and all hemorrhage ceased.

It was noticed that the sigmoid flexure of the colon was distended with fæces, and this condition was remarked as unaccountable, from the fact that free catharsis had been obtained only two days previously. The patient did nicely for ten days after the operation, with the exception that no action of the bowels could be secured by medicines or enemas. A careful digital examination revealed, high up in the rectum, a stricture which could not admit the end of my index finger. The slight opening was surrounded on all sides by a thick, dense deposit of abnormal growth. The question of relief seemed to stand between forcible dilatation of the stricture and the establishment of an artificial anus. July 30, he dilated the stricture so as to admit three fingers in a cone shape. The tissue was very dense. It broke down with difficulty, and the induration extended up the bowel quite two inches. After this was done the scybalous mass was easily removed. By the next day the bowels had moved several times, freely, and tympany disappeared. As Dr. Parkes had to leave the city July 5th, the patient was left in the care of Dr. R. G. Bogue, who subsequently told him the patient had died suddenly on July 10th, with symptoms of perforation of the bowels. Two inquiries arise:

1st. Is it not well to examine the rectum thoroughly before operations, in all cases?

2d. Would the establishment of an artificial opening, as soon as the nature of the obstruction was determined, have given a better result in the case reported?

Dr. Parkes also exhibited a specimen of epithelioma of vulva, which he had removed by Paquelin's cautery.

Dr. Etheridge opened the discussion by asking how far we could go in removing portions of the intestine in cases of obstruction. He said that he had recently had a trying experience in a case of ovarian tumor, in which, after the operation, the patient reacted well, but in forty-eight hours vomiting came on, which soon became stercoraceous and the patient died. On post-mortem examination, the whole of the large and most of the small intestines were greatly distended with flatus. A short piece of the small intestine, just where it entered the large one, was collapsed, and with great difficulty could any of the flatus be forced through it. He asked the author of the paper if he would have had the courage to have removed this portion of the intestine.

Dr. Franklin H. Martin said he had been very much instructed and entertained by Dr. Parkes' well detailed report. It had impressed him with three points or lessons that were dwelt upon in a recent article by A. Vander Veer, M. D., of Albany, N. Y., in the July number of the *American Journal of Obstetrics*, citing "personal observations on the work of Lawson Tait," at his private hospital, in Birmingham, England. These three points, which to his mind explain, to a great extent, the wonderful results of that great operator, are:

1. Cleanliness, pure air, and sunlight.
2. Efficient good-looking nurses.
3. Close personal supervision, and attention to after-treatment.

In the first case Dr. Parkes reported to-night that good light had saved him from going directly into the sac of the cyst in attempting to enter the peritoneum. This case also, he suggested, might have fared better had he been present to have given personal attention to the movement of the bowels, thus, possibly, removing the obstruction which was apparently present. In the third case, if personal attention had been given to the bowels sooner, the obstructions due to the stricture might have been removed and the ultimate result been more favorable. Here the nurse was at fault. Again, in the third case, if personal attention had been possible, the early operation of artificial anus, as Dr. Parkes suggested, might have influenced favorably the ultimate result.

Dr. Weller thought that dilatation of the rectum was the only feasible method of relief in the case in which a malignant growth was formed in the lower bowel. An operation for an artificial anus would have been difficult under the circumstances.

Dr. Stevenson asked why not open the sigmoid flexure and remove the accumulation from it at the time of the operation?

Dr. Parkes closed the discussion by saying he would remove a portion of the intestine if it presented the only way of saving the patient's life. If in a few days after the operation symptoms of obstruction should come on, he would reopen the wound and seek for the seat of the trouble. He said that his theory of the best mode of procedure in these cases was gaining ground in the profession every day. Dr. Hamilton, of New York, lately reported a case of a gun-shot wound of the abdomen, in which there were eleven perforations of the small and four of the large intestine. These were sewed up and the patient recovered.

The cause of the constriction in the case reported by Dr. Etheridge was probably due to an obstruction of the arterial supply to this part of the intestine, causing it to contract. Little good would come from an operation in this case. He thought an artificial anus might have been made in the second case referred to in his paper, though the bowel was distended. In these cases only a small opening was necessary. This might have prolonged the patient's life a short time. The cause of death was perforation of the bowels, resulting from an ulcer incident to the dilatation of the rectum. He generally used saline cathartics to open the bowels. He would not have been justified in removing the accumulation from the sigmoid flexure at the time of operating, on account of the additional shock to the system it would have caused.

Observations on the Cause and Treatment of Infantile Eczema and Allied Eruptions,

was the subject of a suggestive paper read by Henry T. Byford, M. D. He said, in the winter of 1880 he had been called to attend Mrs. R. in her fifth confinement. Two of her other children were dead, and two more, apparently healthy at birth, had died in convulsions before they had completed one year of life. Both of the last two had suffered from scabby eruptions, and had become somewhat emaciated but had not been considered syphilitic. The child born at this time, seemingly healthy at first, soon broke out with what appeared to be an ordinary eczema pustulosum. This eruption occurred on the scalp and on different parts of the body. The child suffered from progressive emaciation, and at the age of three weeks it would easily have been mistaken for a case of struma, to be treated with cod-liver oil. The patient was quickly relieved by calomel in minute doses and mercurial inunctions.

The next case referred to was that of Augustus G., seen first in the summer of 1876. The child had pustular eczema of the scalp, great nocturnal restlessness, and suffered from progressive emaciation. There was no cause to suspect syphilis from the appearance of the child, but the father acknowledged to what seemed to be a perfectly cured attack of syphilis. The eczema rapidly disappeared, and the infant gained in flesh upon calomel powders and mercurial inunctions.

In contrast with these syphilitic cases, he next mentioned the case of E. H., a child one year of age, fat and well nourished, with no possibility of a syphilitic taint, but suffering from an eczema of the head, which spread over the body in patches. Prolonged local treatment had not improved it. The disease soon disappeared under the use of one-fifth grain powders of calomel, given twice a day, and an ointment composed of a drachm of carbolic acid in an ounce of oxide of zinc ointment. The child had been over-fed, and was put upon a restricted diet. There was no return of the disease.

The next case was one in which the eruption invaded the eyelids and caused great conjunctival sensitiveness. By the use of quarter-grain doses of calomel, given twice a day until a laxative effect was produced, then once a day, combined with the external application of carbolized oxide of zinc ointment and a borax eye-water, the condition of the patient was soon greatly improved.

He had succeeded in relieving many other severe cases of eczema by the use of calomel, and it made no difference on what part of the body the eruption occurred or what the condition of the patient was otherwise.

That eczema so frequently occurs in infancy, the large size and great activity of the liver in early life, and the striking action of calomel, had led the author to associate indigestion with infantile eczema as cause and effect. In syphilitic cases the alterative powders often produced an amelioration in the skin trouble sooner than they could through their direct action upon the blood poison. In all cases it is important to regulate the diet.

He knew of no authority who had considered derangements of the liver, and its accompanying digestive disorders, as the chief cause of eruptions of the skin, or who had recommended calomel as the chief remedy for its cure.

As calomel produced such prompt relief, and as improvement of digestion usually followed rather than attended the action of the remedy, one is led to believe that the cure is brought about not merely by improving digestion, but by a removal of waste irritating matter from the system, and from the great efficiency of mercury over other laxatives. He believed that the irritating materials are not only in the retained fecal matter, but also in the blood—the products of imperfect digestion, assimilation and excretion.

He was led to the use of calomel in eczema from noting its good effect in cases due to syphilis; and as these patients improved so well under its use, he next tried it in cases where syphilis was only suspected, and then in all cases.

The usual dose was from one-quarter to one-eighth of a grain powder, given twice a day, the dose to be reduced if too great irritation of the bowels was produced. In cases of children over two and a half years of age, in order to avoid salivation, he usually gave purgative doses of calomel every six or eight days, and trusted to diet and other remedies in the meantime.

In the discussion, Dr. E. J. Doering said he had not used calomel in eczema, but had had good results from the use of corrosive sublimate. He intends to use calomel, after this, in such cases, and he thought nothing better could be found to use in chronic cases.

Dr. J. Zeisler remarked that he was very much interested in this paper, and, especially, to hear that calomel was useful in eczematous skin diseases. He had always held the view advocated

by Hebra, that eczema was caused by external causes and required external applications for its cure. Calomel might be of use in cases due to syphilis. He would not use blue ointment on young children. He asked whether it would not be best to use some external application in cases where there were thick masses of crusts covering the diseased part, and also whether the author of the paper had found salicylic acid useful in this disease.

Dr. C. W. Purdy thought retained excreta a cause of eczema, and called attention to the close relation existing between the intestinal tract and the skin, the condition of the one affecting the other. He had seen cases cured by the use of calomel, and would favor this treatment.

Dr. J. A. Robison said that Dr. Byford had found mercury beneficial in syphilitic and non-syphilitic cases, probably because given in small doses it was a general tonic, as iron or cod-liver oil, increasing the number of red blood corpuscles and enriching the blood. Thus it counteracted any dyscrasia present.

Dr. Byford concluded by saying that Hebra was doubtless right in saying that eczema is caused often by external causes, but in some cases it was clear to him that the disease is due to causes arising within the system itself. In later years Hebra had modified his ideas of this disease somewhat. Although eczema could be cured by external applications, when so treated it is very apt to return. It is not so when removed by the use of calomel. External medication would often hasten the cure. He did not use salicylic acid. He believed that calomel in these cases acted as an agent causing eliminations, as well as being a tonic.

The Society then adjourned.

Two Cases of Removal of the Whole Tongue for Epithelioma: Remarks.

Mr. Berkeley Hill thus writes in the *Lancet*, July 18:

Excision of the tongue in cases of cancerous disease of that organ is undertaken by the surgeon with the view either of entirely removing the disease or of relieving pain. The following methods of operation have been suggested: (1) Excision of the whole or a portion of the tongue from the mouth; (2) removal after division of the lip and jaw; and (3) excision through openings below the jaw. The removal from the mouth by means of scissors when possible, as in the second case recorded, is the one which finds most favor at the present day, incisions for the removal of diseased glands being afterwards made according to the necessity of the case. Division of the lower jaw adds considerably to the risk of the operation, and is not performed unless it is not possible to reach the growth without, or unless the jaw is infiltrated by the disease. The submental operations are rarely performed.

For the following notes we are indebted to Mr. Bilton Pollard, surgical registrar:

Case 1. W. W., a man aged fifty years, was admitted to the hospital on March 16, 1885. He stated that he had had pain in swallowing during the last seven months, and that he had noticed a lump beneath his chin for about three weeks. On admission the tongue was much enlarged, and the left side of it was the seat of a hard new growth; there was no ulceration of the dorsum or the side of the tongue, but the tongue was almost immovably fixed to the floor of the mouth, and the submental tissues were much indurated. There were three enarlged glands beneath the left angle of the jaw.

On March 25th, Mr. Hill made an incision in the middle line of the lower lip down to the bone, and dissected off the labial tissues from the front of the lower jaw; he then divided the lower jaw in the middle line, and, finding the bone was implicated, he divided it again on the left side just in front of the masseter muscle, and on the right side just beyond the first bicuspid tooth. Mr. Hill then commenced to free the tongue and submental tissues from the superficial tissues of the neck; but as the breathing became embarrassed, owing to escape of blood into the pharynx, he opened the trachea and put in a tracheotomy tube, through which the anæsthetic was administered during the rest of the operation; a sponge was placed at the back of the pharynx. The tongue and sublingual tissues were then snipped away from the mere superficial structures, first on the one side and then on the other, with scissors; the right lingual artery was seen before it was cut, so it was first seized with a pair of forceps, and then tied; the left lingual artery was divided, but it was quickly seized with the forceps, and tied. Both sides being freed, the tongue was then separated from the hyoid bone on the dorsum, and was pulled strongly outwards, whilst the snipping with the scissors was continued from the dorsal surface till finally all the structures beneath the tongue were removed as low as the hyoid bone, the tendon of the left digastric muscle being removed with the growth. One enlarged lymphatic gland lay close to the sheath of the carotid artery, and in its removal the left facial was wounded, but the bleeding was quickly arrested. The edges of the wound were brought together with six wire sutures, and dressed with iodoform and iodoform wool. The parts removed consisted of the portion of the lower jaw from the right canine to the first left molar tooth inclusive, the entire tongue, both sublingual glands, the left submaxillary gland, and a chain of lymphatic glands which reached lower than the level of the hyoid bone. The right half of the tongue was normal. Microscopical examination of the left half of the

tongue and submaxillary gland showed them to be largely occupied by fibrous tissue and small round cells; in many places tubes of squamous epithelial cells ramified through the tissue; in the more superficial parts the cells were distinctly epithelial and had dentated borders, but in the deeper parts the cells were smaller and were contained in areolar spaces, and resembled rather the arrangement of cells in carcinoma. After the operation the patient was fed by nutrient enemata, and in the afternoon of March 26th (the day after the operation) Mr. Hill passed a tube through the mouth into the stomach and some "egg-flip" was administered, the patient being fed in a similar manner afterwards. The temperature usually ranged between 98.4° and 99.6°, and reached 101° on only one occasion and 100° on two. The tracheotomy tube was removed on the thirteenth day after the operation. An enlarged lymphatic gland was detected in the right submaxillary region on the nineteenth day, and this, with two others that after removal were found to be normal, were excised on the twenty-first. The only difficulty and trouble the patient experienced after the operation was from mucus collecting in his mouth and throat and from the irritation of the ends of the divided lower jaw. The patient began to feed himself by the mouth on the twenty-eighth day, and expressed himself as being quite freed by the operation from his former constant pain and discomfort. He was discharged on the forty-sixth day after the operation; two glands could then be felt in the neck.

Case 2. *Squamous Epithelioma of Tongue; Removal with Scissors; Temporary Relief; Death eight months later from Recurrence.*—G. L——, male, aged fifty-five, was admitted into the hospital on April 1st, 1884. He had been a great smoker, had had syphilis thirty years ago, and white patches had existed on his tongue for three years. On admission there was an epitheliomatous ulcer on the anterior third of the middle of the tongue, and behind it there were white patches on the dorsum of that organ; the lymphatic gland beneath the genio-hyoid muscle and those at the angles of the lower jaw were enlarged. Mr. Hill removed the whole tongue with the scissors according to Whitehead's method; four arteries bled freely on the right side, but only one on the left; they were easily secured and ligatured. The stump of the tongue was fixed up by a ligature passed through its base. The temperature reached 100.4° on the evening of the operation and 100.6° on the following day, and afterwards remained normal. The patient made a rapid recovery, and was discharged on the thirty-sixth day after the operation. Four months and a half later, he was readmitted with recurrence in three glands, which were about the size of walnuts. There was one in each digastric triangle, and another at the anterior border of the right sterno-mastoid muscle at the level of the cricoid cartilage; these were removed, and the wounds were dressed with Listerian antiseptic dressings; on the right side the submaxillary gland and anterior belly of the digastric muscle were implicated, and were accordingly removed with the glands; the internal jugular vein was implicated by the growth in the neck, so it was clamped and tied above and below, and about an inch of the intervening portion was removed with the glands. The temperature reached 100.6° on the first and 101° on the second day after the operation, and afterwards remained normal. The patient made a rapid recovery, and was discharged on the fourteenth day after the operation. He was admitted again three months later with return of the growth in the floor of the mouth, in the lymphatic glands behind the right angle of the lower jaw, and in the right side of the neck, where there was a large tumor which had broken down in the centre and was suppurating; the abscess was opened, and the patient was temporarily relieved, but he died of exhaustion and bronchitis five weeks after his last admission to the hospital.

Remarks.—In the first case, that of cancer of the tongue and floor of the mouth, the operation, which was very extensive, was undertaken with the sole view of relieving pain and delaying the death of the patient by exhaustion. So far it was very successful, though as a means of ridding the patient of his disease it will in all probability prove ineffectual, notwithstanding that the whole of the sublingual tissues and lymphatic glands were removed. The ease with which, after division of the jaw, it was possible to perform such an extensive operation with a pair of scissors was worthy of note; the vessels were either clamped before division or at once picked up afterwards, and so there was very little loss of blood. In the second case of removal of the tongue the entire organ was removed through the mouth by the scissors, according to the plan advocated and so ably practised by Mr. Whitehead. In the case now recorded, Mr. Hill extirpated the whole tongue with the greatest ease, and with but very slight loss of blood; and, provided the operator has a good assistant, it is difficult to understand the great and even fatal loss of blood which has occurred in, at least, one recorded case. This operation reduces excision of the tongue to the level of other major operations; the surgeon deliberately cuts away the whole of the diseased structures, and when he divides a vessel he treats it as in other situations by tension or ligature; the tissues are not bruised nearly so much as by the écraseur, and consequently there is much less sloughing on the surface of the stump, and less liability to septic infection afterwards. There is also less, in fact practically, no liability to secondary hæmorrhage after Whitehead's operation. During two years that Mr. Pollard was resident surgical officer to the Manchester Royal Infirmary, he witnessed the removal of many tongues with the scissors by Mr. Whitehead and his colleagues. In only one case was there hæmorrhage afterwards, which occurred from a small vessel which bled when the patient was recovering from the shock of the operation.

Case of Tpyhoid Fever Complicated by Tetanus, with a Brief Review of other Recorded Cases of this Complication.

Dr. Henry M. Fisher thus writes in the *Med. Times:*

S. C., æt. 34, colored, had for about a week before my first visit to him experienced irregular chills, slight epistaxis, and sore throat, and had been languid and restless at night. I was called to see him March 21, 1884. I found

that he had high fever (temperature 105° F.), and that there was much tympanites, but was told that he was decidedly constipated. At the time of my visit his nose was bleeding freely. Ordered cinchoninæ sulphat. gr. x, at 7 and 9 a. m., and acid. muriatic dilut. gtt. v, every three hours.

March 22. Pulse 100; temperature 105°. Tympanites undiminished. Very free epistaxis.

March 23. Pulse 92, and weak; temperature 102.2°; tongue moist; mild delirium. Says that he sees "horses, dogs, and elephants." Epistaxis continues, and he has had some vomiting; abdominal wall tender to the touch; splenic dullness obscured by extreme tympanites; no movement of the bowels. Ordered calomel, gr. vi, and for muriatic acid substituted acid. carbolic. liq., f.℥i, tr. iodin., f.℥ij, to be given in drop doses every two hours.

March 24. Pulse 96, and fuller, temperature 103°. Complains of much abdominal pain. The calomel did not operate, and his intestines are greatly distended with gas. Very free epistaxis last night. Ordered calomel, gr. vii, sodii bicarb., gr. x, and increased dose of iodine and carbolic acid to two drops.

March 25. After an injection yesterday evening, patient's bowels were moved six times. He was less delirious during the night. Temperature 104.3°. Marked increase in hepatic and splenic dullness. Tongue still moist, but lips dry. Ordered cinchoninæ sulphat., gr. xv, at 5 and 7 a. m.

March 26. Pulse 92; temperature 102.4°. Marked double vision this morning, and had muttering delirium during the night. No further movement of the bowels. Abdominal pain still complained of. Calomel and soda repeated, and ordered quininæ sulphat., gr. viii, at 4, 4.30, and 5 a. m.

March 27. Pulse 88; temperature 102.8°. Expectorated some blood this morning, which appeared, however, to have come from posterior nares. Calomel again failed to operate. Appetite has improved.

March 28.—Was called to see patient at 6 a. m., and found that for about two hours he had been in convulsions. Pulse 84; temperature 99.2°; respirations about 10 in minute, and breathing of Cheyne-Stokes type—one long, sighing respiration being followed by several shorter and shallower ones. There is complete unconsciousness, with marked clonic spasm of the muscles of the upper extremity and of the facial muscles, with only slight intervals of comparative muscular relaxation. There was very decided tonic rigidity of the masseter muscles (trismus). Applied cold to the head by means of Leiter's tubes, and directed the cap to be kept constantly applied. Four hours later his condition had changed very little, except that the paroxysms were even more violent. His eyes were wide open, and he had a startled, frightened look, but appeared to be almost if not quite unconscious. There was marked opisthotonos. His jaws could not be separated sufficiently to introduce food or medicine by the mouth, so I ordered him milk and beef-tea per anum, also chloral hydrat. gr.xx every three hours by enema. I also directed two ounces of blood to be removed by leeches applied to each mastoid process.

In the afternoon I found him somewhat quieter, and was told that he had slept a little. The tetanic contractions were still, however, very marked. Gave atropinæ sulph. gr. $\frac{1}{100}$ hypodermically.

March 29.—Slept a little last night, and this morning consciousness has returned and all the tetanic rigidity and spasmodic movement have passed away. Leiter's tubes were removed, having been used for twenty-four hours with hardly any interruption. His temperature was normal or subnormal, and after this there was no further febrile reaction. His strength returned slowly, and he was very nervous and irritable for several weeks. In six weeks or two months, however, he was able to return to work.

Among the nervous complications of typhoid fever, tetanus would appear to be one of the rarest. Very frequently it is observed that tonic spasm or rigidity affects certain groups of muscles in the course of the disease; but general tetanic paroxysms are seldom observed, or at least have been seldom noted.

Duchek* reports a case of typhoid fever in which there was hyperæsthesia of the entire cutaneous surface, slight ptosis of the right eyelid and dilatation of the right pupil, fibrillar twitchings of the facial muscles, deviation of the tongue, and tonic spasm of the cervical muscles, at first confined to the right side. Later, trismus and opisthotonos occurred. Death occurred on the fourteenth day of the disease.

Girerd's† case occurred during apparent convalescence from a severe attack of typhoid fever. On the *thirty fifth day* from the onset of the disease severe epistaxis occurred. This was followed by paresis of the right side of the body and "paralysis of the pharynx." The patient presented tonic contractions of the facial, dorsal, and abdominal muscles. He was treated by galvanism to the spine and chloral by enemata, and appeared to be improving, when, through some mistake, a toxic dose of morphine was given him, and he fell into a comatose condition, and died on the seventh day after the first occurrence of the tetanic symptoms.

Simoneau‡ records one fatal case; and Fussell§ records one in a girl of 18 during convalescence in the third week, and another case, in which tetanic convulsions occurred—also during the third week—which ended in recovery. J. Fowler‖ records a similar fatal case, which was ushered in by profuse epistaxis. Dieterlen¶ records the case of a child who presented, on the fourteenth day of an attack of typhoid fever, stiffness of the limbs and neck, and on the fifteenth tetanic rigidity of the whole body. On the twenty-first day general convulsions set in (epileptiform), attended with a fall in temperature. These convulsions recurred on several successive days, but the child ultimately recovered.

¶Revue Médicale de l'Est, Nancy, April 1, 1884.

Riberolles* records a case of a patient who, on the twentieth day of an attack of typhoid fever, was seized with violent delirium, stiffness, and pain on pressure over the muscles of the back and neck, and who developed on the thirtieth day marked opisthotonos, attended with "choreic movements of the lips and hands." With the onset of the opisthotonos a sudden fall of temperature was noted (from 104.6° F. to 98.2° F.). The day following, there was marked spasm of the facial muscles; his pupils, which had been dilated, became contracted, and he died in a state of profound coma. The autopsy revealed ulcerations of Peyer's patches in process of cicatrization, engorgement of the cerebral sinuses and of the vessels of the dura mater, thickening of the arachnoid, three or four reddish patches (ecchymoses) on the surface of the brain, with effusion of fluid into the ventricles, thickening and opacity of the membranes of the cord, with reddish patches on its surface, as well as on that of the medulla oblongata. There were also signs of congestion of the substance of the spinal marrow and medulla oblongata.

It will be noticed that in the case just mentioned, as in my case, the tetanic spasm was ushered in by subsidence of the fever. Liebermeister has called attention to the great depression of the body-temperature which often attends the development of severe nervous complications in the course of typhoid fever, particularly when they occur at about the middle of the second or beginning of the third week. He attributes this phenomenon to an excessive irritation of the heat-controlling centres; but undue stimulation of the vaso-motor nerves, inducing contraction of peripheral blood-vessels, might also, I think, account for it. In the case of Riberolles there was inflammation of the spinal as well as of the cerebral meninges, and congestion of the substance of the cord and medulla oblongata. This is the only observation that I have been able to find of the condition of the cord and its membranes in a case of typhoid fever which was complicated by convulsions of tetanic type. It seems probable, however, that in all such cases which ended fatally we should find marked evidences of *spinal* meningitis, or at least of *congestion* of the *spinal* meninges. We may, of course, call *reflex irritation* to our aid to explain the development of the tetanic spasm in these cases. We have a central nervous system already in a state of abnormal irritability, and we have a localized lesion in the intestinal ulceration. If, however, this intestinal ulceration were really the exciting cause, we should, I think, expect to see the spasm developed at a much earlier period of the disease than is usually the case, and not at the stage when, in the great majority of cases, the intestinal ulcers are beginning to heal.

Vesical Explorations.

Dr. P. S. Connor, of Cincinnati, Professor of Surgical Anatomy and Clinical Surgery, Medical College of Ohio, Surgeon to the Good Samaritan and to the Cincinnati Hospitals, read before the Ohio State Medical Society, June 4th, 1885, a paper on "Vesical Explorations." He opened by saying, morbid conditions of the bladder may or may not be easily diagnosticated. Endoscopic examinations, of which so much had at one time been expected, have proved to be of little value, though much more satisfactory in the female than in the male. He considered all the numerous modes of exploration which he thought should be supplemented by urinalysis, chemical and microscopical examinations. Digital examination, systematized by Sir Henry Thompson, he thought, affords information of the highest value.

By the ordinary perineal section the membranous portion of the urethra is opened, the prostatic portion of the canal is dilated, and the finger is pushed into the bladder. By this means the finger tip can be brought in contact with every part of the bladder, and the mucous surface can be palpated, its irregularities noted, the present location, size and character of a growth ascertained, and a stone or foreign body in the urethra. In a recent case of the doctor's, the bladder was as thoroughly explored as if done post mortem. The objection is made that the operation does not answer in fat subjects; where the perineum is deep and the prostate enlarged, it is difficult to reach the bladder. Yet in most cases the finger can be made to sweep its surface. The operation is a simple one, merely the ordinary extra-perineal urethrotomy upon a grooved staff, and is almost devoid of danger. Guyon and certain French surgeons advocate the supra pubic operation. The author thought the advantages of exploration in the perineal operation much greater. For every reason, both as respects diagnosis and treatment, digital exploration should always be made when the other more ordinary and longer practised methods of examination have proved insufficient. In very young children, lateral rather than median urethrotomy should be made, since such an operation does not increase the danger to life, and relieves the surgeon of the trouble, at times quite considerable, of dilating the prostatic portion of the canal.

Dr. Holland spoke of rectal examination and in favor of the use of Sims' speculum of a large size. He thought it a rather bold procedure simply for diagnosis, especially in private practice.

Dr. Joseph Ransohoff, of Cincinnati, reported a case in which he had made the operation, and spoke recommending it.

Dr. Conner maintained that in many cases we are left entirely in the dark and cannot make a diagnosis. He has made at least 100 operations, and in not one case was death due to the operation. For himself he would much rather be subject to the operation than to be drugged as some are. He has been much surprised to find with what ease the bladder can be explored.

—An inhalation for coryza is recommended in the *Union Medicale* by Dr. Hager, composed of pure carbolic acid, one hundred and fifty grains; ammonia water, three drachms; alcohol, one ounce; distilled water, five drachms. A piece of cotton saturated with this mixture is placed in a wide-mouthed bottle, and the vapor is inhaled.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——An instructive article on pneumonia in young children, by Dr. L. Emmett Holt, of New York City, appears as a neat reprint by the Trow Printing Co. It is particularly full on therapeutics. Of all drugs he considers opium the best.

"It quiets the restlessness, relieves the pain and the cough, and, perhaps more important than all, sustains the nervous system under the strain which the disease produces, and in this way seems to exercise a beneficial effect upon the inflammatory process. I have found the tablet triturates of morphia, $\frac{1}{30}$ grain, a very eligible preparation; one may be given every two or three hours to a child a year old. Of late, I have used a great deal, and have come to prefer the tincture of opium and ipecac, or the liquid Dover's powder, to any other preparation of opium; it may be given in drop doses at the same intervals."

With this he prescribes local applications, good nourishment, and sometimes alcohol.

BOOK NOTICES.

Transactions of the Medical Society of the State of West Virginia. Wheeling, 1885.

Transactions of the Louisiana State Medical Society. New Orleans, 1885.

As usual, the Transactions of the West Virginia Society contain a number of original papers, most of which contain valuable results from original research and observation. The venerable Dr. Trissell, of Wheeling, puts in an earnest plea for blood-letting *to the point of relief*, especially in puerperal convulsions. He says:

"I have never had a patient die from being bled too much, but I am sure I have let a good number die by following the fashions of the day and not bleeding them properly at the proper time.

"Blood-letting is one of the great and powerful remedies, and will accomplish results that nothing else will. I will not undertake to discuss the great subject, but would advise every one to study it for themselves; but so long as the present doctrine or fashion prevails in regard to blood-letting, I fear many of the profession will never understand much about it, for it is by practical or clinical experience alone that the subject can be understood and appreciated."

He believes that extensive blood-letting, even if of no special use, is almost always quite harmless.

Dr. C. C. Hersman gives the result of several experiments with paraldehyde as a hypnotic and germicide. His decision is not very favorable to it. He observes:

"Out of eleven cases selected, I can boast of but one happy result. In a few other cases I had some good and some bad results, occurring with the same patients. Also, we notice in most of the cases, the increase of dose seemed to add to the bad effect. In some cases I recorded pulsations, but took no notice of respiration.

"It is certainly a hypnotic, and while it may be safe, given in proper doses, we fail to notice any property which makes it equal to other remedies at our command. In testing it as a germicide I used the following:

℞.	Sugar (gran.),		
	Yeast (dried),	āā	gr. xx
	Paraldehyde,		℥j.
	Distilled water,		℥j.

Mix.

"I let the mixture stand one week in a warm place with no fermentation whatever. I believe paraldehyde to be a germicide, but do not know the minimum per cent. at which it will act as such.

"Finally, the taste of the drug is very disagreeable. A large quantity of water is necessary to dilute it for use, and the fact that it does not supply the demand already met by other agents, will, in my opinion, prevent its extensive use both in private and in hospital practice."

Other papers of interest are by Dr. D. P. Morgan, on operations in malignant diseases; by Dr. F. C. Evans, on the signs of death; and by Dr. T. A. Harris. The address of the President, Dr. George Baird, is an excellent and sensible review of professional relations.

The Louisiana Transactions also contain various articles of general interest. Those by Dr. Rudolph Matas, on "The Long Continued Fevers of Louisiana that Resist Quinine," and by Dr. I. J. Newton, on "Hemorrhagic Malarial Fevers," will attract attention by the description of rare forms of disease. Dr. A. G. Friedrichs has a suggestive article on the relationship of the teeth to the general system. The address of the President, Dr. R. H. Day, was upon the theme "Mission and Methods of Medicines."

Swallowing a Nail.

A correspondent in Georgia writes us:

"As an addition to the article in No. 24 of the Medical and Surgical Reporter, 'Swallowing a Safety-Pin,' and demonstrating the propriety of an expectant treatment and the efficiency of the *vis medicatrix naturæ*, I beg leave to report the following case of swallowing a six-penny nail: One Monday evening in May, 1885, a little boy, I. S. M., æt. two years, four months, swallowed a six-penny nail (two inches long), with which he was playing. The child did not seem to suffer any inconvenience, as he played as usual afterwards. No remedies were administered; only his usual solid food was given. On the following Wednesday morning the nail, enveloped in fecal matter, passed off without any trouble. The child remained in usual health!

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM*, which we publish.

It is, in fact, a supplement to the *REPORTER*, being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE LAWS OF MATERNITY.

The natural laws that through nature's voice command a woman to nurse her offspring, have been frequently written upon, and from all time and from all men comes the injunction that where possible the mother is the best wet-nurse for her child.

That many shirk this important duty, we know full well; and that many are not capable of giving proper nourishment to their babes, we know equally well.

This fact has called forth a most excellent article from the pen of Dr. Nathan Allen, which we find in the *New England Medical Monthly* for August. Dr. Allen, after bewailing the fact that the custom of employing stranger wet-nurses and using artificially-prepared foods is rapidly increasing in this country, and noting the dismal fact that the number of those who are physically and physiologically incapable of nourishing their young grows rapidly, asks why this condition of affairs exists, and endeavors to give an explanation.

He advances the theory that in order to have an harmonious whole, a body capable of performing *all* the duties for which it has been designed, there must not be (as there frequently is) an undue development, training, exercise or use, of any one portion of the body. This is sound physiology and sound hygiene. The fact that more than ten thousand gross of nursing-bottles are annually sold in the United States, bears dismal testimony to the fact that very many of the future supports of our glorious institutions are being deprived of that natural food supply from which great men and women are made.

That many mothers have imperfectly developed mammary glands, and that many are physiologically unable to secrete healthy milk, we all know, and we also know the reason. It is but necessary to walk about a large seaside hotel to find the explanation. On a "hop evening," we will see great numbers of children from seven (aye even from five) years of age upwards dancing about until the hand on the clock registers 10, 10.30, and even 11 o'clock; when, worn out in body,

they go to bed to repeat the same monstrous indiscretion on the first occasion that offers. These little girls, that are to be the future mothers, are not to be blamed; they know not what they are doing.

It is the diamond-decked, low-necked and fashionably-attired mothers, who sit admiringly by, their faces wreathed in smiles at the precocity of their youngsters, who are to be held accountable for the production of a race of non-nursing mothers. The constitutions of these "*little women*" are so undermined by their faulty rearing that they are utterly incapable, not only of nursing their offspring, but in many cases of conceiving and giving birth to children at all.

And this brings us to another evil bemoaned by Dr. Allen. He claims that the productiveness of American women is on the decline, and cites statistics to prove his statement. Two causes are assigned for this. First, a physical and physiological disability, brought about by the same causes that negative the nursing function, and, secondly, the purposive interference with the function of conception.

In fashionable life this last cause is undoubtedly very prevalent, and if we mistake not, is on the increase.

It is not fashionable to have large families, and to those who only half realize the responsibilities they assume when they enter the married state, a large family is too much care and trouble.

The physical disability can, in the majority of cases, be avoided by the proper bringing up of our children; the purposive prevention can be removed only when human beings are content to live in accordance with the laws of nature, and are willing to throw the mandates of fashion to the winds. Expediency is sometimes urged as a reason for interfering with conception, as when a man is too poor to support a large family. This argument holds good when a man is unwilling to live according to his means. Of course two men, with equal incomes, the one with five and the other with ten children, cannot enjoy the same measure of luxurious living; but we daily see proof among our most prolific citizens (the laboring classes) that an honest, industrious man can manage to supply a living for all the children that nature provides.

The better class of Irish Catholics always manage to get along, and as a rule they have large families. For two reasons—they are industrious and frugal, they work hard, have good health and normal functions; their church looks with disfavor upon unnatural efforts to prevent conception, so much so that when a distinguished theologian was recently told that the question had been asked how the increase in the family could be checked by artificial means, and his opinion on the subject requested, answered, "Tell your questioner to go to the devil and find out; he knows more about it than any one else."

We have recently read of a woman in France who has given birth to twenty-six children, and who now at the age of 67 works daily in the field with her husband.

While recognizing, with Dr. Allen, the neglect of these two prime laws of maternity, and while thoroughly realizing that upon a thorough recognition of her duties by the mother rests fundamentally not only the welfare of her offspring, but as a logical sequence the welfare of the state, we at the same time feel that we have only our artificial method of living to blame for this neglect.

We see a ray of hope in the dawning interest in the science of hygiene, which is becoming manifest throughout our country. It is but a few years since this interest was awakened, but it is growing strongly and surely. Let us cultivate it for the good it will bring to us.

SEWAGE DISPOSAL.

Time and again have we urged that the solution of the problem of the disposal of sewage is to be found only in the return of organic refuse to the soil from which it has originally been derived.

We may construct expensive sewers and drain into mighty rivers, but we are only constantly maintaining, what we should sedulously avoid, the prevalence in our vicinity of decomposing organic matter, furnishing, if not actually disease

per se, at least the conditions favorable for its reception and development.

We have already stated that in many parts of Europe, and in some places in our own country, the sewage has been successfully used as farm manure, and we have pointed out the value of thus utilizing it from an economic point of view. A practical suggestion in this connection is contained in the following quotation from the report of the Committee on Public Hygiene, etc., which we find in the *Pacific Med. and Surg. Jour.* for August. The chairman, Dr. M. M. Chipman, says:

"Each family to be supplied with the suitable closet vessels, one of which, with the twenty-four hours' accumulations, to be conveyed, before the family retires, to a place provided, outside of the locked apartments, where it would be accessible to the night workmen. The work to be performed between midnight and six a. m., during which time the street cars are but little used, and these could then be utilized for train cars, to be propelled within the city limits by the power best adapted to the circumstances; and these train cars to be provided with suitable tanks, having smooth and impervious inside finish. On streets having railroad tracks, the closet vessels to be carried by hand, or on barrows or hand trucks, and contents transferred to the tanks on the cars; and on streets without tracks, wagon trucks could be used for hauling the tanks from and back to the cars. Arrived at the country destination, the train loads of tanks could be dumped from side tracks on to compost piles, or hauled directly to the fields, as experience should prove most practicable and profitable. A little exercise of ingenuity would contrive means of expeditiously changing the tanks from car to truck and from truck to car again; and the whole operation, except the first collecting, could be performed by mechanical means, even to the cleansing of the tanks preparatory to the following morning's work; and with systematic organization on a scale commensurate with the most extensive requirements. All solid substances, with such a system, could be kept out of the sewers, and nothing but slops and wash-water allowed to enter them from the dwellings; trouble from sewer obstructions would be materially lessened, and but little water for flushing would be required, these being factors of saving in expense. The night work would not compel the payment of a high rate of wages; as compared with cesspool cleaning and the removing of sewer obstructions, it would not be an unpleasant or unhealthy occupation. As an offset to the expenditures, I will refer to the fact that at San Francisco all the stable manure is hauled away, over the hills to the vegetable gardens, from five to ten miles distant. On the Atlantic sea-board it is carried away from the cities on vessels to the farm landings; and it is a very prevalent practice, if not universal, for the farmers to transport all the accumulations of the cities, of this coarse fertilizer, to their lands; and in some countries these accumulations have acquired a value which compels the farmer to pay for them at the stable, in addition to the expense of transportation; and as closet detritus is much richer in fertilizing properties, with systematic, cheap methods of handling, its application would certainly be more profitable. And it is therefore reasonable to suppose that after the system had become established, and the farmers of the neighborhood of a city had become acquainted with its comparative value, they would readily contract to receive the detritus, on delivery, at such prices as would reimburse all of the expense, both of collecting and transportation."

This suggestion is worthy of more than passing notice; let some few leading families inaugurate some such plan, and the masses, sheep-like, will follow suit.

Some years ago we met a shrewd old Irishman, who, commencing poor, had amassed a large fortune, and this is how he did it. He kept a large number of mule teams, which he used to haul cars for the railroads. Whenever a *worked-out* farm was for sale he bought it cheap. He raised all the hay and oats to feed his mules, and whenever he brought a load of hay to his city stables, he returned a load of manure to his country farm. Thus did he appreciate the value of manure, and thus did he increase the value of his cheaply bought farms.

The same principle applied to the removal of human refuse would not only increase our possessions of health, but would likewise materially add to our wealth; for as we have already said, some two millions of dollars' worth of ammonia goes annually to waste in the urine alone of the citizens of Philadelphia.

—The cuca plant from which the new local anæsthetic is obtained, is reported as being planted on a large scale in Ceylon.

Notes and Comments.

Perinephritic Abscess.

There are many abnormal conditions that are calculated to bother the surgeon in arriving at a correct diagnosis, but we imagine that there are few so trying as those cases under consideration.

Dr. Samuel Fenwick writes about them in the *Lancet*, July 25, 1885, and describes two cases that have come under his personal observation, besides drawing some deductions from a large number of collected cases. Severe pain in the loin and abdomen, with some fever, and ultimately the appearance of a tumor, which becames fluctuating, seem to be the most usual symptoms of any importance. Very insignificant evidence is afforded by examination of the urine, indeed so little as to be of no practical value. In some cases the progress of the abscess is very slow, in others rapid. As to prognosis, it would seem that the more acute the affection the better is the chance for recovery. In one of Dr. F.'s cases (a young man aged 21), where the course of the disease was slow, the patient died, and a post-mortem revealed amyloid degeneration of the abdominal viscera, probably due to the prolonged suppuration. The cause is as yet in a chaotic condition. It may be due to disease of the kidney, of the vertebræ or ribs, of the liver, or indeed any cause that will tend to set up an irritation and an inflammation of the cellular tissue surrounding the kidney. The treatment is self-evident. When the tumor fluctuates, aspirate it and give attention to the general condition of the patient. When long-continued and severe pain in the lumbar region is complained of, we may always suspect perinephritic abscess, but we cannot be sure until we have a fluctuating tumor.

Neurotic Pyrexia.

That nervous influences can and do cause pyrexia we all recognize; the method of such causation or the relations between the effect and the portion of the nervous system from which the cause of the effect originates is not of any practical value, hence we pass by his theories, to note the case which Dr. W. Hale White records in one of our recent English exchanges. Since the patient died, and since Dr. H. of course offers no suggestions for treatment, we will note the case very briefly.

A temperate man aged 63, goes to bed at night, apparently well; in the morning he is found insensible. When brought to the hospital, his left side is completely paralyzed—urine normal, temperature 98.7°, pulse 54 full, respirations 27 irregular. The temperature goes steadily up (with but one relapse) until on the morning of the fourth day, it reaches its highest point (105°), and the patient dies. The post-mortem reveals a large hemorrhage in the right corpus striatum, destroying the posterior two-thirds of the caudate and all the lenticular nucleus (except the deep basal part), the external and internal capsule, the claustrum (but not affecting the island of Reil), and the anterior part of the optic thalamus. There was much red softening around the hemorrhage, which completely tore up the brain substance in the affected region, extending as far upwards as the level of the upper surface of the corpus callosum.

The Requirements of a Sick Room and Nursery.

Dr. Roberts concludes his admirable address before the Brit. Med. Ass., by saying:

"If I were asked to enumerate the ingredients and apparatus which are necessary for the cuisine of the sick-room and nursery, I think I could do so very briefly. In addition to the resources of the domestic kitchen and larder, the sick-room kitchen should contain a supply of the following flours: oat, maize, malt, and lentil flours, in a finely pulverized condition and freed from bran. It should be provided with a solution of soda bicarbonate of known strength. This would be of use to add to milk when necessary, and to assist in the preparation of peptonized articles of food. Next to these would come a reliable pancreatic extract, and a preparation of pepsin or rennet for the production of whey. The associated apparatus should include a thermometer wherewith the nurse could, when desirable, heat up cold-made meat infusions to a proper temperature, and regulate the warmth required in the predigestion of food. A double-cased saucepan would form an indispensable item; this makes an admirable hot-water bath for the preparation of beef-tea and fortified gruels. A pair of scales, glass measures, and a mincing machine would complete the list. Finally, there should be, for the service of the nurse, a card or sheet containing plain directions for the preparation of the various kinds of liquid food."

The State of the Urine after Nephrectomy.

At a recent meeting of the Academy of Medicine Dr. Polaillon presented a female patient on whom he had performed successfully the operation of nephrectomy, and gave the following history of

her case. In examining the urine after the operation, it was noticed that this liquid—which was purulent before the ablation of the diseased kidney—became suddenly clear, and was free from pus-globules. The other kidney produced urine having all the normal characters. Three days after the operation it contained 25 grammes of urea; but it must be observed that on that day the patient scarcely passed a litre of urine. In fact, the exact quantity of urine could not be ascertained for the first few days after the operation, as the patient was then in her courses; but as soon as the menstrual period was over, she passed on an average 124 grammes of urine containing 11 grammes of urea to the litre. This small quantity of urea (the normal quantity passed in the twenty-four hours being 25 to 30 grammes) is in relation to the weight of the patient, which was only 35 kilogrammes. In conclusion, Dr. Polaillon remarked that this case is another example of one kidney alone being sufficient for the excretion of the urea contained in the organism.

The Effect of Cocaine upon the Healing of Wounds.

Dr. Lucien Howe concludes an article on this subject in the *N. Y. Med. Jour.*, August 8, with the following propositions:

1. In lesions of the conjunctiva, perfect solutions of the hydrochlorate of cocaine have no appreciable effect, beneficial or otherwise, upon the healing process. When the solution is imperfect, a slight additional hyperæmia is produced, which persists longer than in the other eye, but this is ordinarily of no practical importance.

2. In lesions of the cornea it has a beneficial effect, like other mydriatics, but inferior to that of atropine. In imperfect solutions a perceptible abrasion of the epithelium is produced, and, though this is quickly renewed, the healing is thereby delayed by the cocaine.

3. In wounds of the iris the mydriatic action of cocaine is evident; but here again it is inferior to atropine, and is of little value in detaching firm synechiæ. Imperfect solutions, however, do not appear to hinder the healing process any more than when applied to the conjunctiva or cornea. Indeed, as strong mixtures possess decided antiseptic properties, they would seem to exert a favorable effect in this respect.

Treatment of Venereal Diseases Forty Years Ago.

In the course of his "Address in Surgery" before the British Medical Association, Dr. J. Marshall, when comparing the surgery of forty years ago with that of to-day, when speaking of the progress in the treatment of venereal diseases, said: "Venereal diseases were treated without mercury, or with as small doses as possible, in accordance with views which had then been ably propounded; and, as no distinction was made between the hard and the soft sores, so far as their possible consequences were concerned, whilst the majority of those taken into hospital were evidently soft chancres, followed by bubo, the non-specific or almost non-specific treatment was very successful. Iodide of potassium was becoming a favorite remedy; but it is curious to observe that a common formula in the notes was one grain of blue pill and one grain of iodide of potassium, combined in one mass, to be taken three times a day. When the iodide was administered alone, the usual dose was three grains three times daily; very seldom did it reach to four or five grains. In deep syphilitic ulcerations, and in sloughing gummata, a weak solution of iodine was commonly ordered as a lotion."

Examination of the Yucca Angustifolia.

In a paper on the Chemical Study of Yucca Angustifolia, read by Helen C. De S. Abbott, of Philadelphia, at Ann Arbor, Mich., before the chemical section of the American Association for the Advancement of Science, it was stated that saponin was separated from the leaves and the root of the plant, and that it possesses the property of emulsifying oils and resins. It was also stated that the use of the wood of yucca angustifolia would serve as an emulsifying agent as well, if not better than quillaia saponaria,* since it contains 10.4 per cent. of saponin, while the quillaia contains only 8.82 per cent. of saponin.

The Age of Puberty in Finland.

Dr. G. Heinricus (*Gynakol Centralblatt*, VII., 5) gathered from the journals of the obstetric clinic at Helsingfors the statements as to the first appearance of the menstruation in 3500 women of the lower classes. The average age was 15 years, 9 months, and 25 days. The inhabitants of this country, are six-sevenths Finns and one-seventh Swedes. There was, however, no notable difference as to age in the two races, also no difference in the different parts of the country.

*Tincture of Quillaia as an Emulsifying Agent, by Henry Collier. Year Book of Pharmacy, and Transactions of the British Pharm. Conf., 1879, p. 514.

CORRESPONDENCE.

How to Take a Pill.

EDS. MED. AND SURG. REPORTER:—

If Dr. H. Ashalter and other medical gentlemen would teach people "How NOT to Take a Pill," they, perhaps, would be doing more good for the unfortunates who have to take medicine, than to waste valuable time and space, in a live journal, to tell them "How to Take a Pill," besides preventing more or less torture to the stomach. Medicines in an undiluted form, particularly the drastic kind, unnecessarily irritate the coats of the stomach, and should never be given.

It is a well known fact to well-read physicians that thoroughly diluted medicines in some bland and simple vehicle, are much more kindly received and far more speedily disposed of by the stomach, than in pill form. Properly diluted medicine is not so bad to take if swallowed quickly and followed immediately with a drink of cold water. If you are really sick you will take anything that will do you good, and never "kick" about the taste; and if you are not *actually* sick, and are very sensitive and scrupulous about your taste, what in the world do you want to take medicine for, anyway?

THOS. H. CALLAHAN, M. D.

Buffalo, N. Y., August 19, 1885.

NEWS AND MISCELLANY.

The American Dermatological Association.

The ninth annual meeting was held at the Indian Harbor hotel, Greenwich, Conn., August 26th, 27th, and 28th, 1885.

WEDNESDAY, MORNING SESSION.

The meeting was called to order by the President, Dr. W. A. Hardaway, of St. Louis.

The first paper was read by Dr. J. E. Graham, Toronto, Can. It was entitled

A CASE OF TUBERCULO-ULCERATIVE SYPHILIDE OF HEREDITARY ORIGIN.

The patient was a girl twenty years of age. The skin of the forearm presents elevations and depressions, and in places it is covered with thin scales. For three or four inches above the elbow, the arm is atrophied and covered with cicatricial tissue. At the upper border of the cicatricial tissue, there is an ulcer three-fourths of an inch wide, which encircles the arm. Above this there is sound tissue; no nodules are present. The left clavicle presents, about its middle, a swelling and ulceration about the size of a silver dollar. This was the result of a blow. There is no copper colored appearance. Investigation of the family history showed that the mother was apparently healthy. Three of the patient's sisters, all younger than herself, were healthy. The father died from pneumonia when the patient was eighteen months old. It was subsequently learned that he had also had syphilitic ulceration of the throat.

The treatment consisted in the local application of a mild mercurial ointment and the internal use of bichloride of mercury and iodide of potassium. The condition steadily improved, and in the course of six or eight weeks the ulceration had healed. The patient at that time passed from observation.

The speaker referred to the difficulties of diagnosis in this case, as there was a complete absence of specific history, the facts in regard to the father not being learned for some time after the case had been under treatment. There was no history of any previous evidence of hereditary syphilis, but taking all the facts into consideration, the doctor thought that there could be no doubt as to the correctness of the diagnosis.

Photographs showing the condition were exhibited.

The next paper was entitled

CLINICAL NOTES ON PSORIASIS,

by Dr. F. S. Greenough, New York.

The paper was founded on the records of 394 cases of psoriasis. This number occurred in about 15,000 cases of skin disease examined, and represented about two and one-half per cent. Two hundred and five cases occurred in males, and 188 in females. Several tables of statistics were presented, showing when the cases first came under observation, and the age at which the attack was first observed. In 97 cases the speaker had been able to get reliable evidence in regard to the family history. In 31 cases psoriasis had existed in a near relative, but in 66 cases the patient felt sure that the disease had existed in no other member of the family.

As regards locality affected, where there is much development, it is almost constantly found about the elbows and knees, and more frequently on the extensor surfaces than on the flexor.

Well-marked cases are readily diagnosed, but in some cases there is considerable difficulty in making the diagnosis. It is most frequently confounded with some form of eruption resulting from constitutional syphilis. When psoriasis affects the scalp, its appearance is often similar to that of secondary syphilis. In psoriasis, however, the patch consists simply of epithelial cells, and there is no hyperæmia connected with it. In syphilitic eruption, the crust will contain other elements than epithelial cells, and on removal of the crust, spots of moisture will be detected. A characteristic symptom of psoriasis of the scalp is a band of hyperæmia, about three-fourths of an inch wide, extending around the forehead contiguous to the hair. This is a point of value in the diagnosis betweeen eczema capitis and psoriasis. In the former affection, this band is wanting. In eczema, also, evidences of dried serum or pus will be found. Eczema is apt to extend to the ears. Psoriasis is not accompanied with enlargment of the post-cervical glands, as in eczema. The diagnosis from favus is made by the age of the patient, the evidences of destruction of the hair follicles in favus and the microscopical examination.

On the general integument, syphilides are most apt to resemble psoriasis. The region on which the eruptions appear is important. The syphilides are apt to affect the flexor surfaces, while the psoriasis affects more commonly the extensor aspects. Psoriasis begins as a minute point of hyperæmia, which may last for several days. In

macula syphilide a crop of macules appear within twenty-four or forty-eight hours. When the eruption fades, there is in syphilis a decided pigmentary change. In squamous syphilis the epithelial scales differ from those of psoriasis. In some cases of psoriasis there is severe itching, leading to scratching of the skin, and as a result scabs and crusts make their appearance; but here the cause of the condition is readily recognized.

In regard to treatment, tarry preparations, especially the oil of cade, had been most efficacious. Great comfort may be afforded by the use of emollients. Cod-liver oil is one of the best applications. Chrysarobin is a powerful remedy, but has the disadvantage of destroying the clothing. On the face and scalp, it is apt to produce dermatitis. The internal administration of arsenic in some cases is of benefit. Even after apparent recovery, there is great danger of relapse.

Dr. L. A. Duhring said that the reader of the paper in referring to the diagnosis did not allude to the difficulty sometimes experienced in diagnosing seborrhœa capitis from psoriasis.

Dr. A. R. Robinson said he did not agree with the author in regard to one of his points of diagnosis in favus. In the early stage, you do not find moisture when the crust is removed. There is a shiny appearance. It is only in advanced stages that ulceration is present. While it is true that psoriasis often disappears without producing pigmentation, yet there may be discoloration found on the lower extremities, particularly where there is a varicose condition of the veins.

Dr. R. H. Morrison, Baltimore, had seen many cases of psoriasis, but could only recall one or two cases of psoriasis in the negro.

Dr. G. H. Fox, New York, had been very successful in the treatment of psoriasis and its management. He adopted the teaching of the late Tilbury Fox, who laid stress on the point that in psoriasis, as in other inflammatory affections of the skin, and also in lupus, the first thing to do is to lessen the congestion of the skin; and the speaker did this by restricting the diet, ordering a diet of fruits and vegetables in the summer, and in the winter, give a carefully restricted diet. Tea, coffee, tobacco and stimulants of all kinds are to be cut off. By so doing more will be accomplished than is obtained by using arsenic and local applications at the start.

In regard to local remedies, he never used tar in the treatment of psoriasis. With the application of chrysarosin made at the proper time, there is no necessity for the use of tar.

Dr. C. Heitzman, of New York, said one of the most important points after making the diagnosis is to decide as to the acuteness or chronicity of the affection. If it is acute, local applications are to be avoided. If the case is chronic, chrysarobin may be used with advantage, at least temporarily. It is not a cure. He agrees with Dr. Fox, that restriction of the diet is important for the purpose of lessening the congestion. Tar can not be dispensed with. There is nothing like tar to prevent the recurrence. No mention has been made of pyrogallic acid, which does good in some cases.

Dr. W. A. Hardaway thought that psoriasis is frequently hereditary. The same sort of skin may be transmitted, just as a certain color of the hair or of eye may be transmitted; and then any exciting cause may develop the psoriasis. I have seen psoriasis follow eczema. It is not unlikely that in seborrhœa of the scalp, there may be the development of psoriasis. He had seen the excessive use of oatmeal produce typical psoriasis.

In the treatment of psoriasis it is important to regulate the diet. Cut off meats and aid digestion in all possible ways. As a local application, he believes that chrysarobin with salicylic acid is very useful in chronic cases. This treatment may be followed up by the application of sulphur ointment. In psoriasis of the scalp, sulphur is quite an efficient remedy.

CASES OF ANGIOMA PIGMENTOSUM ET ATROPHICUM,

by Dr. J. C. White, Boston.

Two cases were reported. The first patient was a young man 17 years old, and a Russian pole by birth. Freckles appeared on his face before he was two years of age. These increased in number until the age of six. When the teleniectasic condition first appeared is not noted. When seen, the patient was well developed and apparently in good health. He has, however, grown slowly, and is now no larger than a boy of twelve. The hair of the head is abundant and intensely black. The eyes are also black.

Present condition. Melanosis. The forehead and lower portion of the face are of a dark brown color, and on close inspection small spots of a darker color are seen. The whole trunk is as dark as the skin of a dark Spaniard. The scrotum is very black, and the penis and glans present dark spots. The arms and hands are thickly spattered. The legs are also affected. On the right thigh there is one spot of dark color covered with rather long hair. The mucous membrane of the mouth and pharynx is free from melanosis.

The Atrophic Condition.—On the right side of the face, occupying one-half the surface, is a sharply-defined area of white cicatricial-looking skin. Similar areas are seen on the other cheek, forehead, and about the mouth. A few white spots are seen on other portions of the body. The sensibility of the affected areas is decidedly lessened.

Telengiectasis.—Over parts of the face there are bright red spots, varying in size from a pin's head to a pea. They are most noticeable in the atrophied portions. Within the lids there are two angiomatous new growths. Several vascular twigs are also seen on the face. A few red points are found on the femoral surface.

The second case is a brother of case 1, aged three years, born in New York. When eighteen months old, little colored freckles were noticed on the face. Since then the condition has been developing. His hair is dark brown, and eyes are black. The face is covered with numerous dark brown freckles. The spots are so close together that at a little distance the skin has a uniform color. In some places the spots are slightly elevated. The backs of the hands are covered with dark brown spots. Elsewhere the skin is clear. There are no leucodermic spots, and no angiomatous condition.

From a study of these cases, I conclude that in the beginning the development of these spots can

not be distinguished from ordinary freckles. Gradually the spots multiply, until they involve a considerable portion of the skin. It is probable that several years may advance without further manifestation of the disease. The telengiectasic condition is probably secondary. In the first case it is most developed in the atrophic portion. It is probable that in this case there will be hypertrophy of the epithelium, and final transformation into epithelioma. This has been the result in the 33 cases which have been reported.

Discussion.

Adjournment of morning session.

WEDNESDAY, EVENING SESSION.

RELATIONS OF LUPUS VULGARIS TO TUBERCULOSIS,

By Dr. J. N. Hyde, Chicago.

The following clinical facts were then cited in support of the view that lupus vulgaris was not the result, as had long been taught, of tuberculosis or other systemic diathesis, but was the product of a local infection by bacilli, entirely unassociated with any constitutional evidence of diathesis or predisposition. 1. The unimpeachable character of the family record in by far the larger number of cases of lupus vulgaris. 2. The fact that the disease is in its inception a disorder of the period of childhood, when for the most part, the habits of the child are favorable to infection. 3. The several sites of predilection are those most favorable to such infection. 4. The failure of the disease to spread by inheritance. 5. The remarkable tendency of lupus vulgaris to cutaneous limitation.

THE TREATMENT OF LUPUS BY PARASITICIDES,

By Dr. J. C. White, Boston.

The doctor reviewed briefly the evidence in favor of the parasitic nature of the affection. All previous plans of treatment which had proven most successful were those which would have the effect of destroying any parasite which might be present.

A number of cases were then reported in which the local use of corrosive sublimate in the strength of two grains to the ounce of water or unguent had been used with beneficial results. The ointment was especially recommended. It had been rarely necessary to prolong treatment over two months. As regards the permanency of the cure, the author was unable to speak, as the experiments had been continued for only eighteen months.

Dr. Sherwell expressed his profound disbelief in the parasitic nature of the disease.

Dr. Wigglesworth suggested that the oleates might be more efficient than ointments, on account of their penetrating power.

The next paper was by Dr. W. A. Hardaway, of St. Louis, on

THE TREATMENT OF PORT-WINE MARK BY ELECTROLYSIS.

In the treatment of this affection, the object is to excite sufficient inflammation to cause occlusion of the vessels. Electrolysis seems to be the most convenient way of doing this. At first, the speaker had used a bundle of needles, but he now employed only the single needle. It is important to allow a period of some weeks to elapse between the applications. The histories of three cases were given in which this method had been employed.

DISCUSSION.

Dr. Wigglesworth had seen good results from cutting the vessel in two places and using a preparation of iron, thus closing up the dilated vessels.

REMARKS ON A MOOT POINT IN THE ETIOLOGY OF PSORIASIS,

by Dr. S. Sherwell, Brooklyn.

The speaker had been struck by the great diversity of opinion in regard to the general health of those affected with psoriasis, and in order to arrive at something like a consensus of opinion on the subject, he had referred to the writings of most of the authorities in dermatological matters. Brief extracts from various writers were then given. The evidence thus obtained strengthened the doctor's opinion that the patients with psoriasis were generally in good health.

He thought that the theory of Piffard, who believes that the rheumatic diathesis is a great exciting cause of psoriasis, was the most rational theory that had been advanced.

Adjournment of evening session.

THURSDAY, MORNING SESSION.

At the business meeting officers were elected as follows:

President.—Dr. E. Wigglesworth, Boston, Mass.

Vice-Presidents.—Dr. I. E. Atkinson, Baltimore, Md., and Dr. A. R. Robinson, New York, N. Y.

Secretary.—Dr. G. H. Tilden, Boston, Mass.

Treasurer.—Dr. H. W. Stelwagon, Philadelphia, Pa.

Dr. E. B. Bronson, of New York, was elected to membership.

The next meeting will be held, beginning the last Wednesday of August, 1886, at Indian Harbor Hotel, Greenwich, Conn.

Dr. G. H. Fox gave a brief description of two cases of

DYSIDROSIS.

The first patient, for want of a better term, he classed under this heading. The patient was twenty-nine years of age and had always perspired freely. Four years ago the eruption began on the palms of the hand, and had persisted. The soles of the feet had also been affected at one time. The skin of the hands was decidedly thick and had a dark hue, and was dotted with numerous elevations of epidermis, averaging in size that of a hempseed. The patient had never seen any moisture in connection with this. There had been no itching. The skin never peeled off. Puncture with a needle revealed no serum or fluid of any kind.

The second case was that of a woman, aged 45, a cook, whose general health was good. The present trouble began five years ago. The eruption is on the face, and consists of numerous large and small vesicles containing clear fluid.

MYCOLOGICAL STUDIES IN TINEA FAVOSA AND TINEA TRICHOPHYTINA,

by Dr. A. R. Robinson, New York.

The speaker prefaced his paper with a few general remarks. The epidermis of different individuals differs in susceptibility to these parasites.

Children are more apt to suffer with tinea trichophytina and favus, while adults more frequently presented tinea versicolor. All children are not equally susceptible. In many cases of parasitic disease there is impaired vitality previous to the development of the affection.

The speaker then gave an account of his investigations to determine the exact anatomical seat of the parasitic diseases in question, and to determine the changes which they produced in surrounding tissues. The conclusion was that in favus the rete is not affected until the later stages, when ulceration has made its appearance. The parasite confines itself more particularly to the corneous layer. The parasite of tinea trichophytina in some cases passes down into the rete, while in others it does not.

A number of sections were shown under the microscope, which illustrated the points brought out in the paper.

Discussion.

Dr. White did not agree with the speaker in the importance of depressed general health as a factor in the production of these diseases. He had never seen any necessity for internal treatment in these cases.

Dr. Piffard thought that there is a relation between the condition of the general system and the rapidity of development and rapidity of cure.

Dr. Duhring had always held the view that a particular condition of the epidermis was necessary for the growth of the fungus. The majority of cases of obstinate ringworm, he had seen, have been in individuals in poor health, but there are exceptions to this rule. What this particular condition of the skin is, has not been determined.

ON THE STRUCTURE OF THE DERMA AND THE DEVELOPMENT OF ELASTIC TISSUE IN IT,

by C. Heitzman, New York.

The essayist drew attention to the fact that Professor Stricker, of Vienna, the acknowledged best microscopist of Europe, has now accepted his views concerning the life of Basis-substance. Dr. Gartner, (who was present at the meeting), Stricker's assistant, has brought from Europe an electric picture microscope, by means of which these newly discovered facts can easily be demonstrated to a large audience upon a screen. There are three varieties of basis structure, differing from each other in their chemical constituents, viz., the glue-yielding basis-substance proper, producing the spindles within the bundles of so called fibrous connective tissue; the cement substance between the spindles; and the elastic substance developing along the edge of the bundles in advancing age and in some tumors. All three varieties are traversed by a delicate reticulum of living matter in connection with the protoplasmic cords, that fill the interstices between the bundles in the shape of a comparatively coarse reticulum. Thus it becomes intelligible that in morbid processes, not only the protoplasm, but also the basis-substance, participates in an active manner. After the liquefaction of the solid fields of glue-yielding basis-substance, the bundles directly are transformed into inflammatory corpuscles, from which starts every physiological and pathological new formation.

Dr. W. A. Hardaway described a case of multiple myomata of the skin, accompanied with severe pain.

A. B., age, 36, married, with healthy children, and good family history. Never had syphilis. Present trouble began a year ago. Changes in weather produced pains in the parts which have since become affected. To relieve these, firm pressure was made with the hand. Between the paroxysms, pain was not produced by pressure. Later the lesions presented themselves.

Present Condition.—A strong, hearty man, a peddler by occupation. The pains still persist, recurring at intervals of one night to a week. Each attack lasts two or three minutes, and does not return the same night.

The growth is situated on the right side of the back in the mid-dorsal region, and the course of the growths is obliquely outwards. There are one or two of the elevations on the left side; three of the growths are as large as peas, others are small. The epidermis is not abnormal. On passing the hand over these growths, there is no hyperæsthesia; but on deep pressure in the neighborhood of the larger masses, the patient sinks moaning to the floor.

One of the larger growths was removed, and microscopical examination showed it to be composed of smooth muscular fibre.

From a clinical standpoint, the case bears a close relation to the cases of neuroma which have been reported. The speaker concluded that certain new growths in the skin accompanied with severe pain may be widely different histological structures. We are not justified in assuming that a painful tumor of the skin is a neuroma or fibro-neuroma, simply from its clinical history, without a microscopical examination.

AN UNUSUAL CASE OF TYLOSIS OF THE HANDS,

by Dr. R. S. Morrison, of Baltimore.

The patient was a negro, aged 32; muscular, well-developed, and apparently healthy. By occupation, he was a fireman of a steamer, and had occupied this position for ten years, shoveling coal with the right hand grasping the upper portion of the shovel, and the left hand sliding up and down the handle. Two fingers of the left hand are worn off to the second joint, while the other two are going in the same way, the nails having nearly disappeared. On several occasions he has drawn pieces of bone from the fingers. There has been no pain at all connected with the affection. On this hand there are some large blisters, underneath which there are red granulating surfaces, which are painless. There is no history nor evidence of syphilis. Specific treatment has been used without effect. The man obstinately refused to give up his work, so that little could be done in the way of treatment.

Adjourned.

EVENING SESSION.

THE RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPERTIFORMIS,

by Dr. L. A. Duhring, of Philadelphia.

MYCOSIS FONGOIDE,

by Dr. G. H. Tilden, Boston, Mass.

The speaker described the case of a man, aged 28 years when he came under our observation.

Three years before, several red, desquamating spots had been observed on the elbows. Several months later erythematous spots, accompanied with pruritus, were noted. These lesions retained a dry scaly character. There were no vesicles or pustules. At the end of a year, several red nodules appeared on the face and throat. These, however, disappeared. Later, a small papule appeared on the right thigh, and increased in size. From this there exuded a thin fluid. This was followed by the development in many parts of the body, particularly the axillæ, groins, and neck, of similar lesions, in some cases reaching the size of a hen's egg. After a time there was superficial erosion of some of the tumors, but these excoriated tumors remained firm in consistence. But some of the masses, which were covered with epidermis, were soft, but there was no evidence of the formation of pus. There was also indolent enlargement of the lymphatic glands. The general health continued good. The patient passed from observation, and died at the end of three years and a half.

The report of the microscopist who examined the tumors was read. His opinion was that the growths consisted of the formation of lymph tissue in corium.

Reference was then made to the literature of the subject and the various cases, some 30 in number, which had been reported, were given, and the symptoms and course of the disease were described.

Sections of the growth were also presented for examination.

URETHRAL IRRITATION IN THE MALE AS A CAUSE OF CERTAIN NEUROSES AND OF ACNE,

by Dr. L. H. Denslow, St. Paul, Minn.

He prefaced his remarks by a brief review of the cases of contracted meatus reported by Dr. Otis. He then gave an account of a number of cases coming under his observation in which there were reflex conditions associated with conditions of the urethra, such as contracted meatus, stricture and excessive sensitiveness of the prostatic urethra. In these cases, removal of the urethral trouble produced an alleviation or cure of the affection to which attention had been directed. He also reported four cases in which the same treatment had been followed by marked improvement or cure of the skin disease. In some of the cases ergotin was also employed. The speaker said that he simply reported the cases as so many observed facts, and did not express any theory. He would keep the cases under observation, and at a subsequent meeting give a further report.

Dr. Hyde thought that many of the cases with urethral trouble associated with acne, were patients who probably had been taking for some time balsamic preparations and as a result they had the development of acne.

Dr. Denslow remarked that in all the cases reported, the acne had existed since puberty. The patients were not hypochondriacs, and they were not masturbators. He was satisfied that no drugs had been used by any of them.

Adjourned.

(*To be continued.*)

Psychical Research.

The Philadelphia Branch of the American Society for Psychical Research will resume its meetings next month, and will devote its attention principally to the subjects of thought-transference, hypnotism, and faith cure.

This Branch was organized about six months ago. Dr. Charles K. Mills is the President, and Professor Benjamin Sharp, of the Biological School of the University of Pennsylvania, the Secretary.

The aim of the Society is to approach these various problems without prejudice or prepossession of any kind, and in the same spirit of exact and unimpassioned inquiry which has enabled science to solve so many problems, once not less obscure nor less hotly debated. The founders of this Society fully recognize the exceptional difficulties which surround this branch of research; but they hope that by patient and systematic effort some results of permanent value may be attained.

The following are among the subjects which have been intrusted to special committees:

"1. An examination of the nature and extent of any influence which may be exerted by one mind upon another, apart from any generally recognized mode of perception.

"2. The study of hypnotism, and the forms of so-called mesmeric trance, with its alleged insensibility to pain; clairvoyance, and other allied phenomena.

"3. A critical revision of Reichenbach's researches with certain organizations called 'sensitive,' and an inquiry whether such organizations possess any power of perception beyond a highly exalted sensibility of the recognized sensory organs."

Among the associates of the American Society are the following:—George Biddle, Howard Furness, Professor Horace H. Jayne, H. La Barre Jayne, Louis E. Levy, Dr. Charles K. Mills, Dr. George R. Morehouse, Charles Morris, A. E. Outerbridge, Professor O. Seidensticker, Coleman Sellers, Lloyd P. Smith, and Professor R. E. Thompson.

Vegetarianism.

"I do not hesitate to say," observes Dr. B. W. Richardson, "that this consideration brings us face to face with that system of feeding which is called 'vegetarianism.' We have not to consider how to avoid living on such a purely animal and natural food as milk, for example; we are not to consider how to learn to live on vegetables which contain more water than the 75 per cent. of water which is present in legs of mutton and in other similar animal foods. But we really ought to consider the question of utilizing, on a large scale, all vegetables which, in nutrient value, stand above animal products. We have also to learn, as a first truth, that the oftener we go to the vegetable world for our food the oftener we also go to the first, and, therefore, the cheapest source of supply. The commonly accepted notion that when we eat animal flesh we are eating food at its prime source cannot be too speedily dissipated or too speedily replaced by the knowledge that there is no primitive form of food—albuminous, starchy, osseous—in the animal world itself, and that all the processes of catching an inferior animal, of breeding

it, rearing it, keeping it, killing it, dressing it, and selling it, means no more and no less than entirely additional expenditure throughout for bringing into what we have been taught to consider an acceptable form of food, the veritable food which the animal itself found, without any such preparation, in the vegetable world. With the light of these natural facts filling the national mind, the tendencies of all advanced scholars in thrift should unquestionably be to find out plans for feeding all the community, as far as possible, direct from the lap of earth; to endeavor to discover how the fruits of the earth may be immediately utilized as food; and to impress science into our service, so that she, in her laboratories, may prepare the choicest viands, minus the necessity of making a lower animal the living laboratory for the sake of what is just a little higher than cannibal propensities."

The State Board of Health at Work.

Dr. Lee, Secretary of the State Board of Health, has communicated with the City Board of Philadelphia on a topic which will involve a voluminous report for the purpose of embodying the facts and suggestions in the annual report of the State Board. The interrogatories bear upon the facilities which the health authorities of the city can command at any time in case of an epidemic of small-pox. The questions are:

1st. What are the means at the disposal of your Board for the disinfection of clothing and bedding and upholstered furniture, and carpets which have been used on and about a person ill with any infectious disease.

The reply to that question should contain an account of all buildings and apparatus in use for that purpose, their location, dimensions, capacity, and mode of employment.

2d. Can any citizen avail himself of these facilities free of expense?

3d. What are the modes of conveyance of such infected articles from the house to the disinfecting station?

4th. What precautions are adopted to prevent the spread of infection in transit?

5th. In what manner are the public informed of the existence of these facilities?

Druggists in Convention.

Nearly forty members of the National Retail Druggist Association were present at the opening of the convention at Lafayette Hall, Pittsburgh, September 7. The association now has 3,034 members, an increase of 552 since the last meeting. Among the persons well known to the trade in attendance are George J. Seabury, T. J. MacMahon, H. Atwood, New York; Henry J. Meninger, Coroner of Brooklyn; Charles W. Parsons, representing the *New York Druggists' Circular*, and Hugo Kantrourtz, of the *German-American Druggists' Gazette*, of New York.

Hay Fever Sufferers in Session.

The United States Hay Fever Association, in session at Bethlehem, N. H., elected the following officers: President, Frank B. Fay, Chelsea, Mass.; Secretary and Treasurer, C. C. Dawson, Lowell, Mass.; thirty vice presidents, and an advisory board of thirteen ladies; committee on scientific facts, Professor Samuel R. Lockwood, Freehold, N. Y., chairman, and five others; committee on proposed remedies, M. Richards Muckle, of the Philadelphia *Public Ledger*, and Dr. Edward Townsend, of Philadelphia.

Mixed-up Babies.

A Solomon is wanted to sit in solemn judgment in Milwaukee. Two mothers in a social rhapsody agreed to bathe their baby boys together, and in an evil moment began the diversion. Both boys were but four days old, and neither of the mothers had learned to know her offspring by any distinguishing mark. Somehow the babies got so badly mixed that they never have been sorted since, and the women are crying even yet because each fears she is nursing the other's child. Meanwhile the boys are mum.

Bathers at Public Baths.

The various public bath-houses report the number of bathers for the week ending Saturday September 5th, as follows: Almond street, 516 men, 25 women, 4,118 boys, 199 girls; total, 4,858. Hanover street, 288 men, 14 women, 2,448 boys, 35 girls; total, 2,785. Twelfth and Wharton, 738 men, 14 women, 8,066 boys, 58 girls; total, 8,876. Thirty-second and South, 245 men, 8 women, 4,487 boys, 60 girls; total, 4,800; grand total, 21,319.

Poisoned by Sausages.

Katie Loughlin, two years of age, died in Dover, N. H., September 7th, from eating a piece of sausage declared by a physician to be poisoned. A three-year-old child of James McDonnel was lying for a time at the point of death from the same cause. Thomas Loughlin, uncle of the first-named child, was saved from death by a powerful emetic.

OBITUARY NOTICES.

FRANK B. GALLERY, M. D.

Dr. Frank B. Gallery, one of the most prominent physicians of Rochester, N. Y., died on Aug. 29th, of pyæmia, or blood poisoning, from the effects of an operation performed by him eleven years ago and caught from the patient. He was incapacitated from professional duty some time ago, and removed to the town of Greece, where he died. He was 38 years of age.

ROBERT D. YATES, M. D.

Dr. Robert D. Yates, formerly of Brooklyn, died recently at sea on board the steamer Schiedam, of the Rotterdam Line, of which he was surgeon. He sailed on the steamer for Amsterdam recently. Dr. Yates was born in Brooklyn in 1857, and was graduated from the Medical Department of the University of the City of New York, in 1881. He afterward became an assistant in the Kings County Hospital. At the expiration of his term of service he accepted a position as surgeon of the steamer on which he died. He was on his first voyage when he was seized with malignant typhus fever, and soon succumbed to it. His home was with his parents at No. 360 Bridge St., Brooklyn.

Items.

—A petrified giant "who must have been 12 feet in height when alive," was found near Victoria, B. C., the San Francisco *Examiner* reports, by two farmers who were digging a well. This one may be a distant relative to the Cardiff giant.

—Dr. Ramos, a Brazilian physician, states (*Bull. Gén. de Thérap.*) that refrigeration of the lobe of the ear will stop hiccough, whatever its cause may be. Very slight refrigeration will answer; the application of cold water, or even of saliva, being sufficient.

—The *College and Clinical Record* tells us that Bartholow calls the following a capital application in leucorrhœa:

℞. Iodoformi, ʒj
Acidi tannici, ʒj. M.
Sig.—Pack q. s. about the cervix.

Personal.

—The Chair of Anatomy in the University of Vermont has been offered to Dr. John B. Deaver, Demonstrator of Anatomy in the University of Pennsylvania.

—Assistant Surgeon W. A. Edwards, 3d Regiment, National Guard of Pennsylvania, has been detailed in Special Orders No. 26, Adjutant General's Office, Harrisburg, to act as surgeon of the detachment of the Guard at Creedmoor, on September 11th, and the other days in which the marksmen will take part during the national rifle practice.

QUERIES AND REPLIES.

EDITORS MED. AND SURG. REPORTER:

In your editorial in issue of August 22d, "Possible Mistakes," you do not state whether the post mortem included the brain, nor in what condition it was found. May not the first diagnosis of "meningitis," at the hospital, have been the *correct* one, and the *pneumonia*, the *result* of brain lesion.

The *diagnostic symptoms* of pneumonia were seen after *several days'* illness. The "vomiting, convulsions, general lassitude, headache, grinding of teeth, constipation, later somnolence, gradual transition into coma, besides divergent strabismus and a mild degree of rigidity of muscles of the neck" were present on entering the hospital, and all point to lesion of brain or its meninges. The "weight of testimony" is in the direction of brain difficulty at first, and pneumonia followed because of embarassment of the nerve distributed to the lung.

These symptoms given, I should be loth to accept any other conclusion, unless the post mortem absolutely gave negative evidence of disease of the brain or its meninges, especially at the origin of the *par vagum*.

Many of the above symptoms are common to both pneumonia and meningitis, but the early signs in this case were phenomena of brain lesion, and while the diagnosis of "meningitis" may not have been the exact one, the *developed* pneumonia is partial evidence of difficulty in that section of brain from whence comes the nerve supplying the tissue of the lung. These thoughts are respectfully submitted in the interest of true pathology.

Springfield, Ill. B. M. GRIFFITH, M. S.

Reply.—In reply to the above we wish to say the following: As mentioned in the editorial referred to, the case was reported in a French journal, and we simply translated it. We cannot say, therefore, whether the brain was investigated or not, the original making no mention of the fact.

But in regard to the other remarks of Dr. B. M. Griffith, we must first draw his attention to the fact, that the French writer is an authority on the subject and a physician of vast experience, who could not well be supposed to make such a mistake as the one surmised by Dr. G. Further, a pneumonia, if developing in consequence of a brain-lesion at the origin of the par vagum nerve, is apt to attack one whole lung or both lungs; it certainly does not show the morbid condition, as described in the case quoted. In cases of infectious inflammatory states of the brain or its meninges, if pneumonia set in, an embolus generally causes the pulmonary condition, and the pathological changes induced by such an infarct usually become so rapidly extensive, that whenever pneumonia appears in consequence of an original cerebral lesion, death is apt to occur within from 48 to 72 hours.

While these points and others, which could not be mentioned here without occupying more space than can be allotted for this reply, bring the weight of testimony in favor of the pneumonia having been an original disease in this case, there are some facts which seem directly to prove the correctness of this view. According to the quantity of pneumococci present, the brain in pneumonia evinces all the morbid states from congestion and œdema to inflammation. The picture of the disease usually then is as that presented by the French case, while there never is an initial disease of the brain, in which, when the first symptoms of the complicating lung-affection appear, these are not clearly defined, and in which death would not take place within 3 days. In such cases we do not find the gradual alteration of the complicating malady, but all the symptoms and signs at once rapidly develop themselves and quickly lead to death.

From the symptoms, as reported, from the post mortem examination, and from the facts stated, we can only draw the conclusion that the patient suffered from an infectious pneumonia, in which the complicating morbid conditions of the brain appeared more pronounced during the first and second stages of the lung-disease than the latter itself, but as soon as the height of the latter malady was reached, its symptoms stepped into the foreground; otherwise the lesion of the brain would have ascended to its acme, then all at once become complicated by the pneumonia and produced a fatal issue within 72 hours. In the latter case up to death, notwithstanding the complication and its unmistakable manifestations, the disease always presents the picture of a grave defection of the brain; while as here supposed, after the initial brain-symptoms have commenced the malady, the latter assumes its real character and as such causes death, never again, perhaps, reminding one of the brain-complication at the start, the agony excepted.

We gladly enter upon these discussions, for they show the careful manner in which the articles of the MEDICAL AND SURGICAL REPORTER are read, and they also stimulate all to deeper study.

MARRIAGES.

STOUT—CARTY.—On September 1, 1885, at Daisy Lawn, Florence, N. J., by Rev. W. Williams Christine, assisted by Revs. S. Townsend and John W. Morris, Charles P. Stout, M. D., of Philadelphia, to Miss Kate Carty, daughter of Alfred Carty, esq., of Daisy Lawn, N. J.

DEATHS.

A CASE OF A RARE FORM OF VAGINAL CYST.

BY DAN'L B. D. BEAVER, M. D.,
Of Reading, Pa.

The growth of cysts between the bladder and vagina is of rare occurrence. Of a dozen authors whose books on gynæcology I have examined, only one seems to have observed them. West says he saw one case, and quotes McClintock as having met two. Aside from their infrequency, these cysts are of interest on account of their liability to be mistaken for other diseases, and the ease with which they may be removed when recognized, as was the case in the following instance:

Miss S., æt. 18, of healthy appearance, was brought to me by her mother, about a protrusion between the labia which had been there four years, and had caused some physical and much mental uneasiness.

During this time the growth had been examined by a number of physicians, all of whom said it was a simple prolapse of the vagina. She gave no history of traumatism, nor of previous disease of any of the pelvic organs. Upon examination, there was found protruding from the vagina immediately below the urinary meatus, a soft, elastic tumor of the size of a large pigeon's egg. The vaginal mucous membrane was freely movable upon it, but it seemed adherent to the muscular layer of the vaginal wall, with which it could be reduced easily to a position behind the neck of the bladder. From this position it relapsed immediately upon withdrawal of support, even while the patient was lying on her back.

There was neither pain nor tenderness upon pressure, in the tumor and the parts around it. Although there had not been any disturbance of the functions of the bladder, the proximity of the tumor to that viscus suggested the question of communication between the two.

Withdrawal of the urine did not lessen the size nor resistance of the tumor, nor could the end of the catheter be brought into close contact with its posterior wall.

It did not seem then to have any connection with the interior of the bladder; but yet there might have been a very small opening through which the catheter could not be passed, and which might have been so irregular and winding in its course, as to obstruct the flow of liquid into the bladder. To determine this point with certainty, the cyst was tapped with a very small needle-trocar, and the removed fluid examined for characters which would distinguish it from the excretion of the bladder. This fluid was of a very light straw color, six drachms in amount, with a specific gravity of 1005, and heavily laden with albumen. The specific gravity of the urine was 1015, and it was free from albumen.

It was then clear that there was no connection between the growth and the interior of the bladder.

The cyst having been evacuated, the patient was told to return in two weeks, with the expectation of finding it considerably diminished in size.

September 29. The patient was etherized, and the cyst opened freely through the vagina. It contained about one drachm of liquid, and had shrunken to probably one-half of its former size. After having been opened, the cavity was packed

with a dossil of absorbent cotton, which was previously saturated with tincture of iodine, and this retained in position by a larger cotton tampon in the vagina. The following day another application of iodine was made. Afterward pure carbolic acid was applied once a week until the cavity was entirely obliterated, a period of several months.

June 4, 1884. An examination was made, and both the cyst and prolapse of the vagina found to have disappeared entirely. Since then the lady has been under my observation, but has not complained of a return of the disease.

The causation of these cysts is obscured by the slowness of their development. In this case the disease was known to have existed four years before the discomfort arising from it led the patient to seek advice.

The pathology is equally obscure. Rindfleisch divides cysts into four classes: retention cysts, exudation cysts, extravasation cysts, and softening cysts. The first of these classes embraces such cystic growths as come from closure and dilatation of mucous follicles, or other of the granular structures in and beneath the vaginal mucous membrane. These are comparatively frequent, and after attaining moderate size assume the pear-shape—the mucous polypus. That the tumor in this case did not arise from the granular structure of the vaginal mucous membrane is shown by its deeper attachment, by the free mobility of the vaginal mucous membrane upon it, by its form, and by the fact that it could be pushed easily up to a position behind the neck of the bladder, where it was practically out of the course of the vagina, and where in all probability its growth began and continued until it was driven to the vaginal outlet, the point of least resistance, by the weight of the overlying organs.

Although there is no history of an injury, nor of previously existing disease of the pelvic tissues, it probably arose either from exudation of serum, or an extravasation of blood between the deeper layers of the vaginal wall, or in the connective tissue between it and the bladder. According to Klebs, these cysts may arise from lymph vessels in the connective tissues. Winckel says they may be the result of œdema or hemorrhage into the submucous tissues. Veit thinks they are sometimes the consequence of an abnormal development of the Wolffian bodies of fœtal life.*

The diagnosis of these cysts is sufficiently easy, especially in the absence of inflammatory complications. If it presents any difficulty, it is encountered in determining the presence or absence of close connection with the pelvic organs. When the growth is in front of the vagina, as in this case, it is of course all-important to ascertain whether it is free from the urinary passages before active interference is made.*

The treatment of the disease involves the destruction of the cyst *in situ*, or its removal. The first method to present itself to the mind is the removal of the cyst in whole, as is done with those near the external surfaces of the body; but consideration of the dangers incident to such procedure should lead to the use of milder means. Veit treated one case successfully by laying open the cyst, and stitching its wall to the mucous membrane of the vagina, along the whole line of the incision, thus turning the cyst to account by incorporating it with the wall of the vagina—a very ingenious operation in the case of insufficient vaginal surface. West treated his case by opening the cyst freely, and applying solution of nitrate of silver to its wall until it disappeared.

* Schmidt's Jahrbücher, B. 197, p. 144.

* Hickinbotham reports an interesting case of a vaginal cyst of which the cavity communicated with the urethra. British Medical Journal, April 29, 1882.

AN OPERATION FOR CYSTOCELE.†

BY T. A. REAMY, A. M., M. D.,
Of Cincinnati.

The doctor made a few general remarks in relation to cystocele, discussing its ætiology, and the relief, mechanical and surgical. He considered the methods of Sims, Dieffenbach and Emmet, their benefits and objections, and then went on to the consideration of his own method. He had followed it in public hospitals and private practice for eight years, and had obtained in favorable cases very satisfactory results, and claimed for it some important advantages.

The patient is placed in the extreme lithotomy position, an assistant holding each lower extremity, and the posterior vaginal wall held back by Sims' speculum. The tissues are caught up by small double-toothed tenaculum forceps, and the cutting is done with long scissors, sharp pointed, curved on the flat, the same as used in perineorraphy. A constant stream of water carbolized at 100° F. is allowed to play on the field of denudation. This controls hæmorrhage and keeps the field clear. (The doctor then drew figures on the board explaining the operation.) The denudation is modified in direction, width or length, as each case requires. If it is desirable to cut deeply,

† Abstract of Remarks before the Cincinnati Obstetrical Society.

care must be taken to avoid the lateral branches. There is however no danger of this unless you carry the arms some distance out beyond the cervix. He had never encountered the accident, but theoretically the danger does exist. The lines of denudation should be sharply defined, so that when the sutures are tightened they shoulder against each other and union by first intention is secured. Ordinarily, no cicatricial tissue is found in the line of union. It is quite true, as Thomas has said, that it is not material what direction the denudation may take, provided you get rid of sufficient redundant tissue, and take up the pouch that is present, for it will contract from all directions. You can readily see that the uterus is one fixed point, the meatus another, and the greatest amount of redundant tissue is situated just forward of the cervix.

If you carry the arms of your denudation on either side of the cervix, the direction of the contraction will be directly in harmony with the original construction of the parts, and the contraction, if you get union, will be in the very direction in which you desire to get support. Further, in this method the tissues can be safely subjected to greater traction than they can bear in any other method of procedure. In the clinical use of the method, you will find that you do not have to denude so large a field in order to get contraction, or rather no one path of denudation is so wide. As you approach the urethra you can denude very deeply, but it is not necessary to go so deep there, as it is further up towards the bifurcation of the denudation. If, however, here you simply take off the mucous membrane, and do not go through the muscular tissue of the vagina into the cellular tissue between the vagina and the bladder, the operation will fail, and because you can denude so deeply with safety by this plan, is one of its chief advantages. In two cases in which I desired to cut deep, I have opened the bladder and formed a vesico-vaginal fistula; but I closed it up at once with the sutures of the operation for cystocele, and nothing untoward occurred. Denude deeply, for the more deeply, within limits, the more certain you will be to get good results. As already stated, at the upper extremities of the denudation, it is better not to go too deep on account of the ureters, but that danger, as already stated, I do not regard as great. The doctor usually placed as many as eight sutures to the linear inch of the denudation. The placing of the stitch, which draws the three arms of the Y together, is of importance. Even if the suture should go to the bladder, it will do no harm. It is important to get the border surfaces united perfectly by first intention. The doctor uses the so called silk-worm gut, out of which fish-lines are made. It is really made of the intestines of a fish; it is an animal ligature, and you can with ease render it perfectly aseptic. It is strong enough for any purpose of this sort. You can draw on it with almost your entire strength without breaking it. It is prepared for use by cutting the kinked ends off with the scissors, and throwing the rest into a carbolized solution, (a ten or fifteen per cent. solution in warm water,) and in a half hour it is ready for use. Tie two or three knots, or it may come undone; but you may cut the ends short or long, as you please. Its advantages are smoothness, strength, and if rendered aseptic, is not followed by any more suppuration than a silver wire. It does not become too soft, is not absorbed too soon, but remains like wire for weeks; cut ends will not jag the tissue.

After the operation the patient must be kept in bed, and a self-retaining catheter kept in the bladder constantly for eight or ten days, until union is complete. This I regard as essential, since the distension of the bladder, though it may not prevent union, will nevertheless prevent the union from occurring within the field of the operation in the contracted state so favorable to good results. These remarks will seem to be of more importance if my recommendation is recalled to carry the denudation through the vaginal wall, at least near the centre.

The doctor has operated after the method proposed in fifty cases, and thinks his experience warrants the claim that it possesses the following advantages:

1. Simplicity.

2. Less width of denudation is required at any given point in order to secure the necessary contraction after closure, than in other methods.

3. The deep denudation, necessary to cure in all cases, can be done by this method with greater safety.

4. Since tension upon any one line of the operation after union is less than after other methods, and since the deep denudation causes firm union, the good results are likely to be more permanent.

5. After cure, the vaginal orifice and entire anterior wall of the vagina will conform more perfectly to the original.

—Dr. Maxwell Ramos, in a letter to Dr. Dujardin Beaumetz, speaks highly of cooling the lobe of the ear in obstinate hiccough. It is not necessary to refrigerate; a cold lotion suffices.

PILOCARPINE IN CROUP.

BY JOHN H. OWINGS, M. D.,
Of Deer Lodge, Mont.

December 16, 1883, I was called at 4 p. m. to see Lauretta, age 4 years, daughter of J. McA. On arriving found pulse quickened, hoarse whispering voice, short ringing metallic cough, and stridulous respiration. Upon examination of fauces, found a fibrinous patch on the right tonsil about the size of a large grain of wheat. Respirations 36. Tongue moist, but covered with a yellowish white fur. I learned that she had awakened about 2 a. m. with croupous cough, and that she had had an attack of croup one week before, which had been relieved by vomiting with syrup ipecac and lobelia, but had had no return of the trouble until this a. m. Gave turpeth mineral, gr. 3, and after vomiting freely ordered calomel, ½ gr.; pulv. ipecac, ¼ gr., to be given every hour, with hot fomentations to neck.

9 p. m. Patient much the same. Gave pulv. alum, 1 dr., which was followed by copious vomiting. Hot fomentations and muriate and ipecac continued, promising to call in morning.

7 a. m., 17th. Patient growing worse. Rough hissing or crowing sound both on inspiration and expiration.

Gave turpeth mineral, gr. 5, and ordered tr. verat. viride in ½ drop doses with potassium bromide, gr. 10, every hour, hot fomentations continued, muriate and ipecac discontinued.

11 a. m. No perceptible change.

4 p. m. Stridulous respiration, increasing loss of voice. Gave turpeth mineral, 5 grs., which was followed by scanty emesis. Ordered patient t o be kept enveloped in steam from slacking lime, and to give:

℞. Tr. eucalyptus, ℥v.
Mur. pilocarpine, gr. ½.
Vin. pepsin, ℥j.
Syrup tolut., q.s. ad ℥iv.
Sig.—Give a teaspoonful every half-hour.

9 p. m. Called Dr. M. in consultation, for the purpose of performing tracheotomy. Breathing somewhat easier. Gave 3 grs. turpeth mineral, which was followed by vomiting of a large quantity of mucus with shreds of fibrinous membrane. Ordered treatment continued, promising to return in a few hours.

2 a. m., 18th. Breathing great deal better. During last act of vomiting a large quantity of membrane came away, and is now expectorating a good deal of tough, yellowish fibrin, with frothy sputa.

9 a. m. Crowing cough gone, breathing easy, has been taking beef tea and wine. Ordered eucalyptus and pilocarpin to be given every hour, with generous doses of wine and beef tea.

4 p. m. Patient still improving; breathing natural.

19th, 10 a. m. Patient quite bright; has taken some solid food; cannot speak out loud; has had action of bowels, but urine very scanty. Ordered nitre, juniper, and digitalis, and the eucalyptus and pilocarpin stopped.

21st. Patient convalescent, and visits discontinued.

26th, 2 p. m. Called again to see this little patient, and found a return of disease, with all its horrors. Resumed eucalyptus and pilocarpin, giving it every hour, and directed that three grains turpeth mineral be given every four hours, with lime steam and hot fomentations.

9 p. m. With every act of vomiting shreds of membrane are given off, tinged with blood.

27th, 9 a. m. Patient better. Treatment continued, lengthening the interval between the doses of eucalyptus and pilocarpin to two hours.

28th. Patient still improving. Eucalyptus mixture every four hours, and the diuretic given three times a day.

30th. Patient convalescent.

Since the date of the foregoing case I have had three others, and treated them the same. Two recovered, one died; the latter, some twelve miles from town, I visited twice, and in view of the poor nursing the child received, do not think the treatment had a fair chance.

I have also used the eucalyptus and pilocarpin in fifteen cases of diphtheria, with only two deaths. Tincture iron and quinine, with whisky, were given freely, but I am inclined to think that to eucalyptus and pilocarpin I owe my success in this disease. I have used pilocarpin freely in follicular tonsillitis with the best of results, and mention these facts for the purpose of calling the attention of the profession to them, believing that if properly used, they will not disappoint.

A PECULIAR CASE.*

BY J. L. GEYER, M. D.,
Of Norwich, Ohio.

I present a case, new to me, and as far as my reading goes I am not able to refer to anything similar.

The subject of the present article was a lady aged 52, of nervous temperament. Her figure

*Read before the Muskingum County Medical Society, August 6, 1885.

stooped, shoulders considerably rounded, but not "hunch-back." Married thirteen years, but has never borne children.

For years has suffered from heart disease, that is, more or less palpitation, with constriction of the breast, something after the manner of globus hystericus. Thin in flesh, and slightly anæmic.

Upon examination, I found the tongue furred, color white. Temperature 101°, and pulse 120. The respirations were quick and restrained, caused by the pain on full expansion of the chest; pain more on the left than right side, and beneath the short ribs rather than higher. Bowels costive, which is their natural condition. The lower limbs were painful, muscle and joint alike. No swelling or redness to be seen at any point on them. Chilliness was complained of, and it was followed by headache.

The treatment instituted was palliation: first to relieve the suffering, then to move the bowels, which was not urgently called for at the time; in fact, was delayed until after two days of anodyne treatment. Morphia and quinia were the remedies used at first; the morphia to allay the pain, the quinia as a tonic. This combination could not be continued, as the morphia produced such intense nausea, followed by vomiting. I was well aware of this peculiar idiosyncrasy of the patient; yet, to give it was the better course; to allow the use of the hypodermic syringe required no tedious persuasion. The hypodermic injection consisted of morphia sul., and atropia sul.; this relieved the pain fully.

On the third day a cathartic was administered, and after awhile the pain returned, and with considerable force, but not so great as when first attacked. The drugs consisted of leptand., podophyl., calomel; after their administration all other remedies were discontinued. As the pain continued, a sense of numbness and stiffness began to pervade the extremities—a feeling as if powerless to move the legs, from the hips downwards. A tight or constricted condition of the skin was felt.

Upon trial, the limbs could be moved, and the skin was found in its natural condition—without swelling. A fear of impending paralysis pervaded the mind of the patient. This illusive idea was soon dispelled, and caused a more hopeful spirit.

It was soon observed that the skin on the top of the feet was changing. The skin was thickly marked with white streaks, situated beneath the epidermis, which was more or less transparent.

The light-colored streaks ran in every direction, but more across the foot than any other direction. This phenomenon soon spread upwards, until it reached the umbilical region, where it ceased.

The lines or streaks were about one-sixteenth to one-quarter of an inch wide. The condition presented by the abdomen of a pregnant woman at full time better illustrates the appearance than any other comparison with which I am familiar.

The conditions mentioned commenced on the top of the feet and traveled upwards, but grew thinner and less marked, ceasing in the hypogastric region.

Within two or three days, the lines began to grow dimmer, and in ten days were scarcely visible, finally leaving the flesh with normal appearance.

After the cathartic had produced an evacuation from the bowels, salicylate of soda was administered in small doses, in connection with the use of morphia by the mouth, as upon trial it produced no nausea. As soon as possible the morphine was discontinued, and tinct. iodine, carb. potass., and cit. ferric, with an occasional dose of quinia sulph., were given. The treatment was continued 22 days, with entire relief.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM PEPPER, M. D., LL. D.,
Provost of, and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M. D.

Diabetes Mellitus.

Gentlemen, I shall to-day ask your attention to this patient, A. H., white, aged 46 years, and a farmer by occupation. He has been moderate in all his habits, has had good meals at regular hours, and has masticated his food thoroughly. There is no history of venereal disease. Just before he was taken sick, he had considerable business worry and worked hard. His family history is good. He was apparently healthy and strong when he went into the army in 1861. He then contracted camp-diarrhœa, which has clung to him more or less ever since, the bowels being loose by spells twice a month or oftener. He had no other acute illness, except slight intermittent fever. Four years ago, he noticed that he was drinking a great deal of water and eating ravenously, and at the same time he observed that he was passing too much urine. He soon began to have darting pains in the legs and thighs, and across the loins. In a short time, the pain became so severe as to compel him to give up his

work. These pains gradually diminished, and he has had no pain for the last year. His flesh failed rapidly, and altogether he has lost forty-five pounds. His sight has also progressively failed, and for the last six months it has been so poor that he could not work.

Since he has been in the hospital, (five months) he has had this listless expression. His skin has been harsh and dry with absence of perspiration. The tongue is usually clean, but coated at times with viscid saliva. He has had a great deal of thirst. The digestion for the most part has been good. When he came to the hospital, he was passing from 125 to 160 ounces of urine in the twenty-four hours. On testing it, it was found to be loaded with sugar. There was some irritability of the neck of the bladder, and redness and slight inflammation of the meatus urinarius. From that time until the present his condition has fluctuated, the amount of urine varying from 240 ounces to 100 ounces, varying very much with the diet upon which the man was put; yet not altogether, because the quantity went up to twelve pints while he was on the same diet that brought it down to six pints. His weight has fluctuated between 120 and 125 pounds. He has had numerous boils all over his body.

The eyes have been examined by Dr. Risley, who finds double diabetic cataract, most marked in the left eye.

The spells of looseness of the bowels have continued to recur. Some days ago, it was noted, for the first time, that there was some fever. The maximum temperature was 102°, and was connected with a catarrhal attack, as shown by looseness of the bowels, slight cough, and so on. During this febrile attack, the quantity of urine went down from twelve pints to nine, to six, reaching three pints five days ago. With this there was very rapid loss of flesh, losing nine pounds in as many days. His present weight is one hundred and eight pounds.

During all this time, there has been an abundance of sugar in the urine. The last examination, made a few days ago, gave seven per cent. in a total quantity of eighty ounces. An examination made this morning shows a trace of albumen, and on repeated examination of the sediment, one or two small hyaline tube-casts were found.

Here then, we have a case of diabetes, presenting some interesting clinical features, and it will serve very well as a basis for some general remarks upon this disease. I am wrong, however, in speaking of this as a disease, for diabetes is really only a symptom. It implies the presence of sugar in the urine, and more than a trace of sugar, since there may physiologically exist a minute amount of sugar in the urine, and this may be present more than merely occasionally. There must be a certain degree and continuance of the appearance of sugar in the urine to constitute true diabetes. A mere trace of sugar is consistent with apparent health, and must be regarded as within the limit of physiological variation. A more or less continuous appearance of sugar in notable quantity, constitutes diabetes mellitus, or saccharine diabetes. When it exists as a substantive condition, it is associated with other marked symptoms. The chief of these are a harsh, dry skin, sometimes so marked that sweating can scarcely be produced by severe exertion in hot weather. Secondly, thirst, marked and constant, and sometimes unappeasable. Evidently, there is not only a desire for liquids, but there is also that heated, irritated feeling of the mucous membrane, which craves drink for the momentary local sensation, and in addition there is a craving of the system for larger quantities of liquid. There is also an unnatural desire for food. The appetite is usually strong, and sometimes craving, the desire for food coming back soon after eating, showing that it is not simply a true appetite. Despite the quantity of food taken, there is progressive failure of flesh. In some cases this is very slight, but more commonly there is progressive emaciation. Sometimes this progresses steadily downward, while at other times it is very rapid, with fluctuations. I have seen these patients lose fifteen pounds in ten days, and I have seen them gain flesh very rapidly, but the flesh appears to be of poor quality; it is hard to get and easy to lose. The degree of emaciation in some cases is extreme.

Even more remarkable than the progressive loss of flesh, is the progressive loss of strength and energy. These patients grow weak, and their work tires them. This increases, until extreme debility marks the full development of the disease.

Loss of sexual power is very distinct in diabetes, and is sometimes one of the first symptoms that attracts the attention of the patient. Next, we note the increased frequency of urination, and increased quantity of urine.

You have then these most characteristic symptoms associated with saccharine urine: harsh, dry skin, unnatural thirst, unnatural appetite, progressive failure of flesh, marked loss of strength, loss of sexual desire and power, and increase in the frequency of urination, and increase in the quantity of water passed. Sometimes it will be one or other of these symptoms which the patient first notices, and for which he consults you. If you postpone examination of the urine until the possibility of diabetes is forced upon you by having the patient complain of all this group of symptoms, you will overlook three out of five of the cases coming before you. You will find sugar in the urine very often where the symptoms have not suggested its existence, just as you will find albumen and tube-casts hundreds of times, where the symptoms would not make you suspect the existence of Bright's disease. If you are going to recognize Bright's disease and diabetes early, it will be because you have formed the inflexible rule of examining the urine in every case of disease under your care.

Some of these symptoms require special study. The increase in the frequency of urination may amount to the patient being called up once or twice during the night, and more frequently during the day, or its frequency may be much greater. The quantity of urine discharged varies greatly. It is a common thing to find it running up to 80 ounces or 120 ounces, and it is not rare for it to reach 160 ounces. It may go to 200, or even 240 ounces. This would be regarded as very great, still I have seen twenty pints, and I have seen even forty pints passed in the twenty-four hours. This, of course, is very excessive, but two or three gallons is not rarely met with. I have had pa-

tients who would put a bucket of water on one side of the bed and an empty bucket on the other, and empty the one and fill the other with urine before daylight.

The urine of diabetes presents certain peculiarities. There could not be a better sample of diabetic urine than that which I now show you. It is pale, of an amber color, and has the peculiar odor of new-mown hay, slightly sweetish. Its specific gravity is high, and the degree of elevation depends upon the quantity of sugar and the concentration of the urine. 1025 is a low limit. The specific gravity of saccharine urine is usually above this, but I have seen sugar in the urine with a sp. gr. of 1016. It will not do to exclude the possibility of diabetes because the specific gravity is not above normal. A specific gravity between 1025 and 1045 is very common, but it may go up to 1050 or 1070. It may be very high, although the quantity of water is considerable, the quantity of sugar in such cases being enormous. The total amount of saccharine matter discharged may reach two, three, or even six ounces in the twenty-four hours. Occasionally there will be found that there is albumen in addition to sugar, showing that there is Bright's disease associated with saccharine diabetes. This case presents that serious and interesting complication. I shall not spend time in discussing the various tests for sugar in the urine, but shall simply show you the result of the application of Fehling's test, which is the one most commonly employed. As you see, a single drop of urine produces intense reaction. So much for the clinical symptoms connected with diabetes.

When we come to speak of the causes and nature of diabetes, we find ourselves involved in some most interesting clinical reasoning and physiological speculation. I prefer to limit myself to indicating the clinical conditions under which diabetes makes its appearance. Diabetes has a close connection with the nervous system. It has long been known that in some lower animals, as the frog, an injury to the floor of the fourth ventricle will develop an artificial diabetes, which will soon be followed by diabetic cataract. So, too, we know clinically that if pachymeningitis, a syphilitic gumma, or other tumor involve this portion of the nervous system, the symptom of artificial diabetes will ensue. In some instances, where a traumatic injury in the human subject has involved this part of the nervous system, diabetes has been noticed. It is not only when there is actual injury from traumatism, or the occurrence of some lesion of this part, that diabetes develops, but it is very clear that in many cases a long-continued functional nervous derangement, lies at the root of the production of diabetes. In many of these cases diabetes has followed severe mental depression, or prolonged business anxiety and worry. Depressing passions of any kind may be followed by the occurrence of diabetes. It would seem that it depends upon a derangement of those complicated nervous processes which govern the completion of the digestive act. In order that the starch and saccharine articles of the food shall undergo in the stomach and upper bowel, and subsequently in the liver, those chemical changes which fit them for absorption and use in the tissues—in order, I say, that these changes shall go on from first to last uniformly, regularly, and completely, there is needed a very elaborate nervous control, harmonizing and co ordinating these different stages of the digestive and assimilative acts. It is not to be wondered at that in certain individuals who probably are disposed by heredity to derangements of the liver, stomach, or pancreas, a long-continued profound nervous disturbance, would gradually induce such derangement of the functions of these organs as would show itself by an inability to successfully handle the starchy and saccharine matters, and consequently by the absorption into the blood of incompletely digested substances which will be discharged in the urine. You will see from what I have said, that it is clear that diabetes may also depend upon derangement not of the nervous system, but of some of these organs concerned in the preparation of the starches and sugars; thus, unquestionably, affections of the pancreas, the secretion of which plays so important a part in the transformation of starch and sugar, may be a cause of diabetes. In other cases, disorder of that most complicated function, the function of the liver, will give rise to this condition. It is not impossible that it may depend upon primary derangement of the stomach, but we find this less commonly. Here, then, we have a variety of sources for the production of diabetes, and a corresponding variety in the clinical condition with which it is associated.

Of course, in those whose power to handle and dispose of starchy and saccharine articles of food is limited, diabetes can be produced at will, by giving an unusual quantity of starch or sugar. A certain portion is properly dealt with and utilized, while the remainder passes off in the urine. There are many persons in this condition. There is then diabetes from excessive ingestion of these articles. We recognize a strong individual predisposition to this condition in nearly every case. There are some persons who do not seem to get diabetes under any provocation, while there are others in whom sugar will appear in the urine from very slight causes.

With this variety in the mode of production of diabetes, you will expect to find a corresponding variety in the class of subjects who suffer from this condition. Let me sketch a few illustrations of these classes as they appear in practice. A big, burly fellow came into my office the other day and said, "I came to ask why I cannot sleep with my wife." I told him that probably he had diabetes. Examination of the urine showed it to be full of sugar. He was fat and hearty, and had not lost a pound in weight in a couple of years. You will find one class of cases, generally advanced in years, over fifty, often very stout and burly, with good color, good nutrition, good appetite, who have been particularly hearty livers, eating a great deal of strong, rich food, and often drinking a good deal of beer and wine, who pass a moderate quantity of urine, from 80 to 90 ounces, with rather high specific gravity and containing a moderate quantity of sugar. Many of these patients are disposed to lithæmia, that is to irregular gouty manifestations, and they may even have a distinct expression of gouty symptoms. These individuals will have diabetes for years, without much impairment of general health.

Again, we meet with more severe cases, coming on more commonly in early life, sometimes late in life, of which this patient is a good example, where there is an increased flow of urine, a considerable amount of sugar, and every one of the serious symptoms which have been presented by this man.

Lastly, diabetes is met with in young persons, where sometimes there is a family predisposition, and these cases developed quickly, soon become severe, and run a rapid and fatal course.

The diagnosis of diabetes is so simple as to require no further discussion.

The prognosis is on the whole bad as regards ultimate cure, but not entirely bad, for a certain proportion of cases can be radically cured. The prognosis is, however, usually favorable as regards prolongation of life. The extent of prolongation would be indicated by these conditions: In the first place, the age at which the affection develops. The later in life the better. Secondly, by the way in which the patient holds his weight and strength. If, with a continuance of saccharine urine, the patient keeps his weight and strength, the prognosis is very good, and such cases may last many years; while on the other hand, in proportion as the flesh and strength fail, will the prognosis be unfavorably affected. In the next place, the prognosis will be influenced by the extent to which diet will control the appearance of sugar in the urine. There are some cases, in which a moderate restriction of diet causes a disappearance of the condition. In other cases, where we cut off all the sugar and starch we possibly can, sugar is still elaborated and discharged. Of course, the presence of any local disease, as of the pancreas or of the liver, or still more, such a complication as Bright's disease, would constitute a very unfavorable element in prognosis. Finally, the prognosis would be influenced by the effect of certain treatment upon the symptoms. In intermittent diabetes, that is to say, where saccharine urine is not continuous, the prognosis is always much more favorable.

Now, as to the treatment of diabetes. In the first place, there are some cases which had better be let alone. In elderly persons who are passing a moderate quantity of urine, containing not an excessive amount of sugar, I advise you not to meddle too much with them, nor to try by rigid restriction of diet and the use of powerful remedies to cause a total disappearance of the sugar. For aught you know, the condition may have lasted for years, and the case may be one of those in which there is a discharge of the excess, while the system appropriates as much as it requires. If great changes in the diet are enforced and large doses of powerful drugs given, the nutrition may be so deranged, and the vitality so depressed, that harm rather than good is done. We recognize then, that there are some elderly, gouty, moderate diabetics, in whom the condition should be let alone, save as regards the establishment of very careful hygiene and a moderate restriction of diet. If, after watching the patient for some time, I find that the continuance of saccharine urine is not attended with marked failure in flesh and general strength, I do not worry myself with trying to get rid of the last traces of sugar from the urine.

In general, as you all know, the chief element in the treatment of diabetes is the regulation of the diet. In some cases this must be absolute, in other cases a moderate restriction is sufficient. The fundamental principle is the reduction of the amount of sugar and starch in proportion to the amount of nitrogenous and fatty food. It is commonly best to exclude sugar entirely, or as far as possible, for a diet can be borne with great success which contains no original sugar, as there will be sufficient sugar derived from the transformation of the starchy food. Sugar is particularly irritating to most diabetics. A very little of it will cause an increased flow of urine, increased thirst, and an aggravation of all the other symptoms. In some cases the simple omission of sugar will be followed by great relief.

The starchy food is to be omitted according to our judgment of the severity of the case. When beginning the treatment, it is best to gradually increase it, watching the effect on the urine. It is sometimes necessary to omit starch as far as possible, and let the patient depend almost exclusively upon meats, fish, eggs, butter, cream, succulent vegetables not containing starch, and such beverages as do not contain sugar, combining these so as to make as agreeable a dietary as possible. Often you will be obliged to give a certain amount of starchy food, especially in the form of biscuit and bread. The attempt has been made to furnish a flour containing little or no starch from which biscuit and bread can be baked. There are in the market a large number of preparations under the name of gluten and diabetic flour. Most of these are prepared by washing out the starch with water, and leaving the gluten behind. The flour of almonds, which contains no starch, has been used, but it is not palatable. In many cases a small percentage of starch in these flours does not render them inadmissible in moderate quantity. As you will gather from what I have said, you can frequently allow ordinary white flour, or bran, or oatmeal, in small quantity, if you find that the patient can bear a small amount of sugar in the urine with the enjoyment of fair health. In aggravated cases of diabetes, it is far better to allow a diet which is going to sustain strength and satisfy the appetite than to enforce such a diet as will be repulsive to the patient, and of which he will not take enough to sustain nutrition and vitality. Theory is one thing, and its application in practice is a very different thing. The tact of the physician is shown by steering as close to what is theoretically right as the particular condition of the case will permit. In no instance is this truth more strongly shown than in the arrangement of the diet of the diabetic patient.

At the next lecture, we shall take up the drugs which are most desirable in the treatment of diabetes.

—The driver of a coal cart at Bayonne, N. J., met with a singular accident recently. He was jostled from the wagon by the wheel striking some obstacle. The hind wheel passed over him, crushing his leg, and an instant later the cart capsized and he was buried under the wagon and a ton of coal. He was extricated by some laborers. His injuries are serious. He was taken to the hospital.

EDITORIAL DEPARTMENT.

PERISCOPE.

Some Brief Notes on the Late Outbreak of Cholera in Paris.

Dr. Hy. Tomkins thus writes in the *Lancet*, March 21, 1885:

The outbreak of cholera in Paris during last November afforded an opportunity for those interested in epidemic diseases of seeing and studying this scourge of Eastern countries; and at the end of the month I visited Paris for that purpose, though at that time the outbreak had begun to subside almost as rapidly as it commenced, so that in all I saw only some forty to fifty cases. The history of its appearance and progress in Europe last year may be summed up in a very few words. In the middle of June the first cases were reported in Southern France from Toulon, and the following week cases were occurring in Marseilles, and quickly assumed serious proportions. As it subsided in the south of France it spread to the northern parts of Italy, and early in September, Naples had become attacked with what proved to be a most virulent outbreak, the densely crowded and filthy quarters of that fair city affording congenial soil for the spread of the disease, with the result of a loss of some 11,500 lives. At this time it had disappeared from the towns in the south of France, but towards the end of October cases occurred at Yport, a small fishing village, described as filthy and dirty in the extreme, situate upon the coast of Normandy; then, after a few cases had been heard of in one or two places in Northern France, the startling official notification of its presence in Paris appeared on Nov. 5th, though it would seem that several cases had previously occurred in the capital, but were kept quiet for fear of creating a panic in the public mind. The cases increased rapidly in number daily, and on the 11th of that month 152 new cases were reported, with fifty-six deaths.

The first cases occurred amongst the inhabitants of the east end of Paris, in a dirty, filthy neighborhood off the Faubourg St. Antoine, situated in the eleventh arrondissement, a district lying beyond the Place de Bastille; and to those familiar with this quarter, it will be admitted that for filth and degradation, both morally and physically, it is perhaps worse than anything to be found in the east end slums of London. From the 4th to the 17th, 1250 known cases had occurred, with 617 deaths, and by this time only one of the twenty arrondissements into which Paris is divided was free from cholera. During the last week in November the disease rapidly declined, and in the second week of December it was practically at an end, the cessation having been as sudden as its onset. It is difficult, in the absence in Paris of compulsory notification of infectious diseases, to state with exactitude the total number of attacks, but it was probably not less than 2000, as 900 deaths occurred, and amongst the cases treated in hospital, which were about 1000, there were more than 500 deaths, or a mortality of over 50 per cent.; but the mortality amongst these would certainly be higher than amongst those not treated in hospital. As has happened so often in the past in the history of epidemics, when the cholera reached Paris it was ill-prepared as regards hospital accommodation and general organization for the removal of patients, disinfecting of infected dwellings, and the like. It was at first intended to use only one or two hospitals situate on the north and south of the city; but it was soon found that in face of the sudden and severe collapse, so common in cholera patients, they ran great risk of dying, and actually died, in transit from their homes to hospitals at a distance therefrom, and wards were set apart in the general hospitals situate in various parts of the city; thus, the St. Louis, Tenon, St. Antoine, Lariboisière, Cochin, and other hospitals, all received cholera patients.

At the time of the outbreak the regular ambulance service of Paris consisted of only some half dozen conveyances, which were totally inadequate for the demands made upon them, and ordinary coaches had to be pressed into the service. Immediate steps were, however, taken by the health authorities, and by the time the epidemic was declining an efficient service of forty ambulance carriages was in operation, together with a corps of disinfectors, ready at once to proceed to any house where cholera was reported to be present. In the matter of ambulances we here might with advantage take a lesson from Paris. Instead of being built as ours are of a most pronounced and distinctive, not to say funereal-looking pattern, so that every one at a glance recognizes "the fever van," they are constructed externally to resemble the ordinary coach for hire in the streets, and thus avoid observation to a very large extent. At the Health Exhibition last year there was exhibited an ambulance, built for the London Fever Hospital, which, to all outward appearance, was a handsome brougham carriage of large size, whilst inside it was fitted in every way as comfortably for the patient as could possibly be desired.

All the hospitals in Paris, as is probably well known, are supported out of the rates, and managed and controlled by the governing authorities, there being no hospitals supported by voluntary contributions, and they are under the immediate direction of the Administration de l'Assistance Publique. The routine with regard to cholera cases was as follows: On a cholera case occurring, information was at once taken to the nearest police station, which is in telegraphic communication with the Central Bureau de l'Assistance Publique, situate near the Hotel de Ville; here it was decided to which hospital the case should be sent, instructions telegraphed to the nearest ambulance station for its removal, and some of the staff of disinfectors at once sent to disinfect the patient's rooms.

The hospitals visited by me were the Cochin, the St. Antoine, the St. Louis, and the Mariniers.

At La Salpétrière, though not a hospital in the ordinary sense of the word, several cases occurred amongst the inmates, and Dr. Charcot informed me that the first case they had there was in an old woman who had not been out of the building for four years, and not even a guess could be given as to its origin.

At the Hôpital Cochin, the cholera patients were treated in wooden structures, of which this hospital has many to supplement the accommodation in the ordinary wards. The patients were under the care of Dr. Beaumetz, who courteously afforded me much information and help. In these wards trial was made of saturating the air with ozone. The apparatus employed had previously been in use at Toulon, and consisted of a large air-pump which forced the air through a solution, the composition of which I was not able to ascertain, but which saturated the atmosphere passed through it with ozone, as shown by pieces of paper moistened with iodide of potassium, and starch placed in various parts of the wards being rapidly changed in color and darkened. There was used also in these wards a new remedy, erigeron canadensis, an American drug much lauded for its astringent properties in checking diarrhœa and dysentery. It appeared to check the purging when given, but in many of the cases here purging was very slight, and not the most prominent symptom. The general results of these measures do not appear to have been of a very encouraging nature, as 50 per cent. of the cases proved fatal.

At the Hôpital St. Antoine, situate in the district above alluded to as being the locality where the first cholera cases appeared (and which received the largest number of any single hospital in Paris), transfusion was much practiced by Professor Hayem, who had had made a very simple and easily-managed apparatus for this purpose. The solution used was the ordinary one of common salt with a small proportion of sulphate of soda, and it was had recourse to not only in the worst cases, but also in those of a less severe type, and a considerable number of those thus treated recovered. Usually the injection was made into one of the veins at the bend of the elbow, but in some cases the internal saphenous vein in front of the inner ankle was selected. The immediate effect of that treatment was often for a time most marked and beneficial, appearing to give the patient temporarily new life; but as a general result of the treatment here the mortality also reached 50 per cent. Should I ever have to treat cholera myself, I should certainly be inclined to give transfusion a trial in bad cases, as it without doubt in many instances helps to prolong life, where it does not actually succeed in saving it.

It was at the Hôpital Mariniers, situate near the fortifications to the south-west of Paris, that the most perfect arrangements, from a sanitary point of view, had been put into operation. This was a new hospital, scarcely finished at the time of the outbreak, and was erected for the purpose of an infectious hospital, and presents some interesting features in hospital construction. It has accommodation for 300 patients, and was built in about six weeks. The wards are all one-storied only, and are raised upon wooden piers above the ground, so that the air circulates below as well as above and around them. It was built in a skeleton framework of wood, this being brought to the site ready to put together, and the spaces were then filled in with brickwork, consisting of only one brick in thickness placed end to end, so that the walls are only some four inches thick. Externally they present a neat and substantial appearance. On the inside the walls were finished off with plaster, and had a much more comfortable appearance than the usual temporary wooden erections, and gave none of the difficulties in maintaining an equable and proper temperature met with in these latter. The arrangements for disinfecting everything connected with the wards, etc., was most complete. A large gas stove, on the same principle as the Ransome (Nottingham) disinfecting stove, had been constructed. A special room for fumigating with sulphurous acid fumes was built, and still further machinery was erected of a very simple but apparently efficient character for disinfecting all the waste water, slops, and sewage, before leaving the hospital sewers. At the extremity of the grounds a large tank was constructed in the earth, into which all the hospital sewers opened; adjacent to this was erected a strongly-made iron cylinder and a large steam-boiler. The sewage was drawn into the cylinder and then subjected to a temperature of over 300° by steam forced into it from the boiler before being discharged into the sewers of the town, a temperature probably sufficient to kill all forms of germ life. The working of this was most simple, and necessitated the attendance of only one man, and was in operation day and night. In the wards themselves all infective material—stools, vomit, urine, soiled linen, etc.—were at once treated with chloride of zinc, and this appears to have been the practice followed at most of the other hospitals, chloride of zinc being apparently the disinfectant most in vogue in Paris. For the disinfection of rooms, houses, and conveyances, sulphurous acid was used. The treatment adopted at the Hôpital Mariniers was not of a very special character; opium in the form of paregoric and wine was much used, the limbs rubbed with a turpentine liniment, and hot air baths also given; these two latter remedies appeared to give much relief to the muscular cramps. The mortality here and elsewhere was 50 per cent. The bodies of those who died were covered with sawdust, saturated with chloride of zinc, and buried in a few hours.

As one who saw cholera patients for the first time, what struck me with most force was the great fear which seemed to lay hold of many of these patients, so unlike anything met with in the ordinary zymotics—such as small-pox, typhus, diphtheria, and the like. The sudden and extreme collapse, the comparative absence of real delirium, and as the later stages come on the shrunken features, the shrunken eyeball, dark areola round orbit, and the shrivelled, inelastic condition of the skin, so that when pinched and raised up it showed scarcely any elasticity or tendency to retract itself in the normal manner. In one man at the Hôpital Cochin this inelastic state was marked even in the convalescent stage. After seeing patients in the collapse of cholera, it is easy to understand how it has been possible to mistake patients really alive for dead, so like is

the condition to that of a corpse. After death this shrunken, livid appearance is perhaps as characteristic of the disease as any of the anatomical lesions met with, these latter being quite as vague and indefinite as those of typhus; and in the absence of any ante-mortem history, it would, I think, be difficult to diagnosis a case of cholera from a post-mortem examination alone. There were usually more or less inflammatory changes in the mucous membrane of the intestinal canal, but these varied much in degree; other lesions described were equivocal and doubtful in the cases which came under my notice.

Any remarks upon cholera at the present day without an allusion to the comma bacillus would indeed be the play of "Hamlet" with Hamlet left out; but as a matter of fact, when brought face to face with the treatment and management of the disease. the bacillus has no *locus standi* either as regards treatment or hygienic measures. Whatever may be the ultimate outcome of Koch's discovery, at present it is like the bulk of the work of the physiologist and biologist—interesting chiefly in the laboratory, though none the less great and important results may, and probably will, flow therefrom to practical medicine and treatment of disease. Few of the physicians in Paris (amongst the exceptions notably Dr. Strauss) appeared to trouble themselves much about the bacilli, and in some of the wards but little attempt was made even to find them. Koch describes them as easily found by staining in the ordinary manner; but although I have searched since my return, and have had also the assistance of Dr. Dreschfeld, I have up to the present time not been able to find one, to my mind, respectable comma bacillus in either stools or intestine, though ordinary putrefactive bacilli are to be found in abundance. The further knowledge we have gained respecting cholera from the outbreak in Paris and Europe generally last year has been but little; it did not need this to teach us that filth and overcrowding and insanitary conditions generally formed its special home, or that the poor, the badly-fed, and the intemperate, were its especial victims. In its treatment we have advanced nothing; of its origin, its mode of spreading, its incubation, and its cause, we are as much in the dark as ever. Further evidence has been gained that, given good sanitary surroundings, there is but little risk of direct infection from the sick; amongst the large number of medical men, students, nurses, and other attendants on the sick in Paris, I was not able to ascertain that a single case had occurred.

To those familiar with the cess-pool arrangements in Paris, together with the suspicion as to the purity of some of its water-supply, it will appear highly probable that in the present year we shall have again opportunity of studying all and every one of these questions, even if the disease does not reach our own shores; for spread as it was more or less throughout Paris, there must be myriads of bacilli only waiting for the coming summer and favorable conditions of growth to again break out into activity and life.

—The Orleans family subscribed $10,000 for the cholera patients at Marseilles.

A New Variety of Chronic Nasal Catarrh.

Dr. Harrison Allen thus writes in the *Med. News:*

In a small proportion of sufferers from nasal catarrh, the mucous membrane which lines the nasal chambers is thin, and exhibits scarcely any erectile power. It is abundantly supplied, however, with arterial blood, and everywhere of a uniform light pink color. A highly polished probe placed in the nasal chamber will cause diffuse reflections to appear on the membrane. The nasal septum, as a rule, is without marked nasal deflection, but may be greatly thickened.

The membranes, especially those at the upper portions of the chambers, upon the gentlest manipulation are apt to bleed slightly; the nostrils are not infrequently excoriated, especially in winter. The discharge is mucoid in character when the disease is mildest, but easily becomes turbid upon slight vascular excitement. During the height of an acute attack (which the patient is apt to call "a fresh cold," and which in females is occasionally coincident with the menstrual period), it becomes purulent. The discharge passes into the throat as readily as from the nostrils.

The pharynx is always capacious, the muscular structures active, and the palato-pharyngeal folds well drawn out to the sides. The uvula is always small and sometimes rudimental, presenting the appearance of having been amputated. The mucous membrane is of a pale color, while the larger veins are numerous. At the sides of the pharynx below the tonsils, the peculiar pearly white color characteristic of the alveo-lingual groove, is seen. The tonsils are always small and drawn out to the sides of the pharynx; they are usually not seen, unless the palato glossal fold at first is retracted.

The tongue is clean and the closed glands at the base are few in number, inconspicuous, and permit the longitudinal superficial veins of this portion of the tongue's surface to be unusually well seen. The veins of the mucous membrane of the cheek, which lie on the space between the orifice of the duct of Steno and the reflection from the mucous membrane from the cheek to the alveolar process, are large, superficial, and coarsely reticulated.*

The pale color of the anterior surface of the soft palate extends forward, and is continuous with that of the hard palate without any change. The hard palate itself is exceptionally pale, and the positions of the palatine veins may be determined by bluish streaks on the membrane.

The posterior or palatal portion of the hard palate in the median line is almost invariably marked by a sessile exostosis, ordinarily two-thirds of an inch in length and one-third of an inch in breadth, although sometimes larger. Extending from the anterior border of this exostosis to the position of the rugæ, is a pronounced median ridge, sometimes the seat of a second exostosis, which is marked in the centre by a minute lineal groove. In two cases which I have seen, the palate was highly arched, and a large congenital opening existed in the anterior portion of the nasal septum.

The subjects of this form of catarrh, as far as I

*The buccal veins here described have been neglected by anatomists and clinicians. They are of importance in studying conditions of vascularity in the mouth, nose, and throat.

have observed, very commonly have fair skins, are of spare habit, with a tendency to gray or blue eyes, and light-brown hair. The general circulation is never good; the hands and feet are apt to be cold. There is, very generally, a history of tuberculosis, either in the immediate family, or in the families of the parents, although I have never seen the disease coexist with phthisis.

In examining a case of catarrh of this variety, which had never been subjected to local treatment, the under surface of the narrow middle turbinated bone is often found covered with a thin layer of fibrinous exudation; but in all cases, whether this be present or not, firm pressure of the probe against the ledge-like surface will cause the spot which is pressed upon to become instantly of a bright red color. This is a characteristic sign, and a most valuable one, in determining the presence of the condition described. In attempting to make an examination of the posterior nares, it is often found that, in spite of the liberal diameters of the pharynx, it is very difficult to obtain a view. The difficulty arises from the fact that the powerful levator-palati muscles pull up the soft palate, and persistently narrow or entirely close the opening of communication between the naso-pharynx and the oro-pharynx.

This form of catarrh may be easily distinguished from that of any other variety; for, so far as I know, the group of signs and symptoms above given under no other circumstances co-exist. In catarrhs accompanied with inflammatory extravasations or œdema, the pharynx is of a dusky-red color, and the anterior border of the reddened soft palate is sharply limited from the paler hard palate.

The exceedingly sensitive character of the nasal mucous membrane, and its disposition to slight bleeding from trifling causes, the absence of the erectile tissue, or its rudimental character when present, a nearly straight septum (hence the absence of nasal obstruction),* form a group of characters which may be easily recognized.

This form of the disease is not common. I have had the opportunity of carefully studying twenty cases.

The prognosis for cure is unfavorable. In seventeen cases, very marked alleviation followed treatment, while in three no benefit followed the most carefully devised and systematic treatment. I have reason to believe that in these three cases, the failure could be largely attributed to hereditary peculiarities, the results of tubercular history. In one case three grandparents and a maternal aunt had died of consumption. In another, all members of the family had had "weak throats," a maternal aunt and uncle and a paternal aunt dying of phthisis. The third case was complicated with neurasthenia. The remaining cases were greatly benefited by applications of a saturated solution of nitrate of silver over the more hyperæmic portions of the mucous membrane. This agent, when used with care on a surface not larger than a duck-shot at a single sitting, is readily borne, and is often followed by the most satisfactory results. I am in the habit of first covering the middle surface of the turbinated bone with these applications, and repeating them every other day. The galvano-cautery under no circumstances is to be used. It is in this class of catarrhal cases that I have found the oleo-resin of cubebs of advantage; indeed, in my experience it is the only form of catarrh in which that preparation is of any use. The agent can be lightly painted along the sides of the chamber, care being taken that it does not trickle into the pharynx. Minute doses of arsenious acid in conjunction with cod-liver oil and oleo-resin of cubebs, are well borne, particularly in the winter months.

This form of catarrh is closely allied to ozæna. I remain under the impression that the distinction between the disease and ozæna remains one of grade, rather than one of distinction in kind. While I have never seen ozæna associated with the disease, the characters of ozæna appear to be a high grade of inflammatory state, associated with a disposition to fibrinous exudation, engrafted upon the general features of the phase of nasal and pharyngeal distress as here described.

*A sense of obstruction is sometimes referred to the plane of the middle turbinated bones, or obstruction to breathing may be reported as occurring during the night, especially during sleep. In the main, the statement is correct that the turgescence of the mucous membrane is insufficient to close the nose.

"Indigestion," and its Treatment.

A writer in the *London Medical Times* (July 4, 1885,) says:

There is no complaint of which the diagnosis and the treatment are more often vitiated by gratuitous theorizing, and consequently meddlesome drugging, than chronic indigestion. Moreover, this same love of theory and "treatment"—a curious source of ready satisfaction to many medical minds—leads to a great exaggeration of the number of cases which are dubbed dyspeptic. Satisfied with a supposition of some derangement of the secretions or movements of the stomach which cannot be proved or observed, but is all the more elaborately and dogmatically enunciated, too many of us are apt to search no further than this organ for the ultimate cause of the complaint which we have to treat. And yet it may be boldly stated that an immense majority of the patients who come to doctors for relief from pain, or discomfort of some kind, be it "fullness," or flatulence, or flushing, after taking their meals, have little or nothing the matter primarily with their stomachs, and do not require, but should rather avoid, any medicine directed thereto, or indeed any drug at all. This proposition will be found to be true just in proportion to the *apparent* freedom of these patients from any ailment except that of the stomach. In considering this question, cases of organic disease, as cancer, or ulcer, or gastric catarrh from obvious irritatives, such as alcohol, or patently immoderate living, are left out of sight; for they are evidenced by other symptoms beyond those to which we refer, and, generally revealing themselves to the careful medical enquirer, are not ticketed as dyspepsia. Equally of course are ignored the common derangements of the stomach which would more properly be termed acute, occurring in the course of fevers and inflammations, or as the immediate results of acts of gluttony or drunkenness. The *ordinary* dyspeptic patient is one who suffers at certain times after taking food; and even if never quite

free from his complaint, which is not often the case, is at all events much worse at such times than at others. Many, indeed, both claim and appear to be quite well except at the fatal after-dinner time.

To come to a correct conclusion as to the diagnosis and treatment of these cases, a comprehensive knowledge is brought into requisition, and the more such knowledge is practically applied, the smaller will be the number of patients who will be vaguely called dyspeptics. We shall then eliminate the gouty, and the sufferers from the less obvious forms of renal disease, and what is often lost sight of, the victims of unsuspected cardiac mischief. It is not altogether rare to find patients persistently treated, and treated in vain, for "dyspepsia" by so-called stomachic remedies, be they acids, or alkalies, or bismuth, or the many artificial and almost useless so called physiological "digestives" the names of which end in *-pepsin*, whose symptoms, though incidentally referable to gastric congestion, are really due to disease of the heart, and especially of the mitral valve. Again, the sufferers from chronic pulmonary affections, and notably from bronchitis, furnish a considerable contingent of cases which for the patients' sakes should not be put down as "indigestion." The host of neurotics, whose prominent complaint is dyspepsia, will certainly be more successfully treated by general hygienic or "tonic" methods than by "stomachic" medicines, or indeed, very often, than by giving much attention to even dietetic rules; and a change of habits or social surroundings will frequently succeed where all the resources of the cook and the druggist have been taxed in vain by the "therapeutical" physician. Psychical dyspeptics are misunderstood and maltreated by thousands.

It would seem perhaps scarcely necessary to insist upon the all-important part played in the production of some of the most troublesome cases of indigestion by the deficiency or absence of teeth. But this cause is surprisingly often overlooked by the most ardent treaters of disease, and cases might be quoted in numbers where many doctors, including those the most eminent "for the stomach," have vainly drugged for years a healthy organ, whose owner has been at last relieved of his intolerable sufferings by the art of the dental mechanician.

Most prominent of all perhaps among the dyspeptics who apply for relief are those whose sufferings, sometimes of great severity, are due only to neglect of proper intervals between their feeding-times. Not quality or quantity of food is here at fault at all. These are they who take good breakfasts, because their digestive organs have had their physiological and therefore unstarved rest; who do not suffer much or at all after luncheon (if they take any); but from an over-late dinner, when their possibly idiosyncratic stomachs have been long empty, undergo tortures which only an unnatural appetite can drive them to endure. Drugs are not good for such as these.

From this small and imperfect selection of common-place sketches from life it will be seen that "dyspepsia" ought not to be so great a bugbear to the doctor as it often appears to be. The despair of the therapeutist should decrease with his dwindling drug-list. Useful as in very many cases of organic disease of the stomach various medicines are, and indeed indispensable as perhaps the only means of relieving the patient, they are in such cases only palliative; and the same, in a modified sense, may be said of most of the remedies in the forms of acids and alkalies which are given at certain times and with certain rules, with the often plausible notion of affecting the secretions of the stomach. A dose of such medicine may relieve the pain or discomfort which follows a meal, or may even, though more doubtfully, prevent such pain in rare cases by promoting digestion; but the effect is only temporary; the cause is not touched, and the theory which prompts their administration is elaborated more in the study than at the bedside. The stomach rarely suffers alone; never, perhaps, in indigestion which is *curable*. In curable dyspepsia drugs reach their lowest, in incurable disease of the stomach their highest, point of utility. Pepsin may relieve discomfort for the moment; but it seldom does, and at best it is a sorry therapeutic crutch. Opium, and even bismuth, are often a god-send to a cancerous stomach. And with respect to the purely dietetic treatment of dyspepsia, there are two sides to the question. Doubtless the dyspeptic should not disobey the accepted dicta of physiology and of general experience with regard to his manner of living; and broad rules should in most cases be enforced. But in proportion as a man is dyspeptic, so he often finds out best for himself what to take and what to avoid; and as long as his meals are moderate in quantity and regular in time, he will often be better with a comparatively unrestricted diet-table. The most "dietetic" of doctors rarely practice themselves what they preach to the healthy, and the least dyspeptic of dyspeptics are verily not those who are always taking thought for their daily meat and drink.

A Case of Hemorrhagic Measles, Complicated with Broncho-Pneumonia, Supra-Orbital Abscess, Purulent Ophthalmia, Perforation of the Cornea, Metastatic Abscesses, and Spontaneous Gangrene. Death.

Dr. L. A. Malone reports the following case in the *Archives of Pediatrics*, January 15, 1885:

James Kelly, aged two and one-half years, was admitted to the Asylum Hospital, October 21, with incipient measles. His general condition at that time was poor, nutrition defective, and family history bad, the mother insane and the father weak and strumous. The case was furthermore complicated by a contusion of the right eyelid, which, at time of admission, was not apparently of a serious character, but proved eventually an important factor toward a fatal termination.

October 8th.—The boy is found in a critical condition, with a temperature of 102°, pulse 136, and respiration 60. Very drowsy.

R.	Ammonii carb.,	gr.xv.
	Tinct. nucis vom.,	min.viii.
	Tinct. digitalis,	min.xxx.
	Aquæ camphor,	
	Syr. tolut. b.,	āā ℥j.

M. Sig.—Teaspoonful every hour. Poultices to chest.

9th.—Pulse 110° and respiration 44; breathing

easier, but patient very drowsy; base of left lung consolidated and right eye suppurating.

11th.—Measles fading out, boy still very dull, cough infrequent.

13th.—Temperature 100°, pulse 134, respiration 56. The eruption had begun to decline and purpuric spots to occupy the site of the eruption. ℞—Quinine, gr. ij, t. i. d. and forced feeding. There was considerable discharge from an opening above the tarsal cartilage of right eyelid. On probing this pus cavity it was found to extend deep in the orbit. The general condition of the patient on this day was wretched; the character of the respiration was labored; collapse of the base of right lung, and very limited expansion of the thoracic walls; large mucous râles were heard over the whole chest; at various intervals points of inflammation, involving the subcutaneous areolar tissue began to appear; treatment continued, with milk and whisky *ad lib.*

14th.—Not so stupid, and occasionally asks for food.

15th.—Temperature 99.8°, pulse 92, respiration 56. The respiration was still labored and superficial; loose mucous râles heard over whole thorax; sordes on lips and teeth; large purpuric blotch on the right buttock, with threatened abscess; free discharge from the right eye; desquamating very freely; small sloughs on forehead and upper extremities—these sloughs extending no deeper than the subcutaneous areolar tissue, and ranging in size from a split pea to a dime.

16th.—No worse, if anything the general condition improved; cough more infrequent; cornea of right eye opaque, but less discharge from the eye and nose.

17th.—Temperature 99.6°, pulse 128, respiration 56. Respiration labored; no mucous râles, but bronchial breathing on both surfaces of both lungs; new inflammatory points, and new sloughs on face and upper extremities; fluctuation felt over right buttock, but limited in area to about one square inch; still desquamating freely, with pronounced mouse-nest odor.

18th.—No worse, but cornea opaque. ℞—Murdock's food.

19th—5 p. m.—Temperature 103.5°, pulse 140, respiration 60. This was the only visit in the afternoon of which record was made. Respiration irregular and labored; breathing bronchial; but little discharge from the eye; skin hot and dry; thirst intense; very restless; desquamation as freely as before; odor of person offensive.

20th.—Temperature 100°, pulse 122, respiration 56. Pulse better than the day previous; sub-crepitant râles heard on posterior lobe of the left lung; little discharge from the eye; sleeping well, but restless when disturbed.

21st.—Temperature 100°, pulse 128, respiration 60, jerky and labored. Large mucous râles heard at the end of inspiration; new sloughs on the face, arms and hands; cornea of right eye protruding, and discharge very copious; restless, and thirst intolerable.

22d.—Temperature 100°, pulse 128, respiration 60, and still jerky. Large mucous râles over the whole thorax; during the night previous, patient had a severe attack of dyspnœa; thirst great; opening in right upper eyelid had scabbed over; an increase in the number of sloughs on face and extremities; the epidermis over the right buttock had sloughed off to the extent of the purpuric patch mentioned above; this denuded surface was extremely sensitive, as the papillæ of the chorion were exposed; patient's general appearance much worse.

23d.—Temperature 99.2°, pulse 130, respiration 48. Patient very stupid again; sub-crepitant râles were now heard in place of mucous bubbling on the day previous; flattening of the right side of the chest more marked; breathing very labored and irregular. Tinct. quebracho added to expectorant.

24th.—Temperature 101.4°, pulse 134, respiration 42, and jerky. Had a severe attack of dyspnœa, lasting four or five hours.

25th.—Temperature 101°, pulse 140, respiration 56. Breathing very much labored; large, loose, mucous râles over both lungs, and a very troublesome and persistent cough; evidently failing.

26th.—Temperature 101.5°, pulse 140, respiration 46. Flattening of right lower portion of the thorax, indicating complete collapse of the lung; patient did not seem so stupid this morning; pulse good, but in general seemed weaker; during the remainder of the day the patient gradually failed, dying at 6 o'clock a. m., October 27, without apparent pain. No post-mortem was allowed by the father.

Remarks.—This case is chiefly noteworthy from the number of complications observed and the extent of the superficial gangrene. Hemorrhagic measles, associated with pneumonia, usually runs a much more rapidly fatal course than that of the present case, which might have survived the pulmonary complication had it not been for the injury previously inflicted upon the eye. This, though it seemed at first trivial, was the foundation for a supra-orbital abscess, which discharged profusely and was undoubtedly the cause of purulent absorption, the metastatic abscesses, and death. The etiology of the gangrene of the buttock is not so clear, though Eustace Smith states that a special disposition thereto is occasionally observed after measles. In this case it was directly consequent to an immense purpuric patch occupying almost the entire right buttock. Elsewhere the purpuric patches faded into brownish stains, but here the discolored integument became first dark blue, and then almost black. At one time it was thought fluctuations could be detected beneath this hardened, parchment-like cuticle, but an exploring-needle failed to demonstrate its presence. At no time was there any increase in the size of the original gangrenous spot, though a smaller one later appeared on the opposite side. Superficial sloughing took place on the seventh day, leaving a raw, exceedingly sensitive surface, which showed no effort toward repair. Dusting with equal parts of iodoform and bismuth subnitrate promptly relieved the pain, but death intervened too soon to learn whether this treatment would have been effectual for recovery.

—Christian Cooper, of the town of Livingston, Columbia county, died recently, aged 111 years, 10 months, and 15 days. Mr. Cooper was active, and retained his mental faculties until a few days before his death.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——An interesting series of statistics of one hundred cases of urethral stricture treated by electrolysis without relapse, are published by Dr. Robert Newman, Surgeon of the North Western Dispensary, New York city.

——Dr. Henry Leffmann, of this city, in a recent reprint, urges the medical use of pure alcohol and alcholic mixtures of known composition in preference to ordinary fermented liquids. His reasoning is cogent.

——The same writer sends a paper on "Medical Education," reprinted from the Proceedings of the Philadelphia County Medical Society.

——The "Report of the Proceedings of the Tennessee State Board of Health," at its meeting July 7, 1885, forms a pamphlet of 24 pages, and contains a variety of matters of local interest.

——Dr. A. B. Cook, of Louisville, describes, in a recent paper, a case of complete laceration of the perineum and part of the recto-vaginal septum. Erysipelas followed, but by careful treatment the patient was ultimately discharged cured.

——A long and careful compilation on "Health Statistics of Women College Graduates," by Annie G. Howes, shows that the female graduates of our colleges and universities do not seem to show, as the result of their college studies and duties, any marked difference in general health from the average health likely to be reported by an equal number of women engaged in other kinds of work, or, in fact, of women generally without regard to occupation followed. Copies of this pamphlet may be obtained of Miss Marion Talbot, 66 Marlborough street, Boston, Mass. Price, 25 cents.

——The medical uses of cocaine in hay fever are described by Dr. Roberts Bartholow, of this city, in a paper before us, issued by Messrs. John Wyeth & Bro., and the various applications of the drug in practice are reviewed by a competent hand in a neat pamphlet, distributed without charge by Messrs. Wm. R. Warner & Co., also of Philadelphia.

BOOK NOTICES.

A Complete Pronouncing Medical Dictionary, Embracing the Terminology of Medicine and the Kindred Sciences, with their Signification, Etymology, and Pronunciation. By Joseph Thomas, M. D., LL. D., etc. 1 vol., large 8vo., pp. 884. Philadelphia: J. B. Lippincott Company. 1885.

There has been real need of a work of this kind, and after a careful examination of the manner in which the author has performed his laborious task, we have no hesitation in saying that he has succeeded in presenting a medical dictionary, which for the daily use of the student or the practitioner is superior to any other in the language. He is especially careful in assigning the derivation of the words, their accents and pronunciation, and their exact meaning according to the usage of the best modern writers. In the preface he explains how extremely difficult at times this is, owing to the absence of any recognized standard of Latin pronunciation or of English spelling; and every editor and lecturer will be prepared to appreciate what he says on these points. Through the assistance of specialists in various branches of medicine and pharmacy, he has been able to add all the recent introductions to the phraseology and nomenclature of medicine, surgery, pharmacy, chemistry, and the allied sciences, and in this respect the work stands a long way ahead of any that has yet been issued.

The typographical display of the words and their definitions is exceedingly judicious, and the paper and sizes of type leave nothing to be desired on these heads.

An appendix is added to the volume, giving the most essential elements of Latin grammar, the most usual Latin terms found in medical writings, abbreviations employed, scales of weights and measures, doses of medicines, etc. These are conveniently and clearly arranged, and enhance the value of the volume.

Poisons, their Effects and Detection. A Manual for the Use of Analytical Chemists and Experts. By Alexander Wynter Blyth, M. R. C. S., etc. Vol. II.

On Renal and Urinary Affections. By W. Howship Dickinson, M. D., etc. William Wood & Co., New York. 1885.

These two volumes are the July and August issues of "Wood's Library of Standard Medical Authors," and are valuable additions to the series. We have previously spoken of the treatise of Mr. Blyth; that of Dr. Dickinson treats of a number of miscellaneous affections of the kidneys and urine, such as are most frequently met with. It does not pretend to be a complete essay on the subject, but will be found a valuable compend of information on many obscure points of pathology and treatment.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

AID TO BE OBTAINED FROM GERMANY TO CONTINUE AN AMERICAN LITERARY WORK OF GREAT VALUE.

We translate in the following a communication, which was published by Prof. Ernst v. Fleischl, of the Vienna Physiological Institute, May 16, of this year, in the well-known German medical paper, *Centrlbl. f. d. Medic. Wissenschaften.*

We, as Americans, would be ashamed that what we are indirectly reproached for in the learned Professor's letter, is possible in our country, were it not for one fact: that very few physicians on this side of the Atlantic are acquainted with the great work of Dr. Billings. Some years since, we remember that circulars were sent around informing the medical profession in this country of the scope of the work; but most physicians scarcely looked at the circular, surmising the publication to refer to the medical literary work of our government. We feel convinced, should Dr. Billings' praiseworthy work be well advertised amongst medical men, that a sufficient number of subscribers will soon be secured to guarantee the success of the invaluable undertaking.

The original, translated, reads as follows:

"A LITERARY DUTY OF HONOR.

"*Admonition to all German Colleagues.*

"The whole world of medical scientists, and before all the German medical investigators, are about to commit the wrong of an omission scarcely credible and very far-reaching, and to throw a doubtful light on the intensity and the sincerity of their literary necessities and interests.

"As I am persuaded that the dishonor which threatens to befall us in fact is not merited, but is to be referred to an ignorance, though not less reproachable, I beg permission of the editors of this paper to address a few explanatory words to the large circle of its numerous readers.

"1880 two medical literary undertakings of truly incalculable value have seen the light of the world.

"One is independent of extraneous aid, a magnificent monument of honor, worthy of highest admiration—a present of the American nation to the scientists and physicians of all countries. Beneath the modest title of a Catalogue of the Medical Library of the War Department in Washington, there is really concealed a complete literary index of all ages and nations, containing all books, monographs, journalistic articles, ever published

on any subject in the least connected with medicine, arranged according to the name of the subject, and also containing the writings of every author, classified according to the name of the author, and whereby the names of the theses and of the authors are promiscuously arranged in alphabetic order. The whole work, composed by a bureau of twelve to twenty co-laborers who, under the direction of Dr. Billings, have been busy with it for more than twelve years, will probably fill from eighteen to twenty-two volumes (in quarto), of which five have thus far appeared, each of more than 1,000 pages. The enumeration of the names of the journals, archives, and other periodical papers, which have been consulted in this grand work, fills alone 126 narrowly-printed quarto pages.

"This invaluable work is not for sale, but is presented to all public libraries by the American government. It is also presented to a few scientists and physicians known to the American government, and to medical libraries, and probably no library would apply in vain in Washington for a copy.

"The second enterprise has been started by the same industrious (*arbeitsfrohen*—verbatim, glad of work) Billings, who is the real creator and chief co-laborer of the first.

"This second enterprise has the title 'Index Medicus,' and is arranged exactly like the large catalogue, and really a continuation of it, beginning at the conclusion of each single volume; but certainly at the same time an absolutely complete index of modern medical literature. Twelve monthly numbers are yearly published, with a thirteenth index No., and its contents are so up to the time, that all publications are mentioned up to within two months of the appearance of each volume. All theoretical branches are naturally treated with the same completeness as practical ones.

"With the last No. of 1884, the news was published that the 'Index Medicus' would cease its appearance with that No., viz., on account of want of subscribers. Hoping for a large number of subscribers, the price originally demanded was $3 per year, but it had later to be raised, first to $6, and finally to $10 annually.

"Actually scared by the news of the cessation of this really indispensable literary aid, I inquired by letter of Dr. Billings, with whom I am personally acquainted, for a more detailed explanation, and from his reply I discover the following shameful facts:

"Both editors, Dr. Billings and Dr. Fletcher, have always done the enormous labor which the 'Index Medicus' demands, completely without compensation—totally gratuitously. Notwithstanding all this, the publisher who has thus far published the work, has lost each year never less than $1,000 by this undertaking!! And the simple reason of this is: the 'Index Medicus' has in France 6 subscribers, in Austria 7, in Germany 9, in Italy 6, in England 34, and in the United States 320!! Dr Billings is of the opinion that there are in the whole world not 500 human beings who would really feel the necessity for such a work! That cannot be possible!

"Partly induced to do so by my urgent representations, and by my promise to work with all my power for the success and the distribution of the 'Index Medicus,' the never-tiring Billings—the former publisher having died—has obtained a new publisher willing to continue the work, and this year, therefore, the 'Index' will again appear, first for the (comparatively by no means large) price of $10; but should the enterprise give but a little proof of success, for a much smaller annual sum."

Prof. v. Fleischl then advises the German medical profession to subscribe for the work, etc., and concludes:

"What induces me thus personally to interest myself, and to publish this 'admonition' (Mahnruf), is exclusively the conviction that we have to look upon it as an affair of honor, that an undertaking of such utility and disinterestedness should not fail for want of subscribers (verbatim: participation, interest).

(Signed) "Prof. Ernst v. Fleischl,
"Physiolog Institut, Währinger Str. 11.
"*Vienna, April* 28, 1885."

Should this translation, read as it will be by the thousands of readers of this journal, not cause at least a few of them "to go and do likewise?"

THE PROPHYLAXIS OF CHOLERA.

Bearing in mind that the last epidemic of cholera in this country commenced in December, it is well that we should know all that is to be known in reference to prophylaxis; for having been unvisited during the summer is not proof that we are not daily in danger, so long as the disease has a home in countries so directly connected by commerce with our shores as are France and Spain.

We are all familiar with the means usually

recommended as prophylactic against cholera, but in the course of Dr. Pringle's address before the British Medical Association, we find some new points not hitherto recorded. Without entering into the merits of his arguments, we will state some of his valuable conclusions, premising that his utterances are the results of cholera experiences during a service of thirty years in India.

First in order of importance, as affects the commerce of a nation, is quarantine.

Dr. Pringle has satisfied himself that the period of incubation of cholera is forty-eight hours; hence when a vessel arrives from an infected port with cases of cholera on board, he would remove all patients capable of being removed to a hospital ship moored in a secluded locality, with special reference to the prevailing wind, while suspicious cases should be kept under observation. As regards the remainder of the passengers and crew, they should be removed to a quarantine ship, and if no case of cholera appears among them for forty-eight hours, they should be permitted to land and disperse. The vessel should then be disinfected. The treatment of these cases of cholera, and of those under observation, should be carried on by the medical officer of health, or one specially deputed for this purpose; who, if possible, should possess some practical knowledge of cholera, not so much for the treatment of it, as for the diagnosis of the disease, as he is quite satisfied that there is such a symptom as a "cholera-look," and some even go to the length of a cholera-odor.

The detention above recommended would be quite unnecessary even in the instance of ships on which cases of cholera had occurred during the voyage, if there had been no fresh cases within forty-eight hours of arrival off the port.

In reference to local measures, he recognizes three conditions which are necessary for the development of a case of true Asiatic cholera: 1, the individual susceptibility at the time; 2, the effects of local unsanitary conditions, including overcrowding; 3, the concurrence of certain atmospheric conditions. Without the first two the third is innocuous; without the third, the first two are equally so; and without the first, the last two are innocuous.

Take the case of Alicante, in Spain, in July, 1884. The first two were undoubtedly present, but not the true cholera influence (though there were a few isolated or sporadic cases); the necessary concurrence of some specific atmospheric conditions was absent, and no outbreak was developed. In July, 1885, all three seemed to be present, and the appalling epidemic now raging is the result. The aim, therefore, of preventive measures should be to remove the first two conditions by improving the health of the population, and the sanitation of the locality; so that, if the cholera-influence which accompanies cases of the disease, or that due to atmospheric media or conditions, find its way into a locality, an outbreak is rendered most improbable, because the first two conditions are not present.

There seem to be some localities where the cholera germ will not develop; but one of the most favorable conditions for its propagation is overcrowding; hence, if the disease comes among us, and the residents of large cities would fly from it, let them select some secluded, high-lying, and healthy country place, rather than the fashionable summer resorts where great masses of people congregate.

The influence of food calculated to produce diarrhœa is dwelt upon, and we are told that "the mahapurshad, or holy food of Juggernauth, chiefly composed of melons in various stages of decomposition, the eating of which was a religious necessity to a pilgrim, too often produced a train of symptoms most favorable for the development of the cholera-influence, when no wonder the mortality was appalling. The abundance of fruit in Cashmere often works up the cholera-influence, if present, to an alarming outbreak; and when an early rise in some rivers, the sandy beds of which are devoted to the growth of melons, throws a vast quantity of this fruit into the market, ripe and unripe, with a population considerably underfed, if the cholera-influence be anywhere near, it soon finds a favoring soil, and an unaccountable (!) outbreak of cholera is reported. All this

points to the necessity of careful inspection of the meat, fish, vegetable, and fruit markets, and the removal and destruction of all meat, fish, vegetables, and fruit unfit for food, either from overripeness or from incipient decay."

In connection with the effects of impure water, we are told that the hill sanatorium in the Himalayas most liable to cholera, and which suffers the most from the disease, is Murree, a station also noted and dreaded for the frequency and fatality of its outbreaks of typhoid fever, due, without doubt, to the impurity of the water supply and the saturation of the soil for many years with injurious substances.

The usual suggestions in reference to disinfection of clothing closes this most instructive address.

FIRE-ARMS.

The strong *general* influence which the *family* physician possesses is unequalled save by that of the father-confessor.

This influence, more especially in rural circles, renders him a general adviser on all matters, those outside of the pale of medicine even.

This powerful influence should be used to induce persons not to have fire-arms indiscriminately about the house.

We realize that they are occasionally needed for self-protection, but the instances in which they are so used is infinitesimally small (in civilized communities) when compared with the number of cases where they bring death and sorrow to happy households. We can hardly pick up the morning paper without reading of some such accident. The most recent comes from Pine Creek station in this State, where a young man, shooting at a cat, killed his own mother, who was hidden from view by an intervening arbor.

Let physicians use their influence to stop this. An old boot would have dislodged the cat, and would not have killed the mother.

—Prof. P. Vogt, who succeeded Prof. Hueter in the chair of surgery at Greifswald, has died suddenly, in his forty-first year.

Notes and Comments.

Germain See on Asthma.

The Paris correspondent of the *Lancet* says that according to Professor Germain Sée, the only curative means against nervo-pulmonary asthma is "iodo-therapy"—that is, ioduration of the lungs and of the nervous respiratory system. But this method is not always tolerated, and patients are often induced to resort to the empirical remedies in vogue, all based on the combustion of certain substances and the inhalation of vapors thus produced. These vapors always contain a special substance to which the name of "pyridine" has been given. This substance is met with in all the products of the dry distillation of organic matters, of coal tar, of the principal alkaloids, in the fumes of tobacco, in nicotine, and in the animal oil of Dippel, from which it is ordinarily extracted. It is a colorless liquid, very volatile, of a strong, penetrating odor, miscible with water in all proportions, forming, with mineral acids, soluble bases, but unstable. Professor Sée endeavored to determine, experimentally, the physiological effects on patients suffering from asthma and from disease of the heart. The following are the conclusions of his work on the subject, which he lately presented to the Academy of Sciences:—1. Whatever the form or origin of asthma, ioduration constitutes the veritable curative method. When iodism intervenes, pyridine should be resorted to, but only during the fits. It is the best palliative, whereas iodine is the most efficacious remedy. 2. Pyridine is superior to the injection of morphine; its action is more durable and much more inoffensive. 3. In simple nervo-pulmonary asthma the fits cease completely. When the asthma is complicated with permanent pulmonary lesions, the duration of the treatment should be continued beyond eight or ten days to ensure relief. In cardiac asthma, with or without renal and dropsical complications, pyridine would render the greatest service in combating the most persistent and painful of the phenomena which accompany heart disease. The best mode of administering pyridine consists in pouring four or five grammes on to a plate, which is placed in a closed room, containing about twenty-five cubic metres of air. The patient, placed in a corner of the room, breathes the air impregnated with the vapors of pyridine. This treatment should be repeated for about twenty minutes three times a day. The absorption is immediate, and the pyridine can at once be detected in the urine.

The Action of Salicylic Acid in Rheumatism.

In the *Lancet*, June, 1885, pp. 1119, 1158, Dr. P. W. Latham enters fully into this question, and gives elaborate chemical tables, showing the changes that take place after the ingestion of this drug. Without attempting to reproduce the formulæ proving these changes, it will suffice to state that salicylic acid is changed into salicyluric acid, and thus hinders the formation of uric acid in the system. That salicylic acid, properly administered, does cure rheumatism and prevent cardiac complications, if given early enough, is an admitted fact, and the conditions which in acute cases ensure success are the following:

1. Pure salicylic acid must be given, the acid prepared from wintergreen only.

2. It must be uncombined with any base. One hundred grains of the acid mixed with fifteen grains of green acacia in powder and a little mucilage, and allowed to stand, harden, and are readily made into 30 pills.

3. Six pills, equal to a scruple of the acid, must be given thrice at intervals of an hour; and if the head be not affected, a fourth dose must be given, it being essential to saturate the system, until buzzing in the ears be produced. Afterwards, a scruple is repeated every four hours, if it can be borne. Usually 80 to 100 grains are sufficient, but some patients require 140 to 150 grains.

4. Forty to eighty grains are to be given daily for ten days, after all pain and pyrexia have passed away.

5. A strictly milk and farinaceous diet is to be enjoined.

6. The bowels are to be daily opened by 3 to 5 grains of calomel at bedtime, with a saline draught in the morning. This is most essential.

7. The bed should have light blankets, sufficient to keep the patient from feeling cold, as the object of treatment is to cool, not to sweat the body.

Is Intra-uterine Erysipelas Communicable?

Prof. R. Kaltenbach, in *Giessen Gynakol. Centralblatt*, viii. 44, p. 689, says that on the 31st of May a woman æt. 35, for the second time pregnant, was received into the lying-in wards. She had some time previously an erysipelas of both under extremities, which had started from an ulcer on the leg. On the 19th of June an erysipelatous inflammation on the right heel appeared, which spread over both legs. Here and there vesicles were found. The temperature exceeded 102.2° F. only once, and returned to normal on the 1st of July. At the time of the birth, which occurred fourteen days later, scales of skin still showed themselves on the under extremities. The puerperal period ran a quite normal course, with the exception that a small abscess formed in the region of the sacrum. On August 5, the patient with her child were discharged well. The child showed a desquamation on its head, neck, and thorax. In the course of the next few days the deeper parts took part in this desquamation.

For intra-uterine infection spoke:

1. The characteristic form and mode of spreading of the desquamation.

2. The time at which it occurred.

Therapeutical Hints.

Dr. John W. Martin says in the *Med. Press*, July 22, that the following is an excellent lotion for subduing inflammation, and reducing the œdema of the inflamed parts:

℞. Tr. opii camph. co.,	℥	ij.
Tr. tolutani,	℥	ij.
Liq. plumbi diacetat,	℥	iv.
Glycerine,	℥	ij.
Aquæ, ad.,	℥	xx. M.

A piece of lint or old linen to be well wetted with the lotion, and to be applied to the inflamed part. The wetting to be repeated at frequent intervals.

Internally, it is useful to combine the following mixture with the use of the foregoing lotion:

℞. Potass bicarb.,	℥	iss.
Tr. nucis vom.,	♏	xl.
Ferri am. cit.,	℥	iss.
Sp. am. aromat.,	℥	iss.
Aquæ, ad.,	℥	viij. Liq. M.

"℥j. three or four times a day."

He has found this treatment especially useful in those cases in which intense inflammation in the arms follows re-vaccination.

Prostatic Massage in Retention of Urine.

A very ingenious device is recommended by Dr. J. M. Le Rütte, in the *Weekblad*. The operation is performed by introducing the forefinger into the anus, and moving the prostate three times to the right, three times to the left, three times longitudinally, and then rubbing the surface. This proceeding causes some discomfort to the patient, and cannot be long borne. A gentleman above 50 years of age, who for a year had found increasing difficulty in passing water, was seized with complete retention. Neither soft nor metallic catheters could be passed. Nelaton's bougie was, however, introduced, and a great quantity of urine drawn off. A large prostate was felt per anum. After

twenty massages, with warm bathing every evening, he regained the power of passing water normally, and he has now had no difficulty for two years. A gentleman, aged 70, suffered in the same way. After fifteen massages a cure was effected, and the patient continues well. With both patients the massage caused some hæmorrhage from the prostate into the urethra, which an iron mixture was found quite sufficient to stop.

The Treatment of an Acute Form of Diarrhœa.

Dr. John Kent Spender tells us in the *Brit. Med. Jour.*, August 8, that more than thirty years ago a combination of laudanum and castor oil was much prescribed for "dysenteric diarrhœa," and he says that he has found the following formula extremely valuable for nearly all forms of sudden and acute diarrhœa, such as we often see in August and September. He combines about two minims of castor oil with three or four minims of solution of hydrochlorate of morphia (Brit. Pharmacopœia), and rubs them into an emulsion with gum acacia. To this he adds spirits of chloroform and a little syrup. This is the quantity for a single dose, which may be repeated every hour or two, according to the urgency of the case. If the diarrhœa is chronic, the quantity of the oil is increased, and if there is much pain, more morphia is prescribed. But when this mixture fails or does little good after four or five doses, it may even aggravate the malady to continue it. Warm milk and lime-water is the best food; a mustard poultice may be put on over the stomach, and there should be absolute rest in bed.

The Heart and Pulse in Acute Nephritis.

We are aware that in chronic Bright's disease, there is, after a time, usually a dilatation and hypertrophy of the heart, as well as a full, hard, tense pulse, indicating a high degree of vascular tension; but we have as yet heard but little of a like condition in the acute form of the disease.

Dr. G. Baumgarten calls our attention in the *St. Louis Courier of Medicine*, July, in an especial manner, to the fact that hard pulse and secondary hypertrophy of the heart is not at all uncommon in the acute form. He details several cases that have come under his experience, and says that in one case, of a boy aged 8 years, who had scarlatina, notwithstanding the urine was of normal quantity and contained no albumen, he made a diagnosis of acute nephritis, based upon a *large, tense, slow* pulse, some œdema of the lids, slight fever, pallor of the face, and loss of appetite. A week later the diagnosis was verified by the occurrence of violent uræmic convulsions, scanty, albuminous and bloody urine. As the case progressed to recovery, the peculiarities of the pulse gradually disappeared.

Sponge Grafts for Carbuncle.

In lieu of the old treatment of carbuncle by numerous incisions and the slow process of ulceration and sloughing, Dr. J. S. Grigley suggests, in the *Southern Med. Record* for August, a method that had proved very successful in his hands. In order to appreciate his treatment, it is well to bear in mind that carbuncles usually occur in those who are weak and debilitated, whose systems are "run down," whose reparative power is therefore below par. As soon as he is sure that there is a carbuncle, he freely cuts away all the implicated tissue, and scrapes the surface clean. He then places pieces of sponge (previously washed in a dilute solution of sulphuric acid, and kept in a 5% solution of carbolic acid) on the surface, saturating them in an ethereal solution of iodoform, 20 grains to the ounce. A piece of folded iodoform is laid over the sponge, then a thick sheet of absorbent cotton, followed by gutta percha tissue, and the whole secured by adhesive strips and a bandage.

Pregnancy and Labor Complicated with Fibroids.

After relating the histories of ten cases in the *Boston Med. and Surg. Jour.*, July 30, Dr. James R. Chadwick concludes with the following propositions:

As aids to *diagnosis*, the following points should have great weight:

1. An area of flat percussion beyond the limits of the tumor or tumors.
2. Unduly rapid growth of a fibroid.
3. Bluish discolorations of the vaginal entrance.

As to *treatment:*

4. That intra-uterine disinfectant douches should be administered throughout the puerperal period in all cases, even before the supervention of symptoms.

As to *prognosis:*

5. That fibroids are, as a rule, absorbed during involution of the uterus, or soon after.

Intestinal Obstruction by Piece of Beef Bone.

In the *Texas Courier-Record of Medicine*, Dr. C. L. Gwyn says that on February 1, 1883, N. T., aged 51, white, applied to him for relief of a sharp, lancinating pain about the anus. Examination

revealed a spicula of bone one inch and three-sixteenths long, wedge-shaped and jagged. It was caught by its sharp end in one of the folds of the rectum, just above the internal sphincter muscle, and was swallowed while eating soup some days previous. It was easily removed by forceps and speculum. There are two similar cases on record in *Med. Archives*, November, 1869, St. Louis.

To Keep off Mosquitoes.

The effectiveness of the following mixture in keeping off mosquitoes is vouched for by "The Angler:"

Three parts olive oil.
Two parts oil of pennyroyal.
One part glycerin.
One part ammonia.

To be well shaken before applying to face and hands. Avoid getting the mixture into the eyes.

CORRESPONDENCE.

Tying the Navel Cord.

EDS. MED. AND SURG. REPORTER:—

In the REPORTER of August 8th, 1885, Dr. J. Gilbert Young invites criticism on the treatment of his case of umbilical hemorrhage.

If the cord was a thick, hard, unyielding one, it is probable the hemorrhage was due to its rapid desiccation, whereby the pressure of the ligature was relieved, and the vessel left patulous.

He ligated the cord while it was filled with blood and gelatin, and perhaps while it was still pulsating, and then, as soon as the constriction of the ligature ceased through the process of oozing and drying, the full vessel would naturally bleed from arterial or heart pressure.

Though the hemorrhage may not have been due to that, but to some other cause, I claim his method of treating the cord, as set forth in his article, is erroneous and defective.

Why will doctors continue to follow the old well-worn groove of past generations, which is devoid of common sense, and has no practical reason to commend it? Why tie the cord before severing it? What is the use of stripping or trying to strip an uncut cord? What is the idea of having a ligature on the placental end of the severed cord?

To be sure Clay, of Birmingham, in his Obstetric Operations, gives a cut of how to tie the cord, with an absurd excuse for the use of the placental ligature—that of "cleanliness;" while Bedford, on the other hand, gives a very plausible reason for omitting it, viz: that of "emptying the placenta and reducing its bulk."

To those interested in the subject, I recommend the following, which I believe to be the best method of preventing those unfortunate cases of fatal umbilical hemorrhage:

Wait until all pulsations in the cord cease before severing it, then cut the desired length, and strip the stump well of blood and gelatin, holding it firmly near the navel between the left thumb and index finger.

After that manipulation is completed, it can be ligated if so desired, with the common round white cotton wrapping-twine. I have found no advantage in the flat braid, even if Bedford does recommend it.

The cord of the brute animal is not ligated, and I have yet to hear of a fatal case of umbilical hemorrhage in them; and I believe if the cord of the human animal is similarly treated, there will be no fatal hemorrhage either.

When there is a thick hard cord, we must expect hemorrhage from the stump if we ligate hurriedly and then sever. To be safe in those cases, we must wait until the vessels are emptied and collapsed before we ligate.

Through inexperience I had a fatal case during my early practice, by not waiting sufficiently long before ligating. The cord was large and hard, and I made little impression on it in my efforts to strip after I had severed it. I ligated, and an hour after I left the house the hemorrhage was detected. The child lived a few hours.

The stump should never be dressed or compressed, but allowed to dangle, drying gradually without grease or other applications.

I have endeavored to enlist the attention of practical men to this subject by articles in the REPORTER of January 3d, 1880, and May 2d, 1885. I have also prepared a lengthy criticism on the treatment of the newly-born child, in which I attempt to show the unscientific teaching of some of the leading obstetric writers, from Smellie to Lusk.

I am of the opinion that eminent teachers are averse to innovations in these cases, as they continue to recommend ancient customs, which to me are devoid of practical common sense.

So far the populace are gradually rejecting some of them, for instance Smellie's warm flannel cap.

W. J. CRAIGEN, M. D.

Cumberland, Md., August 24, 1885.

Hard to Kill.

EDS. MED. AND SURG. REPORTER:—

On August 10, 1885, I was called on Stone Hill by telephone, to see a dying man. My protestation that I could be of little or no good to a person in that condition proving of no avail, I drove to Stone Hill, nearly five miles from Warren, occupying nearly an hour. Found my man lying by the side of an oil derrick, nearly covered with blood, his head being supported by a companion, who gave me the history of the accident. Henry Sutton, age 42, and companion, were agitating an oil well, and when Sutton saw oil escaping he told his companion to attend the engine and he would shut off oil. The engine was not stopped soon enough, as the polishing rod rope was snapped off in the crown pulley, and while Sutton was turning off the stop-cock, using his right hand, and leaning his body over towards his left to escape the jet of oil, the polishing rod (an iron bar 20 feet long, $\frac{3}{4}$ of an inch in diameter, and blunt at both ends,) came down from top of derrick 74 feet high, and struck Sutton one and one-half

inches back of and two and one-half inches below right ear, passing under the sterno c. mastoid muscle, and obliquely across the neck to the front, striking the manubrium on its under surface, and crossing over struck the cartilages of first two ribs, nearly if not quite separating them from sternum, came out of chest one-half inch below and one inch to the right of nipple of the left breast, struck the left thigh six inches below the anterior superior spine of ilium over the rectus femoris muscle, which it penetrated, and came out at the lower and outside of thigh five inches from external tuberosity of femur, penetrating ground about eight inches. Five feet eleven inches of rod passed through neck and chest. Entrance to exit of chest wounds measures sixteen inches, and thigh wounds eleven inches apart. I made a stretcher out of two-inch boards (stretcher weighing more than the man did), and with the help of four men carried him down the mountains nearly a mile to nearest house, where his clothing was removed and his wounds antiseptically dressed, and liberal doses of brandy and morphia were administered, hot bottles placed around him and used active measures to get him over shock. He rallied, and maintained he was going to get well, and would not talk of dying. The first two days after injury he suffered intense agony at every attempt at swallowing. For three days I thought he would die from inflammation of the left lung. Every cough, though under the influence of morphia, seemed to pain him intensely. On the sixth day after injury his temperature was normal, and pulse 78 beats per minute. Temperature and pulse have remained normal ever since, and yesterday, the 25th, he was sitting up, with all the indications of gaining strength rapidly. Now when I hear of the case recorded in Dalton's Physiology, of the man with a crow-bar through his brain, I will relate how a man with *luck* and *pluck* escaped with his life from equally as wonderful an injury.

RICHARD B. STEWART, M. D.

Warren, Pa.

Hemorrhage from the Umbilical Cord.

EDS. MED. AND SURG. REPORTER:—

In your issue of August 8th, I notice a case reported by J. Gilbert Young, M. D., of fatal hemorrhage from the umbilical cord.

The hemorrhage perhaps was not from the end of the ligated cord, but similar to the following case which came under my care:

In 1881, September 22, I was called to attend in her fourth confinement, Mrs. M., who in a few minutes after my arrival (having been in labor about one hour) was delivered of a large, healthy female child, which was washed and dressed before I left the house. Shortly after reaching home, distance about half a mile, I received a message to return, as the babe's clothing was becoming wet with blood. On reaching the house, I found the babe's clothing in region of cord well saturated with blood, and upon removing them found the hemorrhage had ceased, cord well ligated. I made traction on the cord and examined it without finding any evidence as to where the hemorrhage came from. Thinking that the cord might not be thoroughly ligated, I applied another ligature. The nurse proceeded to dress the babe with dry clothing, and I left, but was not in my office half an hour until I received another call, and upon reaching my little patient I found the hemorrhage had been greater than the first, and the child almost lifeless. Again removing everything, I found the hemorrhage had ceased, and the cord and surrounding parts were clean and dry, the clothing having absorbed the blood; being satisfied that the cord was thoroughly ligated, I again examined along the cord and point of attachment to abdominal wall, which was very much retracted, with heavy folds of skin around it. I failed to find a point from which the hemorrhage came, and was about to pass the babe to the nurse, when there commenced to ooze up along the cord upon the left side some blood. Without disturbing the parts, I passed my artery forceps down along the cord, took a free grasp of the parts on that side, drew them up enough to get a silk ligature on, after which we had no more hemorrhage, and with good care the babe recovered.

J. C. CLAUDY, M. D.

NEWS AND MISCELLANY.

The American Dermatological Association.

(*Concluded from page* 306.)

FRIDAY, THIRD DAY, MORNING SESSION.

REMARKS ON ELECTROLYSIS AND OTHER PRACTICAL TOPICS,

by Dr. C. Heitzman, New York.

The reader spoke very highly of electrolytic epilation. For this purpose he uses the Leclanche battery. Six cells of this battery have the advantage of steadiness, lack of pain and lack of reaction when applied to the face of the patient. He employs a needle devised by Leiter, of Vienna, which permits the depth to which the needle penetrates to be measured.

He has had good results from electrolytic destruction of dilated blood-vessels in the face, less satisfactory results in the treatment of port-wine marks, where a permanent cure is only exceptionally attainable. Sodium æthyl is highly recommended by some for the destruction of angioma of the face, but it is in no way superior to nitric acid.

The speaker maintained, after observing two hundred cases of falling of the hair, caused by seborrhœa, that the method he recommended in 1876 gave fair results. This is the application of a ten or twenty per cent. ointment of crude oleum rusci in vaseline and paraffine.

For the removal of freckles, the doctor used an ointment recommended to him by Wertheim, of Vienna. The preparation is as follows:

℞. Hydrarg. ammon. muriat., grm. 75.3.
Magist. bismuthi, 3.5.
Ungt. glycerina, 30.0. M.

This is is to be applied in a thin layer every other night, and in four or six weeks the result is highly satisfactory. As to the permanency of the cure the doctor was unable to state.

In regard to the reappearance of hair after removal by electrolysis, the speaker considered it to be due to the growth of the fine hairs, which was increased by the transference to them of the nutrition which should have gone to the hairs removed.

Dr. Wigglesworth for the past fifteen years had used for freckles the following ointment, which was almost identical with that mentioned by that Dr. Heitzman:

℞.	Hydrarg. ammon.,	parts 10.
	Bismuthi subnitratis.	" 10.
	Vaseline,	" 100. M.

ON SYPHILITIC RE-INFECTION.

By Dr. R. W. Taylor, Mew York.

The speaker first referred to the literature of the subject and gave a brief review of the authentic cases on record, giving the names of the reporters. The number of cases previously reported is between thirty and forty. To these the speaker added the histories of three more. A fourth case has been observed by him, but as the complete history was not prepared, it was not given.

Case 1. A bar-keeper aged 25 years. Was first seen in 1868 suffering with gonorrhoea. Three years previously had had indolent enlargement of the lymphatic glands in the groins. Examination showed the presence of lymphatic enlargement in certain regions. Inquiry into the history showed the existence of a chancre three years years before, which had been slow in healing. About two months later he became sick and suffered with a roseolous eruption, sore throat, falling off of the hair, and rheumatic pains, worse at night. Under the treatment he improved, but afterwards exhibited a papular eruption. He was then seen by Dr. Van Buren, who pronounced the case one of syphilis, and ordered mercurial treatment. He recovered after two years, but of his own accord continued the treatment two years longer. He then remained well until the attack of gonorrhoea.

In February, 1870, he again appeared, presenting a typical indurated chancre on the cutaneous aspect of the pubes. It presented every evidence of a primary infection. Later a papular syphilide appeared over the body. There were several mucous patches on the pillars of the fauces, and the throat was red and swollen. The joints soon became the seat of nocturnal pains. The patient also presented a form of syphilitic epididymitis. Under mercurial treatment, there was some improvement, but a year later there were some tertiary manifestations. By 1874, he seemed very well. During the next three years, there were no evidences of syphilis, but he continued the mixed treatment.

He was again seen in the fall of 1882, when it was learned that his good health had continued, and that he was the father of a healthy child. The child was examined and no evidence of hereditary syphilis detected.

Case 2. Had in June, 1873, a typical indurated chancre, followed by distinct secondary symptoms, which disappeared under treatment. He then passed from observation. In February, 1874, he presented several ulcero-tubercular lesions on the outer aspect of the forearm. He then remained under treatment six months. In January, 1875, he had spots of thickening of the periosteum of both tibiæ. He was again treated with benefit.

In June, 1876, there was a typical indurated nodule on the prepuce, from which indurated lymphatics extended to the inguinal lymphatic glands. The incubation of this sore had been about twenty days. This was followed by malaise, sore throat, swelling of the post-cervical and epitrochlear glands. Over the body and arms there was a fine mottling of light-pink color. The patient then went to Europe, and was not seen until March, 1885, when it was learned that the symptoms had been well marked, and that he had been under treatment for them with several continental physicians.

Case 3, age 41, had had a typical indurated chancre in 1874. There had been inguinal adenitis, followed by roseola, falling of the hair, and later by severe iritis of the right side. He was treated with mercury.

In February, 1882, he returned with a typical hard chancre. In April, he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide. In May, inflammation of the iris of the right eye again appeared. In 1883, he had a late secondary rash.

These cases were reported with the object of throwing some light upon the natural history of second infections of syphilis. In all these cases, relapsing indurations were carefully excluded.

OBSERVATIONS ON THE OLEATES,

by Dr. H. W. Stelwagon, Philadelphia.

In regard the chemistry and preparation of the various oleates, both as to their manufacture by the direct combination of the acid with the base and by double decomposition, almost, if not entirely, as much can be found in the English translation of Gmelin's Handbook of Chemistry, published 1866, as in the writings of the past several years.

Of all the oleates, those of mercury, zinc, bismuth, and lead, have a place in the treatment of diseases of the skin, and in view of their costliness, the seeming unavoidable frequency of badly made preparations, the disagreeable oleic acid odor, and the irritation so frequently observed following their use, it is probable that of these four the mercuric oleate promises to retain a permanent value. This last is especially valuable in ring-worm of the scalp, but for inunctions in the treatment of syphilis it is of doubtful utility, as it is questionable whether it is absorbed. Oleate of copper, which has been so highly recommended for ring-worm of the scalp, is not comparable in that affection to oleate of mercury, or to tar and sulphur preparations.

Dr. Wigglesworth had practically renounced all oleates except the oleates of zinc, lead and mercury, as a parasiticide.

Dr. Duhring had employed the oleate of copper in varying strength in thirty or forty obstinate cases of ringworm, but it seemed to exert no influence whatever. As to its efficiency in acuter forms of ringworm, he could not speak.

Dr. Hardaway had almost entirely discarded the oleates. In some recent cases, the oleate of copper has seemed to be successful, but in chronic cases it entirely failed.

A CASE OF SYPHILITIC APHASIA AND PARAPLEGIA, FOLLOWED BY DEATH, WITH AN ACCOUNT OF THE AUTOPSY.

by Dr. L. N. Denslow, St. Paul, Minn.

The object of the author was simply to put on record a case in which an autopsy was obtained in early syphilitic cephalalgia. The patient was seen in consultation April 29, 1885. Two months previously the patient had begun to suffer with severe headache, worse at night. There was also a papular eruption. He acknowledged the existence of a sore six months previously. Iodide of potassium with chloral had been given two weeks later; the patient was free from pain, but it returned one month afterwards, when the patient stopped taking medicine. Iodide of potassium was again given, with the effect of relieving the pain. Aphasia and paraplegia then developed, and the patient died four days later, and within nine months of the initial lesion.

At the autopsy, the dura mater, along the superior longitudinal sinus, was thickened and adherent. There were numerous small gummata in the pia mater, situated along the right border of the longitudinal sinus and extending back to the fissure of Sylvius. The pia mater exhibited the evidences of simple acute inflammation.

Adjourned.

The Laws of Maternity.

(*Corset-Bound Mothers.*)

In connection with our editorial on this subject in the last issue, we quote that we may endorse, the following sensible remarks in the *Daily Press* of this city, September 9th:

At a certain popular watering-place this summer, the number of infants has been particularly noticeable. Babies large and small, pretty and homely, richly-dressed, healthy babies, puny babies—babies were everywhere. It was a beautiful sight to behold, and every heart softened in their presence.

"But," said a wise old lady, in remarking upon the uncommonly large number of young infants in the place, "there is scarcely one in ten of these babies which is not brought up on the bottle. I don't know what ails the young mothers nowadays, that they can't 'nurse' their children. It makes hard work all around, and the babies are ten times more likely to die in the bringing-up. I've heard good doctors say that a child brought up on the bottle never makes so strong a person when he's grown up any way, and that sounds reasonable. 'Tisn't nature to bring up dear little babies this way. We can all see that."

The kind old lady's words made a profound impression upon at least one of the half-dozen women who heard her. A somewhat extended privilege of observation had served to show that the watering-place which she referred to was not singular in the peculiarity which had been remarked. America is full of bottle-fed babies among its so-called "higher classes." It hardly seems as though the German spirit of contempt for a well-bred woman who suckles her offspring, and which has made that faithful mother, the Crown Princess, so unpopular—it hardly seems that that spirit can prevail largely in our republic. Most of the young mothers who have come under our observation "wish" that they could "nurse" their little ones, but their physical condition is such as not to render such a course advisable. And why should this be so? Walking along the thronged beaches of the pleasure resort, a solution of the problem presented itself. Bevies of young women were visible on every side, whose slender figures were many of them painfully constricted in obedience to the prevailing fashion, all of them far too closely confined.

Do you know, women of America, that thousands and thousands of beautiful and beloved infants die every year because their mothers have systematically for years worn their clothes too tight?

"Oh yes!" you reply. "We all believe that, but *I* have never done so. The reason why I could not 'nurse' my baby was because I could not take enough into my stomach when he was born to make nourishment for him. No one thought for an instant that my figure had been too tightly compressed."

But how did your stomach become so weak that, at a time when all the instincts of your nature should have combined to spur it up to greater and more successful efforts than ever before, it utterly refused to act, and your baby was, therefore, robbed of its rights?

But, after gazing upon the unnatural forms of the women—young and middle-aged—upon the promenades, one wonders no longer not only why women cannot provide the milk heaven makes for the proper rearing of the young of the human race, but that those unfortunate little beings even can be born alive at all. Think of wearing two stiff, hard corset-steels, constantly pressing down with a weight of many pounds to the square inch upon the delicate tissues of the stomach and its tributaries, through a series of years! Yet the capacity of the stomachs of our young girls is one-third, perhaps one-half, reduced by the pressure brought to bear by these corset-steels, while the working force of the digestive organs is impaired by them beyond compute. The fierce and irresistible demand of young, nervous natures manages to insist upon tolerably efficient action of the vital organs during periods of ordinary strength; but when the constitution has undergone the strain of maternity, what is there left? The poor, long-abused stomach utterly refuses to come to the help of the innocent baby for whom the mother would willingly lay down her life, but for whom she cannot bear the senseless scorn of the unthinking world.

Even if there were no cruel steels pressing down upon the tender stomach and bowels, think of the constriction brought to bear upon the great ducts which carry the lacteal fluid to its destination. How can they perform their function under even a moderate pressure? They can act properly only when the waist is utterly free from constraint—as free as in a nightgown!

"Oh," you say, "you speak too strongly. Corsets are not so bad. If they were, how could so many excellent women and physicians favor them? Besides, many women who have always worn them suckle their children, who are strong and healthy."

These women in the classes of which we speak are the exceptions. One cannot argue from ex-

ceptions. And as for those "excellent" people whose advice and countenance are perpetuating this deep-seated evil—this clinging superstition, so fatal to woman's health and progress—may heaven have mercy on them and open their blinded eyes!

Cholera Inoculations.

We have nothing new of a definite nature to offer in reference to the value or uselessness of Dr. Ferran's inoculations. As contributing to the history of the question, we quote from the Spanish correspondent of the last issue of the *Brit. Med. Jour.*, who sends the text of a card which Dr. Ferran hands to each of his clients. On the face of the card is the number in the register, and the name of the individual who has been operated on (Método Ferrán). On the back of the card is the following notice, contained in nine paragraphs:

1. As inoculation against cholera is confirmed by laboratory experiments, we cannot present it in any other way to the public.

2. This operation has been founded on scientific principles, which led the eminent Pasteur to discover inoculation for carbuncle, etc.; these being proved experiments, are now admitted as positive facts.

3. Inoculation against cholera, like all other precautions, cannot absolutely prevent attacks of this disease; in a case in which the attack takes place, it will probably be light. Neither can inoculation absolutely prevent death.

4. It is probable that the immunity due to anti-cholera inoculation is not of unlimited duration. The same happens with other lymph; for example, that of small-pox. In any case, the anti-cholera lymph will preserve its efficacy for a length of time that experiments have not yet practically determined. It is further necessary that inoculated persons should present themselves for re-inoculation before the expiration of ten days.

5. Since the anti-cholera lymph requires a certain time in order to secure safety to the person inoculated, it should be understood that a fresh cholera attack occurring within the first five days after inoculation is beyond the protective influence of the lymph, the efficacy of which cannot be assured until this time has passed.

6. The existence of a cholera epidemic is no argument whatever against inoculation; on the contrary, it is more than ever important, just as in the same way with the vaccine of cow-pox during the epidemics of small-pox.

7. The anti-cholera lymph can never prove the cause of an attack of cholera.

8. None of the so-called preservatives against cholera, up to the present discovery, offer to scientific men the same guarantee as preventive inoculation.

9. Persons in a position to prove their poverty will be inoculated gratis.

Too Many Drug Stores.

At the recent convention of the American Pharmaceutical Association, Mr. Mahlon N. Kline, of Philadelphia, chairman of the drug market committee, read a long report on the state of the drug market. He said that there were too many drug stores in the country. The business was now unprofitable, mainly for the reason that patent medicines were handled by nearly every storekeeper and grocer in the small towns. The physicians were charged with helping this patent medicine business along. They would prescribe these patent medicines for their patients from a knowledge only of what the advertising circulars contained of them. The output of graduates from the medical colleges was far in advance of what was needed. He wanted a line drawn somewhere.

Mr. Henry Meineger, of Brooklyn, New York, a retail druggist, sent some very warm shot into the ranks of the wholesale men. His particular plaint was that they got up preparations of their own and scattered them broadcast through the country, thereby injuring the retailers. Mr. Painter, of New York, said that proprietary medicines are now handled by the grocer, the saloonkeeper, and the dry goods dealer. The pharmacists get the cream of drugs from the wholesale house, while the musty, imperfect drugs went into the laboratories of those who manufacture proprietary medicines.

A delegate read an extract from a San Francisco letter, which asserted that druggists are compelled to pay sixty per cent. of the gross receipts as commission to the physicians who patronize them.

The following officers were elected for the ensuing year:

President—Joseph Roberts, of Baltimore.

Vice-Presidents—J. H. Hallister, of Madison, Wis.; A. B. Prescott, of Ann Arbor, Mich.; James S. Evans, of West Chester, Pa.

Secretary—J. M. Maisch, of Philadelphia.

Treasurer—C. A. Tufts, of Dover, N. H.

Reporter of the Progress of Pharmacy—C. L. Diehl, of Louisville.

Small-pox.

Recent advices state that small-pox has reached Sutton, Quebec, a town eight miles from Richford, Vt., and fears are entertained that it will reach there. Sleeping-cars between Boston and Montreal are now detained at Richford on the trip from Boston, and are not allowed to enter Canada.

A young woman afflicted with small-pox was found on the streets of Ottawa recently, having just arrived from Hartwell's Locks. She was at once taken to the Contagious Disease Hospital.

The official report of the Health Office of Montreal for one day recently shows twenty-three authenticated cases and twenty-three deaths. About two hundred French-Canadian operatives employed by the Adams Tobacco Company, who struck rather than be vaccinated, have been induced to return to work.

The Acting Postmaster-General of the United States has requested the Canadian Postmaster-General to order all mails from Montreal to the United States to be thoroughly fumigated before dispatch.

A Dudish Offspring.

When we put one and one together, when we mate the "Newport youth" with the "corset-bound" woman, we would suggest as a question in evolution what will be the result. The "New-

port youth" is thus described in one of our lay contemporaries:

"He begins his day with a cup of coffee or a brandy cocktail at 8 a. m.; then he turns over and takes another nap till 11 or 12, when he indulges in a breakfast of eight or ten courses. But though he eats like the anaconda, he cannot rest like that sagacious animal. He next plays lawn tennis, or walks to his club and indulges in poker or whist at $5 a point. After this he accomplishes the incredible feat of walking home, of which he is extremely proud, and which, perhaps, he can do better at this hour than he could later in the day—or night. About 5 o'clock he drives out, or is driven out, perhaps drops in and bores himself at a few afternoon teas. Then he dines somebody, or is dined himself. Next he goes to the Casino or whatever ball is on the tapis. No matter how late the hour, however, he really is obliged to drop in at the club and stay an hour or two, talking over the day."

Athletics at the University of Pennsylvania.

Training for different sports and physical exercise of all kinds will be directed during the coming college year by Mr. Pennell, an original member of the New York Athletic Club, who will act under the general superintendence of Dr. J. William White, physical director at the University. Mr. Pennell is an athlete of note, and has the best record for dumb-bell lifting.

Since increased attention has been given to physical education, the need has been felt of a fully equipped gymnasium, resources having been meagre in that direction. It is proposed to build a handsome gymnasium on the new Athletic grounds, the edifice to cost, equipped, from $50,000 to $100,000. To take the place of this building meanwhile, the College assembly room, which has long been the scene of "corner fights," etc., and a general loafing place for students, has been cleared. About $2,000 will be expended for equipments, which will include the best of modern appliances for physical development. Several devices patented by Dr. Sargent, of Harvard College, and in use at the Heminway Gymnasium, will be procured. It is expected that everything will be in working order by the first of October.

The International Congress.

At a meeting of the Chester County Medical Society, held at West Chester, September 8, it was unanimously "resolved that it is the judgment of this society that, while the American Medical Association has a perfect right to enforce its code of ethics upon all associations subordinate to it, it has no such right as regards the International Medical Congress, a body with which it has no fixed connection and which does not undertake to regulate such matters of professional ethics; that the attempt to organize the Congress solely from its own membership and that of its subordinate associations was most unwise and inhospitable, and calculated to lessen the influence and usefulness of the American Medical Association; that we hereby instruct delegates to the next annual meeting of the American Medical Association to use all honorable endeavors to see that the false step taken at New Orleans shall be retraced, and that those who led the Association into the present folly shall not be intrusted with the arrangements for the International Congress."

Unhealthy Meat.

At the meeting of the Butchers' and Citizens' Protective Association in this city recently, it was resolved that a committee be appointed to wait on Major Veale and Dr. Ford, of the Board of Health, and ask them to address the Association on the subject of diseased and unhealthy meats.

The Association meets weekly, and expects to form a permanent organization at its next meeting. They have already the names of 130 butchers, and expect about 1800. The object of the Association is to suppress diseased and unwholesome meat. A petition is to go before Councils praying for the election of meat inspectors. Many diseased cattle are shipped here in a dressed state, the condition of which it is impossible to tell without skilled inspection. A butcher said that of those coming here dead, many would not have borne transportation alive.

Love of Pathology in Egypt.

Egyptian medical men, at times, evince a remarkable eagerness for the study of pathology. A poor man recently died in a village in Lower Egypt, from a compound fracture of the skull. The resident sanitary medical officer inspected the body, and stated that it would be necessary to perform a necropsy to ascertain the cause of death. The friends of the departed had a strong objection to this course, but not until they promised to pay the medical man $10 did he agree to relinquish his intentions. The uncharitable people of the village were of the opinion that the medical man had no sincere wish or intention to perform a necropsy, but announced the obligation of doing so in order to extort money.

Tallow-rendering a Nuisance.

Medical Inspector Taylor recently reported to the Board of Health that he had inspected the premises on Pennsylvania Avenue, below Sixteenth street, in this city, occupied by the Butchers' Tallow-rendering Association, and found that about 30,000 pounds of tallow are received weekly, some of which is sold to oleomargarine manufacturers, but a large portion is boiled in the establishment. The fat fumes are discharged into the atmosphere, and create a nuisance prejudicial to health. The inspector suggested that the association be required to render its tallow in a steam-tight, jacketed tank, in order to obviate the nuisance.

The Sunday Liquor Law in Pittsburgh.

Clergymen and others at Pittsburgh have so vigorously insisted upon the enforcement of the laws against selling strong drink on Sunday that the indicted saloon-keepers have offered to compromise by paying half the costs of suits begun and signing an agreement to suspend Sunday business. The prosecutors, however, are so encouraged by utterances of Judge Ewing, that they refuse to compromise.

Smoking in Bed.

The dangerous practice of smoking in bed has been repeatedly condemned, yet until the man who *blows* out the gas has been become extinct, we may expect to hear of the man who smokes in bed. *This time it is a woman.* An actress in New York was recently smoking a cigarette in bed. Naturally she fell asleep. The other inmates of the house were aroused by cries for water, they found her in flames, and the mortuary reports of Bellevue Hospital, the next morning, contained her name.

Scientists Organizing for Research.

Many of the more advanced of the American political economists have formed an organization for mutual support and encouragement in the conduct of economic research. Professor Henry C. Adams, of the University of Michigan, is chairman, and Professor Richard S. Ely, of the Johns Hopkins University, is secretary.

Infected Hotels.

The Iowa Supreme Court has decided that a hotel keeper who receives guests knowing that there is a contagious disease in his house, is liable for damage to any guest who may contract the disease.

Errata.

In the second paragraph of the article on "Ligating the Umbilical Cord," published in REPORTER of September 5, after the remarks on the number of threads composing a proper ligature, the words *Number* 20 should read NUMBER 40.

Patriotic Triplets.

Of three children born to one mother in Harris county, Ga., a few days ago, a boy bears the name of Cleveland, a second boy that of Hendricks, and a girl that of Queen Victoria.

OBITUARY NOTICES.

FRANCIS D. CUNNINGHAM, M. D.

Dr. Francis Deane Cunningham, one of the most prominent physicians of Richmond, Va., died September 9, aged 49 years. He was a son of Dr. John A. and Eliza (Dillon) Cunningham, and a grandson of Edward Cunningham, of Churchill, county Down, Ireland, who emigrated to this country in 1784. He graduated in medicine from the Medical College of Virginia in 1857, and subsequently attended a course of lectures in New York, receiving again the degree of M. D. in 1859 from the Medical Department of the University of New York. Going thence to Europe, he made a special study of ophthalmic surgery in London and Paris. He had been Professor of Anatomy in the Medical College of Virginia, and President of the State Medical Society. In 1876 he was a delegate to the International Medical Congress in this city. He served in the Confederate army during the war, belonged to many scientific bodies, contributed ably to medical literature, and held many positions of trust. In 1864 he married Agnes Campbell, daughter of Bazil Gordon, esq., of Caroline county, Va.

Items.

—The London medical press is divided, like our own, as to the questions arising from the International Medical Congress in Washington. The *Lancet* sides with the present acting committee.

—*Godey's Lady's Book* for October is a brilliant number, opening with a handsome steel engraving of "The Lady of Lyons." This picture illustrates the story of Bulwer's famous drama of that title, which has been carefully transcribed for the magazine in a narrative form.

—Henry W. Fisher, a respectable resident of Huntingdon, of Presbyterian extraction, believes in spiritualism, and announces that his daughter Bertha, aged 12, though unacquainted with the German language, recently spoke fluently in that tongue upon the occasion of her being possessed by the spirit of a German musician.

—Jay Gould is physically not very imposing. He reminds one of what the girl just returned from a Boston school said when she saw a steam fire engine in operation. "Who would ever have dweamed that such a vewy diminutive looking concern would hold so much watah?"

—"Yes, indeed, Brown is a very sick man."

"When was he taken ill?"

"Yesterday morning I was called to attend him."

"Ah, that accounts for it."

And now these two physicians pass each other as perfect strangers.

—A proposal has been made and patented to use a solution of lactic acid and glycerol in water, for the purpose of soldering the tins in which tinned provisions are put up, this solution being harmless, and acting as an efficient substitute for the poisonous chloride of zinc which is commonly used.

—The aching of a carious tooth may sometimes be instantaneously arrested by filling the cavity, after cleaning and drying it, with a mass made of 1 part each of dry alcoholic extract of opium, camphor and balsam of peru; 2 parts gum mastic, and 20 parts of chloroform. So says Dr. Ludovici in the *Farmac Italiana*.

—The Rumford Chemical Works, Providence, R. I., manufacturers of Prof. Horsford's Acid Phosphate, have recently purchased a commodious building and warehouse near their present location, where they propose to move their business a few months hence. This purchase has been necessitated by the demands of their large and increasing business.

—J. G. Otto (Pflüger's *Archiv*) finds arterial blood richer in sugar than venous, the total reducing agent being the same in both, so that there is a reducing agent in blood in addition to sugar. There is a marked increase in the reducing agent contained in the blood of persons under the influence of chloroform, chloral, and morphia. The blood of the child at birth contains about the same quantity of sugar as that of its mother.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

TÆNIA.*

BY WM. E. DOUGHTY, M. D.,

Of Hartsville, Pa.

The presence of intestinal worms was known to and described by the very earliest medical and scientific writers. In all probability these parasites were coëval with the advent of man, and possibly were a necessary cotemporary creation. With what we know of them, and have known of them, they keep neck and neck in the race and with the race. Not more than about three varieties of intestinal parasites were known to and described by the ancients. Nor were there but few kinds known before the present century. Our present knowledge of these loathsome parasites places the number of different varieties at about fifty, which take up their habitation in man. Twenty-one of this number pitch their tents in the intestinal canal. Of this apparently large number of tenants, nine of them compose the tape-worm family, seven the round-worm tribe, three are the infusoria, a class which is microscopic, and the suctorial are two in number. It is not improbable that the parasites of the human family may increase as creation and science advance, and the different peoples of the world come within the sphere of research. Not nearly all of this array of worms are peculiar to man; eight only are such—three of the tænia and five of the round-worm tribe. The others are inhabitants of various animals, and from known and unknown causes, but occasionally getting translated to man, and tarrying, as it were, awhile at Jericho. All ages and sexes are alike disposed to these parasites, and the infant, the adolescent, the middle-aged, and the aged, are subject alike to be the host or hostess of a colony of intestinal parasites. The person who is the host of a single *pediculus humanus*, the fact being known or even suspected, will inevitably be under the ban of social ostracism. But worms are no barrier to good society, and this is a palpable exception to the axiom, "evil associations corrupt good manners." But these are nice distinctions, which, like hairs, divide the N. from the N. W. side. Omne vivum ex ova, as all things come from an egg or germ, the necessary condition for the parasitic development is the introduction of eggs or embryos into the intestines. The mostrational and common way in which this is effected is by means of the food eaten. Raw or uncooked meat is the most prolific means of introducing the tænia.

The theory of spontaneous evolution, or that certain conditions and substances have a tendency to breed worms, needs not in these days of advancement even a passing notice. The popular belief and parental caution, that sugar-eating children are worm-breeding children, is as fallacious as it is popular. No eggs or embryos, no worms, although the breaths with sweetmeats tainted are. The older writers wrote of a morbus verminosus and a worm disease without the presence of worms. Credulity is rampant. People whose note I would take for any amount, and know that they would pay it at maturity, say

*Read before the Adjunct Montgomery County, Pa., Medical Society.

that under certain geographical and climatic conditions a bushel of sawdust will, in twelve hours, be a bushel of fleas. This is not more incredible than that all saccharine substances will evolve intestinal parasites. Omne vivum ex ova. There are many conditions which may be either favorable or hostile to the propagation of the parasites, as disease, personal conditions, occupation, cleanliness, climate, or the season of the year. Diseases which augment the peristaltic motion, are hostile to the incubation or alternation of the eggs, or embryos, which do not get the quiet necessary for their development. As soils are peculiarly fitted to produce in their greatest luxuriance certain grasses, grains, or vegetables, so certain personal conditions may be more favorable than others to produce worms. Occupation is likely to have as much to do with fostering the development of intestinal parasites as any other cause. Butchers and cooks, or those who are engaged in the handling of meats, or animal food, are especially disposed to be the host of the tænia—those who are uncultivated in their tastes, who are not over-dainty in what they eat and drink, and how. The axiom, "Not that which goeth into the mouth, but that which cometh out, defileth the man," is not literally or scientifically true. The swallowing of eggs or embryos is absolutely essential to the propagation of intestinal parasites. The belief that new-born children have worms needs to be corroborated by proof. Prof. Robley Dunglison makes the assertion that worms have been met with in the intestines of the fœtus in utero. This, if a fact, would be a strong argument against the theory that germs are only received from without.

But if we admit the theory of spontaneous generation to be correct, we will have to admit the generation of endless varieties. Worms have been met with in the eye, in muscular and cellular tissues. The strongylus gigas, which ranges in length five inches to three feet, is most generally found in the kidney. Warm climates and warm seasons of the year are more prolific of germ development than are the reverse conditions.

Heller says we are chiefly indebted for a right understanding of the conformation of the tænia to the investigations of Steenstrup on the alternation of generation. The tape worm must be looked upon as a colony of animals having an alternation of generation. The so-called head is the larva-like nurse; the segments of the worm—the proglottodes—are the animals with sexual organs. From the head, without any mingling of the sexes, are produced the segments by a process of budding. The segments remain joined together for a considerable time; but after they have come to maturity they separate from the rest of the colony. The head is provided with either two or four suckers, and very frequently with a circlet of numerous small hooks. By means of this apparatus, it fastens itself on to the mucous membrane of the intestines of its host. As the segments of the chain, the sexual animals, increase their distance from the head by the development and insertion of fresh segments, they become sexually more developed, increasing at the same time in size. They are hermaphroditic, and generate eggs, in which a six-hooked embryo becomes developed. If eggs containing these embryos find entry into the stomach of a suitable animal, their envelopes become softened or undone, and the embryos are set free. By some way or other they leave the digestive canal and make their way to different parts of the body. If they now meet with conditions favorable to their further growth, "nurses" are developed in them. Should these again happen to be introduced into the intestinal tract of another animal, they fasten themselves on, and another tape worm colony becomes developed by budding.

Tænia is a Hebrew word signifying a fillet; hence the name of the worm, from its resemblance to a tape or fillet. A tape worm will be fully developed from the embryo in about two months. The sexual organs are then fully grown, and segments are given off. The worm does not, as erroneously supposed, float its full length along the primæ viæ, but lies, coil upon coil, in the digested liquids. It has but very little power of progression or change of position. The worm is not possessed of a digestive tract, but the muscular constructions of the segments suck in their nutritive elements by their expansion and contraction much in the same manner as a hydraulic pump. Each segment is provided with a genital pore, which is seen as a protuberance on the lateral margin of the segment. The genital pore is placed irregularly from side to side, or not alternating regularly.

The three kinds of tænia most common in man, are the tænia solium, tænia saginata, and the bothriocephalus lata. The tænia elliptica is delicate, and varying in length from 4 to 16 inches, and frequents the dog and the cat. Tænia flavopunctata is also quite small, being from 8 to 12 inches long. The head of this species has never been found. The segments in both these kinds are much broader than they are long, or from 2½ to 5 times as broad as they are long. This worm is exceedingly rare, having been found but once

by Weiland. T. nana is exceedingly minute, being about $\frac{6}{100}$ of an inch long, the segments being 150 in number, and .018 of an inch broad. Tænia Madagascarinus has not been obtained entire, the segments being about five times as long or broad as the T. nana. The bothriocephalus lata is the largest of all the tape worms. Its head is about .08 of an inch long, and half as broad. The means by which the eggs or embryos are introduced is somewhat of a mystery, but as the embryos are provided with cilia, and are enabled to live and move about in the water for an indefinite time, it is not improbable that aquatic animals are the favorite nidus of these parasites. Its geographical distribution seems to be confined to limited areas, those areas being along the seas of Northern Europe, where the people subsist largely upon the fish taken in those waters. It is often found in the canine species, as well as in man. The bothriocephalus cordatus is so little known that we will merely enumerate it.

There is no possibility for the development of tænia, except as the embryos are introduced into the stomach by the eating of flesh or articles of diet which have been in contact with infected meat, or the imbibing of fluids in which embryos might be present. I know of no instance where animals other than the carnivora are subject to tænia, except such as are not over-nice or dainty—garbage-rooters, and bone-chewers. The hog or the cow are neither delicate nor æsthetic about the means of gratifying their thirst or appetite. My tænia patients have all been addicted to eating either raw ham or beef, or both. Persons who are in the habit of eating uncooked ham, are those afflicted with the T. solium, and those who eat rare beef, or that which has not been sufficiently heated to kill the vitality of the embryos, are as sure to be infested with the T. sag. Countries where the custom prevails of devouring the flesh reeking warm, and streaming with the blood, are the classic land of the tænia, and there all are tenanted alike with the tænia. The more that embryos abound in animals the more likely are they to be generated in man. Women are rather oftener subject to tænia than men, for the reason that they are more apt to eat raw meat during their culinary labors. The tænia are generally solitary, but are not antagonistic, for as many as forty have been found in the same person. And more than one species has been found to inhabit the same intestine at the same time. The segments of the T. sag are passed spontaneously, and the T. solium very rarely or never. As before mentioned, each segment or proglottodes is hermaphroditic. The segments of the T. solium are more clear, white, and delicate, while the segments of the T. sag. are broader, thicker, fatter, and less transparent than the T. solium. Some of the segments of the T. sag. are quite dark with pigment. The head of the T. solium is about the size of a pin head, and is provided with suckers and two circlets of small and large hooks, hence called the armed tænia. The T. sag. is about twice the length of the T. solium. Its head is much larger than that of the T. solium, being about $\frac{1}{10}$ of an inch broad. It also has four sucking discs, but no circlet of hooks, but in place of them a small frontal sucker. Owing to the absence of hooks, the T. sag. is called the unarmed tænia. The embryos in the cysticerous condition have been found in the brain, voluntary and involuntary muscles of the ruminants; embryos of the T. are not found in the human body, the chances for finding them not being offered. There is no doubt that the embryos of the tænia do exist in the persons who are infested with the animal. The T. solium is most common among pork-eating people, and the T. sag. in the ruminants, as the cow, calf, giraffe, goat, and sheep. The best measures of prevention or prophylaxis have already been enumerated.

The treatment, successfully, of tænia having been involved in the darkness of obscurity, has called to the front many quacks, or non-professional worm doctors. A patient of mine whom I successfully treated ultimately, was determined to consult a worm doctor, or specialist, in the city (*Kunkle*), as soon as I diagnosed a tape worm. Their fair treatment has brought them the enjoyment of eminent reputations. With good anthelmintics—plenty of deception on the part of the doctor, and credulity on the part of the patient—much satisfaction and many cures are effected. In the cure of tape worm, "cito, tuto, jucundo" (*quick, sure, agreeable*) is not absolutely true. It may be quick and sure, but not agreeable, for the remedies are, as a class, nauseating and unpleasant. The physician should be sure that he has expelled the whole worm, as only by this means, or else by a lapse of a few months without a return of expelled segments, can he know if a cure is effected. A cure cannot be by halves; it is complete, or no cure at all. The patient should take but little food for a few hours before beginning the more active treatment. Among the articles most obnoxious to the animal are onions, garlic, and salt herrings. Therefore, let the person partake of unsoaked herring salad and onions a few hours before the use of medicines. A light

meal of bread and coffee just about the time the medicine is taken will make the stomach much more tolerant of the nauseous dose. A cure should only be undertaken when a diagnosis can be made by the presence of the passage of segments. Persons who are suffering from acute febrile diseases, extremes of age, pregnancy, or menstruation, are not good subjects for treatment. Some diseases of the bowels are aggravated by the presence of the animal; and hence, such are cured of the parasite and its provoking disease. The only thing to warrant an attempt at a cure or a re-cure is the passage of segments detached or united. Among the most effectual of the many remedies for the extirpation of tænia are brayera anthelmentica or koosso in five-drachm doses, or koossin in thirty-grain doses, the oleo-resin of male fern or filix mas. This is the remedy upon which I have relied, and the one which has brought triumph to my banners. I have given it in half-drachm doses on retiring for the night, which generally brings the result the following day after the administration of a brisk purge. The bark of the pomegranate root has stood the test in the past. Pelletierine, its alkaloid principle is taking no second place as an exterminator of the hated animal. Rottlera tinctoria, kameela, benzine, saoria, or fruit of mocsa picta, oil of turpentine, and picronitrate of potash, have each effected cures, and each have their advocates, as they have been worthy of reliance. One little peculiarity or, perhaps, idiosyncrasy for which I found no fitting place in the body of this essay, is the dislike that a tape worm patient manifests for music. Dr. Eberle, who was cautious in his assertions and philosophical in his deductions, said: "It is stated by authors that persons afflicted with tænia become uneasy and ill whenever they hear music, particularly the music of an organ at church. This looks more like a conscience ill at ease than the morbus verminosus."

A patient of mine who was very fond of merriment and music, informed me that music had no attractions for him, and that if any one was playing or singing he would go away to where he could not hear it. I introduced this as a specimen of a rare character.

SYPHILITIC RE-INFECTION.*

BY J. G. BROOKS, M. D.,
Of Paducah, Ky.

GENTLEMEN: I desire to present, on this occasion, for your consideration, the subject of syphilitic re-infection, which, in my opinion, has not received that attention from the profession it justly merits. Especially is this true of the authors of standard works on venereal diseases. Few of them do so much as to mention the subject. We occasionally, however, meet with a very interesting and valuable article on this subject in some of the periodicals of the day, but these reports are so isolated as to be of little value to the general practitioner. One article appeared in the *Retrospect*, June 20, 1878, and, by the way, one of the best I have ever had the pleasure of reading. This report was from Gascoyne, Esq., of the Lock Hospital. His remarks are very forcible, and suggest valuable ideas well worthy of careful consideration. Ricord, with his vast clinical experience, never saw a case of re-infection; yet, he does not deny the possibility of it; indeed, he believed in the repetition of chancre. Ashhurst believes the protective influence of syphilis extends through all stages of the disease, so that a second attack of chancre, though possible, is exceedingly rare.

Bumstead and Dunker both fail to give us any light on this subject in their most excellent works, which is the case with all the authors whose books I have at my command.

Certainly it must have been overlooked by these authors, for I feel confident that within their vast experience and observation they have met cases of this kind, but failing to report them in journals, or to refer to them in the books, the medical world is comparatively in ignorance as to valuable facts connected with the subject.

During my brief connection with the profession, and within my limited experience, I have met two cases of re-infection, both of which went through all the evolutions of the disease the second time.

I have no notes of these cases, but being in almost daily communication with the parties, I have sufficient facts to enable me to report correctly.

Case 1. H., a bank clerk, consulted me in the winter of 1871–2, suffering with unmistakable syphilitic lychen, mucous patches on lips and tongue, with throat much inflamed and ulcerated. Inquiry enabled us to glean the following facts: He had had a chancre with enlarged lymphatic gland, followed by fever, restless nights, and an eruption. He had received a course of mercurial vapor baths, and both chancre and eruption disappeared, but lymphitis remained. I at once prescribed ¼ gr. hydrarg. proto-iod. to be taken

*Read before the Southwestern Kentucky Medical Society.

thrice daily, to be continued a fortnight, when I would change to calomel vapor baths. I touched the mucous patches in the mouth and on the tongue frequently with stick of silver nitrate. While the case proved one of great obstinacy, in less than twelve months all trace of the disease had disappeared. As I was about to leave the country to be absent for some length of time, and not believing the time had come when I could safely discharge him as cured, I commended him to Dr. J. W. Thompson, of our city. I returned in two years and found my patient as I left him, free from any syphilitic manifestations, he not having had any treatment in the meantime.

February 2, 1876—four years since last attack, or rather the disappearance of last attack—this man came to me with a typical chancre just behind the corona. Confrontation was had, and the woman with whom he had been cohabiting had a well defined chancre. In a few weeks this condition was followed by a general malaise and pains in limbs, which continued until a copious eruption, unmistakably syphilitic, appeared all over the body. The inguinal lymphatics of both sides were enlarged, and the post-cervical markedly so. This infection went through all stages of the disease as perfectly as did the first case, but proved much more obstinate; and this slow recovery caused my patient often to become low spirited and indulge in drinking to excess, together with other reckless habits, all of which was detrimental to a speedy cure.

In the fall of the same year, while on a drunken debauch, he so lacerated the penis at the seat of chancre that erysipelatous inflammation set in and rapidly spread over the groins, buttocks, and legs. After this was arrested, he was left in a much emaciated condition, and I advised him to go to Hot Springs, Arkansas, but not to take any medication, but confine himself to the baths and water alone. This advice he carried out, and I believe he is the only patient I ever knew permanently benefited by a visit to these springs.

Case 2. A county official, aged about 30 years, consulted me October 28, 1884, with a sore on his penis, and remarked, "I have a chancre, and want you to kill it before it gets in my blood. I had one once, and let it run until it poisoned my whole system." I examined the sore, and found my patient had made a correct diagnosis of his case. He had enlarged glands in both groins, but the post-cervical were not perceptible. After explaining how useless it would be to cauterize the sore, I prescribed proto-iodid. mercury ($\frac{1}{4}$ grain), taken three times daily.

On inquiry, I learned that he was treated for the previous case by Dr. Thompson, of this place, and I have since gleaned the following facts from him connected with the case:

April, 1873, had chancre, with marked lymphatic enlargement, followed by pains in limbs, with restless nights, and soon after by an eruption all over the body, mucous patches and alopecia—all of which yielded kindly to mercury, which was continued for one year.

The symptoms manifested in second attack were ulcerated sore throat, fissured tongue, with mucous patches, and a very extensive alopecia. So great was the falling of hair, that he lost all from the scalp, as well as both lashes and brows. The regular mercurial course had seemingly little or no effect in arresting this attack, and I resorted to the mixed treatment, with the happiest results, all symptoms disappearing in about eight months, and he has since remained well.

In the *Archives of Dermatology*, July, 1877, Dr. Von Vajda has reported a case in a young man only 24 years of age, who had had syphilis three times. This man was presented to the Vienna Medical Society, with remarks from Dr. Von Vajda on syphilitic re-infection.

Geo. Green Gascoyne, of the Lock Hospital, had three cases, as follows:

Case 1. November, 1863, a gentleman, twenty-eight years of age, in good health, consulted me for a large typical indurated chancre on corona, with indurated inguinal glands. He was prejudiced against mercury, and would not take it for five or six weeks, when, the chancre having increased to the size of a florin, and showing no disposition to heal, he commenced mercury. In a week the improvement was so marked that all reluctance ceased, and he continued the medicine three or four months, until the induration had quite disappeared. With the exception of a slight sore throat of doubtful character, there were left no constitutional symptoms.

November 16, 1867, he showed me an abrasion with a very suspicious base on the inside of prepuce, which developed into a chancre, inguinal enlargements, etc. The sore healed under mercury, but the induration did not disappear until February.

In May, a large indurated mass formed on frenum, and a similar deposit had taken place on dorsum of penis quite to its root. These indurations yielded kindly to mercury.

October following, a gumma formed on inside of leg, which ulcerated and proved an obstinate sore. Tertiary symptoms appeared in regular

turn, but health otherwise good; but these symptoms recurred the third time. He has since been free from the disease, and has two healthy children.

Case 2. February, 1864. Farmer, robust health, covered with eruptions—roseola and lichen—followed a sore now healed, slight induration remaining. Under mercury, symptoms disappeared and he remained free from disease until November, 1870, when he came with eruptions, roseola and psoriasis, mucous patches of throat, following a sore of one month's standing. The eruption commenced three weeks ago. Under mercury, these symptoms passed away, but he had several relapses of psoriasis, mucous papules of throat and anus, which received treatment at intervals until 1873. He has since continued well.

Case 3. January, 1864. A stout man, twenty-two years old, contracted chancre three months ago, which has healed, has now several mucous patches of throat and fauces, very extensive and persistent, with a fading eruption of roseola; he recovered under mercurial treatment, and remained free from all traces of the disease until May, 1873, when he showed me three indurated chancres on the under side of prepuce, the result of connection about a week since. Each sore was situated on a well-defined induration, and could be picked up between the fingers as a small button-like mass. The inguinal glands were affected. Mercury was given, and on the 24th of June following, the sores were nearly healed, but induration still quite perceptible. I have not heard of him since, though he promised to inform me if anything else occurred.

Case 4. June, 1865. A healthy man, 34 years. General roseola, with universal enlargement of glands, the result of infection probably in August, 1864. There had been great pain and aching of the limbs previous to appearance of the eruption. He had no treatment. In April he had very severe psoriasis of trunk and limbs, followed by iritis and great impairment of health. He continued in a cachectic state, having at intervals double orchitis, ulcers of legs, and nodes, until 1870, since when there have been no visible manifestations of disease; his health, however, has remained much enfeebled, and he has suffered from lung disease, considered to be of syphilitic origin.

February, 1873, a large indurated chancre formed on left thumb; it commenced as a pustule, and was contracted January 24th, from a patient who had a suppurating indurated sore on foreskin, which was followed by roseola. The induration on the thumb was well marked, and the lymphatics over the metacarpal bones became swollen, hard, and tender on pressure, but neither epitrochlear nor axillary glands were affected. During March there was much nocturnal aching of legs, but no other symptoms. He had no treatment.

From the *Philadelphia Medical News* of April 5, 1884, the following is from Prof. Newmann: He says, in discussing the important question as to whether syphilis can be acquired more than once, that it has not been witnessed by Barensprung, Sigmund, and Fournier, but has been met with by Diday, Zeissel, Bumstead, Hutchinson, Lee, and other equally careful and experienced observers. Newmann concludes, after carefully considering this subject, that syphilis rarely occurs but once in the same individual. Yet undoubted cases have been observed. The criteria of reinfection are a clear history of first infection, an initial lesion, enlargement of inguinal glands, and subsequent secondary manifestations. It is well known that a chancroid contracted during the time one is laboring under syphilis, is liable to become indurated at the base, so that a hard lesion seated on the genitals, without concomitant adenitis, and the consecutive constitutional symptoms, is not an indication of a second attack.

In conclusion, I will say that there is an opinion prevalent among the people that syphilis is an incurable disease; and that this false impression sprang from members of the medical profession, who, ignorant of both the nature and treatment of the disease, sought to shield under this guise their ignorance, and themselves from censure, should the patient fail to recover under their care, I have not the least doubt.

There is no fact more thoroughly established than that a person suffering with constitutional syphilis cannot be reinfected, and that the immunity thus afforded continues throughout all the stages of the disease. Then, if we have a patient presenting himself with chancre, we are forced to conclude that he has never had syphilis; or that he having had it, has been perfectly cured of the previous infection. Should investigation prove that he has had the disease prior to this, I will venture the affirmation that he has had the benefit of a thorough course of mercury, and at the time he became reinfected he was entirely free from the poisonous influence of the previous attack.

—Dr. R. W. Taylor, *Western Reporter*, claims good results from painting ring-worms twice a day with tincture myrrh, in which four grains of bichloride of mercury are added to each ounce.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM PEPPER, M. D., LL. D.,

Provost of, and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania.

Reported by William H. Morrison, M. D.

Diabetes Mellitus; Polyuria.

Gentleman: At the last lecture we considered the subject of diabetes, and I brought before you a patient in an advanced stage of the disease. There are one or two symptoms which were not exemplified in that case, but which will sometimes be met with. These are nervous symptoms of diabetes, the symptoms apparently connected with irritation of the nerves. Among these, one of the most marked is a sense of tingling and numbness complained of in the extremities, particularly in the feet and legs. This is perhaps partly due to defective circulation, but it also seems to be dependent partly upon a condition of the peripheral nerves. It is very like the sensation complained of by patients with spinal congestion or peri-neuritis. I am not sure that any alteration of the peripheral nerves exists, but the symptom is not unlike that complained of in such conditions. As the disease advances this feeling sometimes is a source of great complaint.

Another symptom is extreme irritation of certain parts of the surface, particularly of the orifices, as the vulva in women. Pruritus vulvæ may be among the earliest symptoms of which female diabetics complain. In the same way irritation of the end of the penis and irritation along the course of the urethra will be complained of by male subjects. Itching of the general surface of the skin is not rare. Diabetic eruptions, which may be either of an erythematous or of an eczematous character, are sometimes seen. Add these symptoms which are not so characteristic, to the more characteristic ones, to which I referred at the last lecture, and the history of diabetes is sufficiently complete.

You will remember that I described some of the types which will be met with, and had discussed the question of diet, and when the hour closed was speaking of the drugs which are useful in this affection. Before taking up the subject at this point, let me call attention to the specimens before us.

These were removed from a patient who consulted me some months ago. This lady, the wife of a physician, had a very obscure affection of the liver some three or four years ago. I did not see her at that time. There was violent pain in the region of the liver, occasional vomiting, some fever, and profuse hemorrages from the bowels. The liver was much enlarged and felt indurated. She was seen at the time by several experienced physicians, who regarded it as a case of carcinoma. It would appear, however, from the excessive pain, the local tenderness, the swelling of the liver, the vomiting, and the moderate fever, to have been simply a case of severe peri-hepatitis. As to the cause of the hemorrhage in the bowels I am not certain. Her recovery was slow. After the severe symptoms subsided and improvement began, her husband, who first brought her to me seven months ago, stated that she did not pick up as he had expected, and while the appetite was good, she did not gain much in flesh. During the previous year it had been noticed that she was passing too much urine. This did not attract much attention at first, and it was only some time later that sugar was found and the case shown to be one of fully established diabetes. From that time the symptoms were of a most characteristic type. There was progressive loss of flesh, the skin was dry and its secretions scanty, the appetite was strong but capricious, the digestion was rather weak, and there was distress in the epigastrium if the appetite were fully indulged. Thirst was only moderate. There was considerable nervousness and alteration of temperament. The quantity of urine was moderately increased, varying from 90 to 120 ounces. The amount of sugar, however, was very large. The specific gravity averaged about 1040. I was unable to find albumen in any of the cases which I examined.

Having heard this history of severe affection of the liver, with the subsequent development of diabetes, my attention was, of course, especially drawn to the condition of the liver. There was no evidence of marked hepatic disturbance. There had been no spells of pain as from biliary colic. The area of hepatic dullness was somewhat increased, but there was no unusual hardness.

A few days ago I received these specimens and the accompanying note, from which I take the following: "During the few past months she has been about the same, the sugar never diminishing. She lost some in weight, but was able to be about until March 1, when she complained of pain in the neck and side of the head. This was relieved by quinine. On the 3d, she suffered greatly with sickness of the stomach and bilious vomiting. On the 4th and 5th, she was the same. On the 6th, the sickness of stomach was better. The secretion of urine was the same in quantity as it had been for months; the specific gravity was down to 1025. There was a large amount of sugar. On the 7th, she became stupid and very restless, complaining of excessive pain over the region of the liver and stomach and running up to the right arm and shoulder. This pain and soreness had lasted for several days, but had not been so severe. That night the secretion of urine abruptly stopped. From that time the stupid condition gradually deepened, and for the last twelve hours, she was in a condition of profound coma, with decreased respirations until the end."

The case illustrates a point to which I desire to call attention, and that is, the modes in which diabetes may terminate. I have spoken to you of the prognosis, and in doing so, I stated that in general the prognosis was unfavorable as regards final recovery, but that it was favorable as regards prolongation of life. The most favorable cases are those in which the disease comes on in elderly gouty subjects, where there is only a moderate amount of sugar, and where the subjects do not lose weight, but continue well nourished and often fat, despite the presence of sugar in the urine. In ordinary cases, where the disease ap-

pears in middle life, the prognosis would be influenced by the quantity of urine and the quantity of sugar. It would be influenced very greatly by the effect which diet had upon the condition. When a moderate change in the diet produces a marked change in the urine and sugar, the prognosis would be favorable; but when in spite of careful regulation of the diet, the urine remains copious and the sugar abundant, the prognosis would be correspondingly bad. I also told you that the prognosis would be rendered unfavorable by the existence of organic affections, as of the liver, pancreas, or kidneys.

The disease terminates in various ways; sometimes by sheer progressive inanition, sometimes by the development of intercurrent intestinal disease, as diarrhœa. In a considerable number of cases it terminates in the development of phthisis. There is a great tendency to the development of phthisis in this affection, and when developed, it runs its course rapidly, and is not influenced favorably by any remedies. There is no form of phthisis more fatal than that occurring in the course of diabetes. Some cases terminate by gangrene, and it is well known that in diabetes slight injuries are apt to be followed by gangrene. An operation of small magnitude, as the amputation of a toe, may be followed by gangrene of the entire extremity, proving rapidly fatal. In some cases the mode of death is that which is illustrated by the case from which these two specimens were removed, that is, by uræmic or diabetic coma. A patient who has been in fair condition, but usually not doing favorably, suddenly presents a tendency to dullness. The urine is generally diminished in quantity. The dullness deepens into stupor and coma, terminating fatally in the course of twenty-four to forty-eight hours. The cause of this diabetic coma has been closely studied, but no completely satisfactory explanation has been arrived at. It is not improbable that in some of these cases there is, owing to the perverted chemistry of the body, a development of some complicated organic poison which acts as a deadly narcotic. In other cases, the coma may be due to the supervention of uræmia from renal disease. There may also be thrombosis of the cerebral vessels, which may explain the condition.

In this instance there was no post-mortem of the brain. "The liver was found much enlarged, extending from the third rib to an inch and a half below the margin of the ribs. Its weight was three pounds and eleven ounces. The gall-bladder was empty. The vena cava was distended with coagulated blood. The hepatic artery was enlarged sufficiently to permit the introduction of the index finger, and its branches were as large as goose quills; on section, its tissue was found deeply congested. The microscopical examination showed no pathological condition, except cloudy swelling and granular change in the liver cells." The specimen sent was not large enough to enable us to judge of the correctness of the remarkable statement in regard to the distension of the hepatic vessels.

The heart weighed eight ounces. There was an ante-mortem clot attached to the mitral valve, and extending into the pulmonary artery. The spleen was normal.

The kidneys show the presence of parenchymatous desquamative nephritis. They are much enlarged, the left measuring six inches in length. This bears upon the nature of the coma. In many cases diabetic coma is associated with nephritis, either acute or subacute. As I have stated, the urine was free from albumen the last time I examined it, which was several months ago. These kidneys present all the signs of subacute catarrhal nephritis, passing into the chronic stage.

Here then was a case of diabetes where there had been marked alteration in the liver, intense congestion, and severe peri-hepatitis. The diabetes ran its ordinary course, became complicated with nephritis, and terminated with diabetic coma.

Returning now to the treatment of diabetes, we shall consider the remedies to be employed. Every few months a new remedy springs up which is vaunted as a cure, but it soon falls into disuse. It will never be possible to find a remedy that is applicable to all cases, or capable of benefiting all cases, for the reason that diabetes is not one disease, but is merely a symptom of a great variety of diseases—not only of various diseases affecting one organ, but of different organs. Hence it is that there will never be one diet, or one remedy, which will be suitable for all cases of this affection. There are a few remedies which are applicable to a majority of cases. Among the remedies most generally useful are opium and codeia. These are well borne; indeed, there is a peculiar tolerance in diabetes, so that large doses of opium may be given without producing noxious affects. In some cases the greatest benefit in the way of decreasing the quantity of urine, diminishing the frequency of micturition, allaying the nervous irritation, controlling the exaggerated appetite, and lessening the quantity of sugar, will follow the use of these remedies; and when combined with a suitable diet the patient will be greatly improved. Indeed, sometimes there will be permanent improvement under this treatment. Where this is not accomplished, they act as valuable palliatives, and serve to hold the disease in check. In bad cases which are going down hill rapidly, they will afford great comfort and prolong life. They should not be used recklessly nor universally, nor until the most faithful attempts have been made by diet and hygiene. I have dilated upon the importance of diet, but I did not dwell upon the importance of rest, change of residence, change of occupation, and attention to every point of hygiene. When we remember how frequently this affection comes on after over-exertion, anxiety, and depressing causes, you will understand that strict attention to these points is of the first importance, and should be attended to before resorting to the use of any strong drugs.

Again, nearly all these cases require tonic treatment, attention to the digestion, and the use of such remedies as invigorate gastro-hepatic action. Pepsin, pancreatic extract, the mineral acids and the vegetable bitters, particularly nux-vomica and quinia, are often useful when given in some suitable form.

In the next place, most diabetic patients are benefited by the use of mild saline waters. There is perhaps no treatment of diabetes which has

commanded as much favor as the Carlsbad treatment, which consists in careful regulation of the hygiene, a proper diet, fine climate, total absence of business cares, with the free use of a dilute solution of sulphate of soda. Carlsbad water is a mild saline, with scarcely any laxative properties; its chief ingredient is sulphate of soda, and with this there is some chloride and bicarbonate of sodium and the like. This treatment gives admirable results in many cases of diabetes. We can imitate this treatment by exercising sufficient care in regard to the hygienic and dietetic conditions of these patients and recommending the use of some such water. This allays the thirst. There is a great craving for drink in this condition, and you will find that this is a point in the dietetic management which requires a great deal of care. Again, many of these patients require nutrient remedies, such as iron and cod liver oil, and these may be prescribed according to circumstances.

These are all, so to speak, fundamental or general principles. We come next to those special remedies recommended for special conditions. The bromides have been used in large amounts with the idea of obtaining their specific influence over the circulation and nervous system. In some cases they seem to do good, while in others they certainly do harm, and in all cases they must be used with great care.

Ergot has been used for its action upon the nerve centers and upon the walls of the blood vessels, so as to favor contraction of the vessels and thus lessen the excessive secretion of urine. Ergot in some cases of diabetes will greatly reduce the amount of urine, and will lessen, particularly in connection with proper diet, the amount of sugar. In other cases it does no good. It is directed only to this one condition, and has nothing specific in its effect. Salicylic acid and salicylate of sodium have proved useful in some cases. I have seen good results follow their use occasionally. Why, I cannot say. Possibly these were cases where there was a rheumatic or gouty diathesis underlying the diabetes, which was favorably influenced by the salicylates, and thus a good effect was produced upon the other symptoms of the disease. So I might go on and mention some hundreds of remedies which during the past fifteen years have been recommended in the treatment of this disease. The main reliance is to be placed upon hygiene, restriction of diet, and the general measures which I have recommended. In all cases, the treatment is anxious and unsatisfactory, yet with suitable care it is astonishing how long such patients can be sustained. In a considerable number of cases, under suitable regulation of diet, the quantity of sugar has decreased and sometimes entirely disappeared, so that the complete cure of diabetes by prolonged, judicious management, is not to be despaired of. You must not regard this condition as simply a subject for vigorous experimentation with drugs. It is much better to use no drugs than to do this. I should first direct a suitable hygiene and course of diet, and then cautiously employ remedies of a tonic, alterative, nutrient and sedative character, according to the special indications of the case. Medication should be suspended occasionally in order to see how the case is progressing. Do not drag the system down with excessive medication. We are dealing with a feeble digestion and feeble vitality, and should use remedies with great care. Just because we have the symptoms, excessive urination and sugar in the urine, upon which we can produce wonderful changes by powerful remedies directed to the nervous system, we must not be drawn into performing the experiment as though these symptoms constituted the whole disease, forgetting that they are only prominent symptoms of a highly complex, deep-seated and serious disorder.

Polyuria.

In connection with this subject it would be proper for me to briefly allude to the other condition in which excessive urination is a marked symptom, although the urine contains no sugar. This is known as polyuria, or diuresis. It is also called diabetes insipidus, but there is no excuse for this term. Insipidus simply means not sweet, while the use of the term diabetes at once introduces confusion. It should be termed polyuria, or diuresis. In this affection there is excessive urination, with the secretion of urine of low specific gravity, sometimes 1005 or 1008, and sometimes as low as 1002 or 1001. I have seen it as low as 1000.5. It is almost colorless, and at times almost like spring water. It contains no abnormal ingredient, no sugar, and no albumen. The normal constituents are present, sometimes in full quantities in the course of the day, sometimes somewhat decreased. It is needless to say that a quantitative analysis would give less urea and uric acid to each fluid ounce if the patient were passing 240 ounces than if he were passing only 30 ounces, but the whole amount might be equal.

The quantity of urine passed by such patients varies from five to fifteen pints, or even more. Diuresis occurs under various conditions. It may occur as a temporary condition in dropsical affections. A patient with an ovarian cyst will sometimes suddenly have a diuresis, with the discharge of all the contents of the cyst. I have seen this several times. In the same way, in hydrothorax and ascites, diuresis may occur, and the effusion disappear. It also sometimes occurs as a means of crisis in fevers and inflammatory diseases. A fever may terminate and copious urination take place. I have seen the finest instances of this in small-pox at the close of the eruption, when the quantity of urine has suddenly gone up to 200 or 300 ounces of spring-water-like fluid, and the patient returns from his bloated appearance to a natural condition, and may even appear shriveled.

Polyuria is a symptom of kidney disease, particularly of interstitial nephritis. As I have frequently told you, there may be scarcely a trace of albumen in the urine in this form of renal disease, but sooner or later careful examination will show the presence of albumen, and you will also find the cardiac affections, the rigid arteries, the increased arterial tension, and the other conditions which go with that general disorder of which interstitial nephritis is the chief local lesion.

Diuresis also occurs as a separate affection and not associated with the conditions mentioned. It is then largely under the influence of the nervous system. The influence of the nervous system in

producing copious urination is seen in hysterical cases and in depressed neurasthenic patients. There seems to be in some cases a deranged condition of the nerve centers and ganglia which control the circulation of the kidneys, and which thus allow an excessive drain of liquid from these organs. We find this disorder occurring in persons with sensitive nervous systems, usually anæmic, often with impaired digestion, and with a tendency to other nervous symptoms of a depressing type.

The diagnosis of this condition is of course very simple. The patient passes water often and in excessive quantity, of light color, low specific gravity, and containing no abnormal ingredients.

There are few, if any, general symptoms. The affection may last a long time and have very little effect upon the general health. The possibility of interstitial nephritis must always be borne in mind and carefully excluded.

If we can exclude nephritis, diabetes and serious intra-cranial trouble, the prognosis of this condition is favorable.

The treatment consists in the first place in careful attention to the general health, the removal of depressing causes, and the regulation of the diet. The digestion is to be improved and the anæmia removed by the use of suitable remedies. In these cases ergot produces good results and can be recommended. It is perhaps the best remedy for this affection. It should be given in increasing doses according to the tolerance of the system. So, too, we find that the bromides of the alkaline bases, the bromides of arsenic, of iron and of zinc, are all valuable in this condition. You will select one or the other according to the general condition present. The use of hydro-therapeutics, suitable bathing, and friction, is very desirable. The use of electricity is also serviceable, a mild galvanic current being employed.

The disease is not a very common one, and is more frequent in the young. It may have a varied significance. It is a symptom of different morbid conditions, so that its management will vary according to its particular pathological relations.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, September 3, 1885. The President, B. F. Baer, M. D., in the chair.

Dr. B. F. Baer read the following report of a case of

Ovarian Cystoma, Complicated with Peritonitis and Phlegmasia Alba Dolens. Double Ovariotomy.

Mrs. M., aged 31, has been a widow nine years; she had one child ten years ago, and had enjoyed good health until about three years before I saw her. At that time she observed that her abdomen was increasing in size. This gradually progressed for eighteen months, when she was large enough to attract the attention of her neighbors. After this, the growth remained almost stationary, and did not affect her general health until the latter part of March of the present year, when she was suddenly seized with pain in the left iliac region. The pain was acute and radiating in character, extending principally down the anterior portion of the left thigh. She attributed the attack to an unusual exertion. Although she made an effort to continue her avocation—that of seamstress—she was compelled to give up and send for her physician, my friend, Dr. John K. Haney, of Camden. When Dr. Haney first saw her, her abdomen was very tender over its entire surface, purple from congestion, greatly distended, and tympanitic in its upper, but dull in its lower portion. She was suffering great pain, and had constant nausea and vomiting; her skin was hot, pulse 120, and temperature 103°. From the history, symptoms, and physical signs elicited, the doctor diagnosticated ovarian cystoma, with supervening peritonitis. He administered quinia per rectum and morphia hypodermically, together with counter-irritation over the abdomen. Within a week, the patient appeared to be better, when through the kindness of Dr. Haney I first saw her. The tympanites had disappeared and the pain was not so severe, but the abdomen was still very tender on pressure, especially in the left iliac and right umbilical regions; her features were drawn and flushed, and presented an anxious expression; her tongue was dry and heavily coated, pulse quick, and temperature 102°. She lay quietly in the dorsal position, with her thighs flexed. The abdomen was as large as at full term of gestation, and was projecting. It was dull on percussion everywhere except along the line of the colon, and in the epigastrium, and there was evident fluctuation. The uterus was retroverted, not freely mobile, and very tender on pressure on the left side. Above and upon it could be felt the lower border of the circumscribed growth which occupied the abdominal cavity. I fully agreed with Dr. Haney's diagnosis of ovarian cyst, complicated by peritonitis. As she seemed to be somewhat better, I advised a continuance of the treatment as previously pursued, with the hope of obviating the necessity of ovariotomy during the unfavorable condition in which she then was. The peritonitis continued to improve slowly, but a new trouble presented itself in a very painful swelling of the left lower extremity. This continued until the limb was greatly increased in size. Its temperature was much higher than that of its fellow, which seemed to be in a normal condition. She now required large doses of morphia to relieve her pain, and she was losing flesh and strength. She still had nausea, and took almost no nourishment. Her temperature and pulse had again risen to the highest point noted. Both she and her friends were willing and anxious that we should do something more radical than simply to wait for a more favorable condition for operating if we deemed it proper. I believed, from the symptoms and physical signs, that the inflammatory action was external to the cyst, and not within it, and for that reason decided to wait for a subsidence of the acute symptoms, which I rather confidently expected. At the same time I held myself in readiness to operate at once, should the patient not improve or become worse. The next day she showed signs of slight improvement. Treatment, both local and general, continued.

The acute symptoms gradually subsided to those of a subacute condition. The temperature had decreased to 101°, pulse 100 but weak. She was still unable to retain food, and was extremely weak. I advised further delay. But she did not improve much after this, her temperature and pulse remaining about the same as that noted above. Her stomach had regained its power to a slight degree to retain and digest liquid food. She had now been confined to her bed more than two months; her left leg was powerless. There had not been the slightest improvement during the two previous weeks. We therefore decided to remove the tumor.

Operation.—June 19, 1885. Assisted by Drs. J. K. Haney, W. A. Davis, and H. M. Christian, and in the presence of a section of the class from the polyclinic, I made an incision three inches in length down to the peritoneum, and then checked the hemorrhage, which was free, with clamp forceps. I next very carefully incised the peritoneum, and found, as I had expected, that it was closely united to the cyst wall. These adhesions of cyst to peritoneum were universal, and it required careful and patient manipulation to separate them. The parts were exceedingly vascular, and hemorrhage was profuse. After separating it as far as possible, I tapped the cyst and allowed the contents, which were semi-liquid and chocolate-colored, to drain away I next closed the puncture made by the trocar, and then completed the separation of the cyst from its adhesions and removed it. As there was a very general and free oozing of blood from the broken vessel, I introduced a number of large flat sponges and spread them over the bleeding surface. An assistant now made firm pressure upon the external surface of the abdominal walls, whilst I ligated the pedicle and removed the tumor. The cyst developed in the left ovary, and the pedicle was slender, not unusually vascular, and of good length. The right ovary was diseased, contained a number of small cysts, and was double the normal size. I removed it also.

Examination now showed that the hemorrhage had almost ceased, but there were still a number of points from which blood flowed. The peritoneum was intensely injected, and I disliked very much to pick up bleeding points, for fear of making the hemorrhage worse. I therefore reapplied a large flat sponge, and had firm pressure again made from without, whilst I proceeded to place the sutures for the closure of the incision. I then removed the sponge and found very little blood upon it. I replaced it by a long, narrow strip of sponge, which I allowed to project from the lower angle of the wound, and then again cleansed Douglas's cul-de-sac and other dependent portions of the peritoneal cavity, after which I quickly tied the sutures from above downwards, removing the long sponge through the lower angle of the wound before I had encroached so closely upon it as to compress it in its removal. It was only slightly stained. I quickly applied the external dressing, making an unusual amount of pressure by cotton and bandage. The operation was finished, but the patient bore it badly. Her extremities were cold and purple, her face livid, and pulse very weak. Stimulants hypodermically and the application of external heat, which were begun during the operation, were continued after she was returned to bed. She remained in an almost collapsed state for many hours, but gradually reacted, and the next morning was in a fair condition. Her temperature was lower than it had been for weeks; pulse 112, but weak; stomach quiet; no pain; no tympany. She had taken an occasional small piece of ice, but nothing else, except the morphia, since the operation.

21st. Temperature, 102°; pulse, 120. Slight pain and tenderness in left iliac region; she had been very weak and faint during the night, for which brandy had been administered in repeated small doses. The swelling and pain in the limb had diminished. She had not vomited since the operation, and felt hungry. Ordered a teaspoonful of milk every second hour.

22d. Comfortable, and doing well. Temperature, 99⅘°; pulse, 90, and strong; slight metrostaxis; passed flatus per rectum. Milk increased to a tablespoonful, and retained.

24th. Temperature, 99°; pulse, 85; general condition greatly improved; no pain; no tympany; examined wound and found it united throughout; removed sutures.

25th. Doing well and is bright and cheerful. She took nearly a quart of milk during the last twenty-four hours and digested it.

30th. She has been gradually improving. Temperature normal; pulse 95; bowels moved to-day. She is taking solid food, and expresses herself as feeling quite well. Limb improving. She can now move it.

July 12. Sat up to-day for the first time, the twenty-second after the operation.

August 30. A note received from Dr. Haney to-day informs me that Mrs. M. is going about attending to some of her duties, but that she has not yet regained her strength fully, and that her limb is still weak.

The recovery of this woman under the forlorn circumstances just narrated is certainly a great triumph for our art; but the case serves a better purpose in forcibly illustrating the danger of deferring operative interference in ovarian cystoma simply because the patient is comfortable and suffering no inconvenience from the presence of the tumor. The subject of an ovarian tumor is in constant danger of injury from slight causes, which may produce such changes in the tumor as to render what might have been a simple and safe operation, one of extreme hazard. This had been a simple, slow-going cyst, and had not markedly affected the health during its three years of existence; yet it suddenly became inflamed, and the patient narrowly escaped death as a result. The case furnishes a strong argument in favor of operation as soon as the disease is diagnosticated. Of course, there are qualifications, and each case must be decided on its own merits; but the rule that an ovarian tumor should be removed as soon as it is known to exist, is the only safe one to follow.

As a striking contrast to the cure just related, and to show the value of the principle enunciated, I will report the following case of

Polycystic Ovarian Tumor, Double Ovariatomy.

A. K. was sent to me August 5, 1885. She was nineteen years of age, single. Puberty was

established at sixteen, and she had menstruated regularly until six months previously. She then without cause, so far as she knew, began to flow more freely at her periods, and they continued longer. About the same time she noticed a small lump in the right iliac region. This increased in size so that soon the entire hypogastrium was distended, and when I first saw her she was as large as at the eighth month of gestation. Her face showed marked signs of emaciation and pallor, and the drawn, anxious expression of ovarian cystic disease. She was then having a profuse metrorrhagia every two weeks. She had not suffered any pain, and up to within a few weeks very little inconvenience, except for the frequent metrorrhagia.

During the last month, however, her health had been failing. She had lost flesh, had a weak, languid feeling, and suffered much from the weight of the growth. Physical examination in the dorsal position revealed a projecting, slightly irregular abdomen, larger on the right side, dull on percussion over the entire anterior surface, but resonant along the line of the colon. Palpation showed imperfect fluctuation and several firm irregular masses within the abdominal cavity. The vagina was virginal, the cervix uteri was pointing forward, the body of the uterus retroverted; the whole organ enlarged and soft. It was only slightly movable independently of the tumor. The sound gave a measurement of three inches.

I diagnosticated polycystic disease of the right ovary, and advised immediate operation. Six days afterwards, August 11, she entered my private hospital, and on the 13th I operated, with the assistance of Drs. H. M. Christian and J. N. Richards. I made an incision two and a half inches in length, and came upon the surface of the tumor, which presented the white glistening nacreous appearance, especially common to thick walled polycysts. Tapped with Hodge's trocar. The contents were so thick that they flowed very slowly, and it was necessary to puncture several smaller cysts, which was done without removing the instrument. Even then the mass did not collapse much, because of a large number of young or child cysts. After closing the puncture, I enlarged the incision to three inches, but I had considerable difficulty in removing the tumor. It was necessary to make firm traction with rotatory movements, whilst Dr. Christian exerted a counter force and pressure through the abdominal walls. Fully ten minutes were occupied in delivering the tumor after it was tapped, but I was rewarded with an incision that looked so small that it seemed almost incredible that this large mass had passed through it. There had not been a single adhesion, but the pedicle was short, thick, and vascular. I tied it with Tait's Staffordshire knot, cut the tumor away and dropped the stump. The tissues of the left ovary were found to be entirely disorganized and degenerated into a cyst as large as a walnut. This I also removed. The uterus presented a very vascular appearance, and was somewhat enlarged. After assuring myself that the peritoneal cavity was entirely free from any foreign matter, I closed the incision, dressed the wound, and returned the patient to bed. Temperature normal, pulse 96. No pain, but as she felt a little sore and restless, $\frac{1}{4}$ grain of morphine was given hypodermically; small pieces of ice for thirst.

14th, 8 a. m. Twenty-six hours after the operation, milk in teaspoonful doses was allowed, water when she desired it.

15th. Metrostaxis began this morning.

18th. Union complete; removed sutures. Her recovery was uninterrupted. She sat up for a few minutes on the eleventh day, and went home eight miles in a carriage on the eighteenth day after the operation. To-day she sent a request to be permitted to go out, because she is feeling so well.

Certainly nothing could have been gained by procrastination in this case.

Dr. Goodell congratulated Dr. Baer on the good results obtained in such a serious case as that first reported. Great care in the asepsis of these cases should be observed. In one of his cases of septicæmia before the operation, after complete union had been secured, the stitches had been removed, and after the patient was up, an abscess was observed forming in the line of union, and was very persistent. Finally, after careful search, a ligature, which had been tied around the pedicle of one of the ovarian cysts, was found and removed. Subsequently, the other appeared, and after its removal the abscess healed.

He did not like to remove the stitches so early as Dr. Baer removed them; and he reminded Dr. Baer of a case in which he had assisted Dr. Goodell. The operation was performed on a December 5. Convalescence was rapid, and the patient was so impatient to be home on Christmas that she could not be restrained, and on the nineteenth day after the operation she took the cars for home. The train was derailed, and the jolting caused the cicatrix to open. The physician who was called in closed it immediately, and the patient recovered. In another case a cough caused the wound to burst open and reveal the bowels after the stitches had been removed. This patient also recovered. For these reasons he never removed the stitches before the eighth day, and not until the bowels had been opened.

Dr. Goodell inquired of Dr. Baer his method of closing the opening in the cyst after it had been tapped preparatory to its removal from the abdominal cavity. Does he employ pressure forceps? What method of dressing the abdominal wound?

Dr. Baer closes the cyst puncture with Wells's clamp forceps when the cyst wall is strong enough. In some cases he stitches up the opening, or ties a string below it when the cyst walls are loose and soft. He closes the external wound, as he had been taught by Dr. Goodell, with silk sutures, and dresses it with salicylated or absorbent cotton, adhesive strips to hold the cotton in place and take the strain off from the stitches, and over all a bandage. He removes the sutures on the fourth or fifth day in order to avoid the danger of pus forming in the suture tracks, as has sometimes occurred when he has allowed them to remain as long as eight days.

(*To be continued.*)

Dr. Holmes makes a suggestion in *The New Portfolio* to the effect that while a doctor's patients must put their tongues out, a doctor's wife must keep her tongue in.

EDITORIAL DEPARTMENT.

PERISCOPE.

Riggs's Disease.

G. A. Mills thus writes in the *N. Y. Med. Jour.*, July 25th:

At a meeting of the Connecticut Valley Dental Association, about eighteen years ago, at Northampton, Mass., John M. Riggs, M. D., of Hartford, Conn., was invited to make a proclamation (associated with a clinic) of his views concerning a diseased condition of the gums and the sockets of the teeth which often causes the loosening and falling out of the same. Up to this time nothing had appeared in the literature of dentistry except that which classed this disorder among the incurables, and it was spoken of as the result of senility; hence the common remark among people, "My father's and mother's teeth all dropped out, and it is only a matter of time with me." The removal of tartar as an external deposit upon the teeth was classed simply as an operation of scaling. This operation only recognized the foreign matter that could be seen. Dr. Riggs, in announcing his original views—while he gave it as his opinion that the deposits of tartar were the cause of the disorder under consideration—stated that his observation and experience matured the knowledge that there was a decided progressive inflammation existing under the gums and wasting both the hard and soft tissues, so that their attachments with the roots were gradually being destroyed. His knowledge of surgical principles suggested a practical application to these diseased localities, and he proceeded to the removal of all foreign substances from the roots of teeth, and the trimming of the necrosed edge of the alveolus to the life-line, leaving nature to restore to a normal condition. Dr. Riggs's view naturally excited a variety of comment—some expressing disbelief, and others accepting his novel ideas and statements. Not a few denied the existence of a necrosed edge of the alveolus. Dr. Riggs had devised a set of instruments well adapted for the treatment of this disorder, and these were unique and new, yet there was an effort on the part of a very few to dispute his claim to this invention; this did not prove a success. This body (the Connecticut Valley Dental Association) subsequently passed a resolution giving credit to Dr. Riggs for originality relative to the new pathology of the disorder now termed Riggs's disease, and so named at about that time in honor of Dr. Riggs. I have previously remarked that nothing of the doctor's views had ever been published so far as known. But—having become personally much interested in this disease, and in the discussion of it, and also finding my position regarding it misunderstood by several dentists—I was led to prepare a series of articles (six), which were published in the *Dental Cosmos* during the years 1876 and 1877, under the title of "What I Know about Riggs's Disease," in one of which articles I challenged the record of views corresponding to Dr. Riggs's. Since then not a word has come from any source to show that he is antedated in the matter. I may add that a confirmation of his views and their acceptance by many members of the dental profession have gradually taken place. I am glad to say that to-day it is the most prominent subject for consideration before dentists generally. Only a limited number, however, have come to a correct understanding of what is required, and how to meet the requirements. These few are demonstrating a successful treatment of the disorder. At this point of my article it seems advisable to introduce a feature which I shall elaborate later on; it is in reference to the technical term by which this disorder is now known, viz., *pericementitis*, substituted for the term well known by medical men—dental periostitis—meaning inflammation of the dental periosteum. This term (pericementitis) originated in the laboratory of Charles Heitzman, M. D., of New York city, during the late investigations made there by dentists under his instruction. The general subject of pericementitis it is not my design to discuss here, but it is necessary to make the distinction clear between Riggs's disease and general pericementitis. Riggs's disease is a peculiar phase of pericementitis; it may exist to the final loss of all the teeth, without a sign of any other phase of this disorder.

As the nature of this disease is so plainly embodied in my brief history of the matter which includes its pathology, it would seem that my readers need not be ignorant of its main features; therefore I pass to consider the diagnosis.

To diagnosticate an incipient case, or first manifestation, as it is often seen in the mouths of children (even at a very early age): The simplest form of the disease may often be seen at the peripheral part of the festoon of the gum-tissue, indicated by a congested appearance; by lifting this gum with a delicate instrument, there will be seen a little seed-like granule of calcific substance. Another case might show a deep red and raw-looking, elongated appearance of the gum-tissue about the necks of the teeth, and with or without any deposit; there may be also a looseness of the gum about the teeth, which causes quite a pocket. This latter condition is often a sequela of exanthematous disorders. The gums are often extremely sensitive to the touch. In the various cases we find general congestion, easy hemorrhage, pale and bloodless gums, a decidedly anæmic and frequently pimpled surface of the gums—the latter appearance in adults. Not uncommonly a first warning to the patient (adult) will be pain or tenderness about the tooth or teeth, and an examination will not reveal any decay, death of pulp (commonly called nerve), or evidence of inflammation of pulp. This is what I shall term a subtle manifestation, for it has been believed there could be no inflammation of the dental membrane without a disturbance of the pulp. This is now proved to be untrue, for abscesses do occur while the pulp remains normal. In a large proportion of cases there will be, on light pressure, a flow of pus from under the gums, and oftentimes it is a

copious discharge. This may be general, or it may be confined to a single tooth. Looseness of one or more of the teeth may be observed; also malposition, and this commonly after an occluding tooth is lost. I have given in detail enough of the manifestations to lead one even superficially familiar with unhealthy conditions to the diagnosis. It will be observed that I have omitted other conditions of disease that are manifested in the mouth, associated with the teeth and allied structures, viz.: syphilis, salivation, and scurvy. While in some instances these may be separated from the disorder in question, yet they are sometimes complications. I will mention another marked diagnostic feature associated always with an active stage of the disorder, and that is the odor which is distinctly noticeable to one familiar with Riggs's disease. There are other local manifestations that are, without doubt, largely influenced by the disease, but are commonly classed as expressions of constitutional debility, and still they may be wholly the result of the disorder under definition. This is proved by the arresting of the disease when the disabilities referred to are removed. Recession of gum-tissue is often seen, and no apparent inflammatory condition. While this is a peculiar phase, I maintain it is the same disorder. My term for it is atrophy of the gum-tissue—erosion of the tooth-structure, causing grooves across and around the necks of the teeth, not infrequently taking a serpentine direction. This also is a manifestation of the same disorder, as it is arrested by the treatment which will now be described.

Treatment.—As the nature of the disorder has proved to be novel, so will the treatment appear, as Dr. Riggs was the inventor of a set of instruments with which to perform the operations required in treating the disease. Each one is six inches in length, including the handle, which is of ebony and steel, octagonal and tapered; the blades are seven-eighths of an inch long, bent at an obtuse angle. The instruments are in two pairs, and there are two single ones. One pair has a knife edge and a safe edge; the other pair has the same, but these are reversed in their bevels—made so for the purpose of working at a different angle of the mouth, and from the operator instead of toward him. The single ones are double knife-edged, and differing in thickness of blade. Perhaps no better idea can be given of the general form of the blades than to say they resemble the half of a snipe's bill, the long, ovoid point being particularly adapted to ferreting out the intricate and deep-seated disordered parts of the hard and soft tissues about the roots of the teeth. In their dimensions they may seem ponderous to a novice, but in the hands of an expert no instrument can be more efficiently and delicately used. It must now be seen, by the description and location of Riggs's disease, that most of the operation is under the gum-tissue and out of sight, so that necessarily to know when the operation is complete at a given point can only be accomplished by an acquired and acute sense of touch. It may be said that the Riggs treatment has instituted a distinct and systematic mode of arresting the disease. Rightly understood and rightly practiced, I regard this treatment as the most efficient in dental surgery. The severity of the cases differs according to constitutional conditions, and, if the dentist is the doctor, he will know whether the patient can be wisely aided by constitutional treatment. The prognosis must be based upon the conditions as they appear in each case.

From an extensive experience within the last ten years in the treatment of a large number of cases, and the success attained, I am justified in saying that Riggs's disease can no longer be classed among the incurable ones.

It is perfectly plain that this disease is not confined to any one period in life. Under the age of forty I have had numerous cases in the most active stages of progress—so noticeable that there was almost spontaneous hemorrhage of the gums, and such an excessive flow of pus that the service of napkins for absorbing was required in sleeping hours. These facts can be testified to by well-known physicians. As one impressed with the prevalence of Riggs's disease, and its destructive effect on the general health, I should be remiss in duty if I were silent, or neglected to call the earnest attention of medical men and the public to the grave facts, for they have had too little consideration. I would say emphatically that the most serious complications may arise, and the worst septic conditions may be threatened and encountered, from pure neglect. That one disorder not arrested calls others of a more serious nature into existence, is a well-known fact among medical men.

Chronic Endo-metritis, Cervical and Corporeal, with Prolapsus Uteri.

Dr. W. E. Buxton thus writes in the *Cinn. Lancet and Clinic*, July 25:

A history of this case is given for the purpose of showing what a train of symptoms and diseases can follow another disease and be cured by simply removing the original cause.

As taken from my notes: Was called to see Mrs. R., aged 27 years, blonde, medium build, of volitive and encephalic temperament. I found her suffering from the above malady. She had been previously treated by two neighboring doctors with but little success, and to the dissatisfaction of herself and husband. After making a thorough examination of the case (nothing short of a thorough one will ever develop the true nature of such cases), I informed her of her condition, and told her I thought by careful treatment and time she could be relieved. Thus the case was given into my hands for treatment.

Her condition was not very encouraging. She was decidedly anæmic, confined to her bed most of the time, pulse very feeble, tongue slightly red and pointed, severe pain in the head extending from frontal to occipital region; sometimes a burning, hot pain in the top of the head. She would feel dizzy whenever attempting to walk, would become despondent and melancholy upon hearing any strange news; feet and hands would become cold every evening and bathed in a cold, clammy perspiration; general myalgia, habitual constipation and gastric disturbance. She had a dry, hacking cough, which might lead us to suppose her lungs were involved, but they were not; the parenchymatous substance was

normal. Another very persistent complication was the functional heart trouble. She was determined to believe her heart badly diseased, as she expressed herself, but I found no valvular, neither organic lesion whatever; although paroxysms of dyspnœa had occasioned alarm to her friends time and again. Of course we will find quite frequently such symptoms in the hysteric patient, but this case was free of hysteria.

Several years ago she commenced suffering with a burning, hot pain, in the hypogastric region, pain extending down left leg, also in left side and shoulder. She complained of a pulling-down pain in the lumbar region continually; menstruation was very irregular, sometimes amounting to menorrhagia; a profuse leucorrhœal, alternating with a sanguineous discharge would, appear between the monthly molimen. Upon digital examination the os could be plainly felt near the external orifice of the vagina, fundus leaning posteriorly and to the region of the left ovary; the neck was considerably enlarged, very sensitive to the touch, and indurated. Examination per speculum showed the neck engorged, inflamed, and a follicular disintegration of the os.

Upon introducing the sound or sponge-mop, there would be a tenacious muco-sanguineous discharge, also disease products would adhere to the mop when first withdrawing it; any pressure against the fundus would cause excessive pain.

This was the condition of the case when I commenced treating her; the lady to-day is well in every respect, excepting a slight gastric catarrh, which is not amenable to any treatment I have given her. Conception did not, and I think could not, take place for four years, but she is the happy mother of two children since.

As the treatment for this case was successful, it may be of interest to some one else. First, I gave her the following tonic:

℞.	Mur. tinct. ferri,	f. ʒij.
	Quinia sulph.,	ʒj.
	Tr. nux. vom.,	f. ʒss.
	Brom. pot.,	ʒj.
	Syrup auranti,	ʒij.
	Aquæ,	ʒvj. M.

Sig.—Teaspoonful, three times per day after meals.

Continued this for two months, discontinued for one week, then gave two months longer, when I discontinued it altogether. I then gave her:

℞.	Sulph. mag.,	ʒij.
	Mur. tinct. ferri,	ʒj.
	Aquæ,	Oj. M.

Sig.—Wineglassful every morning in half a glass of sweetened water, before meal.

While taking internal remedies, I had her use the vaginal injection of hot water for 20 minutes every night, followed by the following:

℞.	Acid carb.,	gtts. x.
	Zinci sulph.,	ʒj.
	Acetate plumb.,	ʒss.
	Morph. sulph.,	grs. v.
	Aquæ,	Oj. M.

Inject two ounces every night. The hot water injection would cleanse the vaginal cavity of all discharges, as well as have a contracting and soothing effect, and the astringent last, to give strength and vitality to the weakened wall of the vagina. As a local application to relieve the follicular ulceration of both cervix and body of the uterus, I applied the nitrate of silver, 20 grains to the ounce of water, every eight days. My method of using the silver is with a sponge mop. Introduce a small one first through the neck, saturated with glycerine, so that you can apply the caustic to the fundus without producing the astringent effect in the cervix before reaching the fundus. I continued this for two months, then I relied solely on the hot water and astringent injection.

After using the tonic she gained in strength, had a healthy color, gained in flesh, the rigors and general malaise was relieved, her menses became regular and normal. The constipation was overcome by the sulph. mag. mixture. The uterus returned gradually to its normal position. Sanguineous discharges ceased. Sound could be introduced to fundus without pain, and I believe, had I not used the local remedies unceasingly, the trouble in the uterine cavity would have been in the same, yes, a more painful condition to-day than it was then. The slight palpitation that remains gives her no more trouble than it did in the virgin state, and as its severity was vastly dependent on other grave symptoms that are comparatively cured, so have the frightening paroxyms of dyspnœa been controlled.

These cases may seem old to read about—however, they are just as obstinate to treat now as years ago, with the same appliances and remedies (and even more so); but we are advancing in our mode of treatment, and with strict attention, close observation, and a gentle hand, we can stand death off quite often, and put many a poor, suffering woman on safe ground once more.

A Case in which a Patient Removed Forty-three Calculi by a Novel Method from His Own Bladder.

Dr. James Murphy thus writes in the *British Medical Journal*, August 8, 1885:
